The second important aspect of Japan's geography is its mountains, which cover 72 percent of the land. This has led to some political fragmentation throughout much of Japan's history, although its extensive coastline helps tie Japan together through communication by sea. The mountainous landscape has also severely restricted the amount of available farmland, forcing Japanese peasants to intensively cultivate what little land is available. This has led to both a crowded and necessarily cooperative society that values the group, loyalty, and obedience to authority over the rights of the individual. The introduction of Confucianism after 400 C.E., with its emphasis on strictly defined social roles, further reinforced this trend.

Finally, except for forests, which cover 55 percent of its land, Japan is poor in natural resources. This has forced

its people to be resourceful traders and manufacturers, especially since the late 1800's when the Industrial Revolution vastly increased Japan's dependence on outside resources. Overall, Japan's geography, in particular its isolation, caused civilization to come considerably later than it did elsewhere for many of the high civilizations of Eurasia.

Early elements of Japanese culture. Early Japan seems to have had a number of different peoples migrating to its shores and influencing its early culture. Among the earliest were the Ainu, a Caucasian people quite distinct from the Mongolian stock that most Japanese are descended from. Some 17,000 Ainu still inhabit the northern island of Hokkaido. However, the primary influences on Japan's early culture were of Mongolian stock. From about 250 B.C.E. to 300 C.E., a culture from Asia known as Yayoi predominated, introducing rice agriculture, iron and bronze technology, and weaving. Yayoi society seems to have been matriarchal, with women holding high positions as priestesses or shamans. Only much later in Japanese history would women be reduced to a more subservient role in society.

By the third century C.E., cultural influences probably introduced from Korea, in particular better iron weapons and fighting from horseback, led to the Yamato period of Japanese culture (c.300-710). At first, the country was divided between numerous warring clans, known as *Uji*, each with its own patriarchal chief and guardian deity. Gradually, the Yamato clan unified most of Japan under its rule, claiming divine descent from the sun goddess Amaterasu. The imperial family in Japan today still traces its lineage back through the Yamato clan in the fourth century. Since there was no real distinction between governmental and religious functions in early Japan, the imperial family's duties have always been largely concerned with religious ritual. The burden of these ritualistic duties would hinder the emperors in the exercise of real political power so much in later centuries that they would often abdicate their thrones to their sons so they could be free to rule.

The emperors were especially concerned with their duties in Shinto, a uniquely Japanese religion that was emerging at this time. Shinto, which means "Way of the Gods" and is still popular in Japan, concerns itself with reverence for the forces of nature, which affect Japan so profoundly (e.g., typhoons, earthquakes, and volcanoes). It has no written texts or organization, being centered on shrines to local deities, known as *kami*. Worship is simple, consisting mainly of clapping (to get the kami's attention), bowing, and possibly making offerings.

Shinto largely focuses on ritual purification to remove impurity caused by contact with physical dirtiness, sex, childbirth, wounds, and death. The modern Japanese insistence on baths and cleanliness probably derives from this aspect of Shinto. The most important Shinto shrine at Ise is sacred to the sun goddess and has helped provide a national focus of loyalty to the imperial family associated with that deity.

Growing Chinese influence. By the fifth century C.E., the growing power and sophistication of the Japanese state was making Japanese society more open to the influence of Chinese culture coming in by way of Korea. (A list compiled in 815 C.E. showed that more than one-third of Japan's aristocratic families claimed ancestry from Korea or China by way of Chinese colonies in Korea.) In addition, two other factors fed into this influence. For one thing, the Uji system of individual local clans was inadequate for meeting the growing needs of the state, oftentimes challenging or disrupting its authority. Secondly, the T'ang dynasty, which took power in 618, was taking China to new heights of power and influence that were being felt especially in Japan.

Two of the most important influences from China were Buddhism and Confucianism. In 552, the Korean state of Paekche presented scriptures and an image of Buddha to the Yamato court. Despite initial resistance by Japanese nobles, the Soga clan, which then effectively controlled the emperor and government, won Buddhism's acceptance. An important side effect of the introduction of Buddhism was the introduction of Chinese writing to Japan. This led many Japanese scholars to study in China where they would pick up other aspects of Chinese civilization and bring them back home. Thus Buddhism served as a vehicle for spreading Chinese civilization in much the same way that Christianity spread Mediterranean civilization to North Europe.

Confucianism brought two important elements to Japanese culture. First of all, its stress on a strict hierarchy of relationships reinforced the already cooperative nature of Japanese society as well as the autocratic social and political order that would emerge. Second, the Confucian emphasis on merit and education as the means of advancing in government would have some effect on Japanese values. However, this concept of advancement by merit would meet with stiff resistance from the hereditary Japanese nobility.

In the early 600's, Chinese, in particular Confucian, influence, sparked a number of governmental reforms.

First of all, in 603 and 604, Prince Shotoku advocated the Chinese concepts of a supreme ruler, a centralized bureaucracy, advancement through merit, and the Confucian virtues. He tried to accomplish this by creating a system of court ranks that would replace the hereditary Uji ranks as the major basis for status. Prince Shotoku also sent several large embassies to China whose main importance was to bring back even more Chinese culture, which further accelerated the process of Japan's cultural transformation.

The Taika reforms and rise of the Japanese state. By 700 C.E., the central government was ready for the next step in consolidating its power: the Taika ("great change"). This set of reforms tried to apply Chinese governing techniques and institutions to Japan in several ways: the establishment of central government ministries, provincial government, law codes, and a taxation system modeled after that of T'ang China. Central to these reforms was a census to redistribute lands to the peasants, although the emperor in theory owned all these lands and parceled them out among his loyal followers. In 702, these reforms were formalized in the Taiho law codes. At the same time, the government established its first permanent capital at Nara, which was modeled after the Chinese capital, Ch'ang-an, being laid out in a rectangular grid along a north-south axis.

The Taika reforms and Taiho law codes increased the power of the emperor and court, but with some typically Japanese modifications. For one thing, the Japanese never adopted the Chinese doctrine of the Mandate of Heaven, which justified revolution against corrupt rulers. Therefore, the same dynasty of emperors has kept the throne in Japan throughout its history to the present day, however unqualified some of them may have been. Second, resistance by the hereditary Japanese nobles against the Confucian system of promotion by means of an examination system meant that birth, not merit, remained the main criteria for government office. Finally, since dues to an overlord were cheaper than taxes to the central government, many peasants commended their lands to monasteries and powerful court nobles whose lands were tax exempt. This created a narrower tax base for the government and a greater tax burden on the peasants who kept their lands. Despite these limitations, the Taika reforms and Taiho law codes were still a major step forward in the development of the Japanese state.

Earthquakes in Japan

The devastating tsunami that hit Japan following the earthquake in 2011

Earthquakes. Another major problem sporadically hitting Japan throughout its history has been earthquakes, since it rests on the convergence of the Pacific, Eurasian, and Philippine Sea tectonic plates (below). In 1857, an earthquake devastated Tokyo, killing 107,000 people, a much worse toll than the 1906 San Francisco Earthquake, which took 3,000 lives.

Even more devastating was the Great Kanto Earthquake that struck Tokyo on September 1, 1923, triggering what certainly ranks as one of history's greatest "perfect storms" in terms of catastrophes. The quake hit with an estimated strength of 7.9, snapping buildings in two. Being midday, there were already thousands of charcoal fires burning to prepare lunch. The quake combined these to set the city, which was largely made of wood and paper, on fire. The conflagration was ferocious enough to generate a firestorm with high winds that further stoked the fire, further intensifying the winds, and so on.

Meanwhile, the earthquake had triggered two other effects: a tsunami and a series of landslides that swept away and/or buried entire villages with bodies and flying debris. The fires raged for three days, leaving 60% of Tokyo and 80% of

Yokohama destroyed, along with an estimated 142,807 people killed.

By comparison, the earthquake that hit northeastern Japan in March 2011 was an estimated 9.0 in strength, over ten times the strength of the Kanto Earthquake. Despite even greater population density, Japanese diligence in preparing for such a disaster in terms of earthquake proof buildings, warning systems, and a well-drilled population saved thousands of lives that would have otherwise been lost.

Another striking aspect of Japanese culture revealed in the aftermath the 2011 earthquake was the orderliness of the Japanese people. There were virtually no incidents of looting or fighting as people waited calmly and patiently in lines for hours on end to receive what few supplies were available or just to make a phone call. Just as remarkable was the way those people would go back and share their meager supplies with their neighbors.

Early Japanese Society

An AINU chief photographed in the 1920s

The AINU, Japan's aboriginal inhabitants, were gradually driven to the northern parts of Japan. Originally Caucasians from Siberia, they may have spoken an early form of Japanese, which is totally different from Chinese. Referred to as *emishi* (barbarians) and "earth spiders", they were tough fighters whom early emperors recruited as guards. Many Samurai traditions (e.g., curved swords) were likely taken from the AINU. Based on how one classifies them in terms of ethnic purity, the estimated number of remaining AINU ranges from 20,000 to 200,000.

Women's status in early Japanese society was relatively high, as seen in the prominence of goddesses in Japanese mythology and of women (who might even lead in warfare) in early legends. One legend was that of a sorceress Pimiko, who supposedly lived shut up with 1000 women and one man who was used to communicate orders to her subjects. A Chinese traveler in 238 CE) reported that southwestern Japan was ruled by sorceresses. Ancient custom of female rule continued to 700's CE. Not until the 1400's as Japan was becoming more urban did women assume totally submissive roles. And even then, women of samurai rank might be proficient with weapons, especially a form of pole arm known as the *niginata*.

The legendary Japanese Empress Jingu (169-269 CE) conquering Korea. The lack of information about her brings even her existence into doubt, especially since there is no evidence of Japanese rule in Korea at this time. Most likely, she was an historical character with considerable influence at court, if not full regal power.

Another early Chinese account said Japanese lived on raw vegetables, smeared their bodies with pink and scarlet pigments, and divined the future from baked bones.

Shinto

The “floating tori-e” near Hiroshima. Such gateways marked entrances to Shinto shrines

Shinto, "Way of the Gods," sees any mystery of nature as a kami (divine spirit). It has traditionally stressed the importance of family, communal life, valor, and fidelity, as well as submission to authority (at first to the clan and later to the state) and, at times, even an aggressive militarism. Since the emperor was essentially the high priest for Shinto, it emphasized his divinity and has served as a basis for national unity.

Shinto stresses purity and cleanliness, which is still strongly evident in Japanese culture. Polluting oneself through contact with death, disease, blood, or childbirth required cleansing oneself by bathing in a stream and then fasting. Much like in India, occupations that involved polluting acts, such as burial of the dead, were confined to an untouchable class known as *eta*.

Shinto shrines are simple structures symbolizing the virtues of purity and austerity. Often they are just surrounded by a fence and/or trees planted round a square. If there is a building, it rests on plain pillars and is covered by a thatched roof. The *Tori-e* (ceremonial entrance to a Shinto shrine), is a portal of two curved quadrangular beams atop two round pillars.

The shrines have no images, just a symbol, usually a mirror, recalling a legend that the sun goddess, Amaterasu had brought down three symbols: a curved jewel, sword, and a mirror. Shinto priests are a hereditary class and can marry.

JAPAN FROM COURT SOCIETY TO THE RISE OF THE SAMURAI (794-1573)

*"There are three things which I cannot control,
the fall of the dice, the flow of the River Kamo,
and the turbulent monks of Mount Hiei."--*

Emperor Go-Shirakawa

Heiankyo and Japanese court society (794-1184).

By the eighth century, the Japanese state had developed to the point of establishing a permanent capital at Nara. Unfortunately, at the same time, the power of the Buddhist monasteries was getting out of control. One Nara temple alone possessed forty-six manors and 5000 acres of excellent farmland, all of it tax-free. As we have seen, peasants often commended their lands to the monasteries in order to avoid government taxes. When a Buddhist monk, Dokyo, exercised undue influence over the empress Koken, this triggered a reaction against women running the government that reduced their overall status in society. It also caused the next emperor, Kammu, to move the capital away from the monasteries. Following the example of the T'ang dynasty then at the peak of its power in China, he founded a new capital at Heiankyo, meaning "Capital of Eternal Tranquility". The new city, modeled after the T'ang Chinese capital, Ch'ang-an, but on a smaller scale, was laid out in a rectangular grid facing South with the palace at the north end.

Since Japan was isolated and faced no foreign invasions at this time, Heiankyo had few fortifications and was little concerned with military affairs. It was able to maintain control over most of Japan through peaceful means. However, thanks to the non-military character of the government, two elements of Japanese society were creating problems that eventually would weaken Heiankyo's control. First of all, the power and rivalries of the different Buddhist monasteries often got out of control. These monasteries went so far as to form their own armies that fought each other and disrupted the public peace. Another source of trouble came from the Ainu on the frontiers. Japanese settlers and nobles claiming new lands had

to spend much of their time fighting these primeval inhabitants. As a result, these frontier settlers became both tough fighters (ancestors of the Samurai) and increasingly independent.

For the time being, however, a powerful landed family, the Fujiwara, was able to maintain effective control over both the countryside and the emperors, through whom they ruled. They used the power that came from their extensive landed estates and exercised a skillful diplomacy of playing one faction off against another to control the nobles in the countryside. Their influence over the emperors and the government came from their ability to marry their daughters into the imperial family. By this time, the emperors were also so burdened by their ritual duties that it was increasingly difficult for them to exercise real power. Thus the custom of indirect rule, a dominant feature of Japanese history, became firmly entrenched during the centuries of Fujiwara influence.

Thanks to the peace and security provided by the Fujiwara, a handful of idle nobles in Heiankyo were able to participate in the brilliant, if somewhat artificial and inbred, culture that court life offered. Much like the French nobles at Louis XIV's court at Versailles, these nobles engaged in activities where manners, taste, and fashion counted for more in gaining status than did accomplishing anything more substantial. Careers rose and fell on the basis of the choice of colors for clothes and stationary or the proper phrasing in a poem. Long hair, blackened teeth, and eyebrows that were shaved and repainted higher on the forehead were the marks of beauty for women. A continuous round of love affairs, cuckoo viewing expeditions, and winding water banquets, where men would drink from floating cups of wine and then compose poems, occupied their time.

Our best source for getting the flavor of this court life comes from the pen of a woman, Lady Murasaki, who wrote one of the greatest works of Japanese literature, *The Tale of Genji*, whose title character spends his life in search of true love. Interestingly, women at court tended to write the

best literature since, unlike men who had to concern themselves with the precise calligraphy of the difficult Chinese writing system, they could use the more phonetic Kana script. As artificial as much of court life at Heiankyo may have been, it did have a profound effect on later Japanese tastes in such things as art and poetry.

Despite the positive influences of this court culture, it had several factors working against its continued existence. For one thing, it was cut off from the realities of mainstream society and its powerbase in the countryside. Also, the Taika reforms and Taiho Law Code were meeting with growing resistance from both nobles and peasants. Along these lines, the peasants' practice of commending their lands to local nobles and monasteries to avoid government taxes seriously cut into government revenues. As a result, the central government's power and the influence of the Fujiwara family in particular declined. This led to the rising power of the provincial warlords, which further accelerated the decline of the government, and so on. The resulting turmoil triggered a civil war between the two most powerful noble clans, the Taira and Minamoto, both of whom were originally minor offshoots of the imperial family who had gone to the provinces to make their fortunes. In the end, the Minamoto, who had the backing of the shadowy emperors in Heiankyo, won the civil war and the title of *Sei-tai-shogun*, meaning "barbarian suppressing generalissimo". The shortened version of this title, *shogun*, would be the one that most effective rulers of Japan would carry until 1868, ruling indirectly through the emperors who still carried on as ceremonial figureheads.

The Kamakura Shogunate and rise of the samurai (1185-1333). As the term shogun suggests, the Kamakura Shogunate that the Minamoto established was in essence a form of military rule. This contrasted sharply with the highly cultured but non-military regime that preceded it in Heiankyo, and was referred to as the *bakufu* ("tent government") to reflect this military nature. Gradually, the shoguns replaced the formal government centered in Heiankyo with a strongly run feudal administration

that rewarded their followers with income from estates and offices in the provinces. In 1221, a retired emperor who was resentful of this erosion of the central government's power rebelled in what was known as the Shokyu War. The shoguns easily defeated this uprising, which allowed them to extend their feudal government all across Japan.

Feudal rule in Japan was very similar to its counterpart in Western Europe at the time. This was especially true of the warrior class that served as the backbone of the feudal order, known as the *bushi* ("warriors") or *samurai* ("those who serve"). Much like the European knights who were descended mainly from the Germanic invaders who had overthrown the Roman Empire, the samurai were largely descendants of the old provincial uji aristocracy, each group inheriting its military traditions from its respective ancestors. Both groups were an elite aristocracy, since the arms and armor needed to fight were too expensive for most people. Both groups also fought primarily from horseback in a series of individual encounters that often required the exchange of courtesies that befitted warriors of an elite class. Opposing samurai would greet each other with their respective genealogies to ensure they had worthy opponents, compliment their defeated opponents' courage afterwards, and even burn incense in their own helmets so their heads would smell good if they were decapitated (a common practice in samurai combat, largely to prove one's victory).

The Samurai code of honor, later known as *Bushido* ("Way of the Warrior"), demanded selfless loyalty to one's lord. Much like in Western Europe, the lord-vassal relationship was a reciprocal one, where the lord gave his vassal protection and income from land or an office in return for lifelong service. However, in times of turmoil when the law of the jungle prevailed, many samurai would quickly change loyalties according to the shifting fortunes of war and politics. Samurai were also expected to display unflinching bravery in combat and bear incredible hardships without so much as complaining. Even to feel pain and hunger, let alone show or express it was considered a dishonor.

Such values tended to breed a certain callousness for human suffering and disregard for human life which later shocked Westerners when they came into contact with Japan.

Many of the same virtues were expected of samurai women, who were taught to repress their feelings, ignore suffering, loyally serve their husbands, and in some cases to handle weapons. Women handled household affairs, including money, which was considered beneath a warrior's dignity. Even today, Japanese women typically handle family finances, probably deriving from this custom. At first, a samurai woman could inherit her husband's property and take charge of her family affairs and deceased husbands' duties to his lord. But, as time went on and warfare became more chronic, women's property rights declined and they found themselves reduced to an increasingly inferior position in society.

Japanese arms, armor, and techniques of combat were quite different from their counterparts in Western Europe. Unlike European knights who used the lance as their primary weapon, the samurai relied primarily on the bow and their splendid curved swords, probably the finest crafted blades anywhere. As a result, the samurai's sword became the material focus of his honor, and a whole tradition and mythology grew up around both Japanese sword making and their swords. In contrast to the heavy plate armor which evolved in Western Europe, samurai armor was made up of thin strips of steel held together by brightly colored threads, making it much lighter and more flexible, while still providing a good deal of protection.

The strong rule established by Minamoto Yoritomo continued under his widow, Masa-ko, and her father, Hojo Tokimasa (1138-1215). Afterwards, the Hojo clan established a regency (1205-1333) that controlled the shoguns who in turn were supposedly running Japan in the name of the emperors. The Hojo Regency ruled Japan with a firm and somewhat just hand. In 1232, it established a guideline for jurists known as the Jōei Code. Magistrates were expected to find and

carefully weigh evidence in trials. (If that failed, they would then look for some evil omens, such as nosebleeds, choking, or being wet upon by a crow or a kite) to decide the case. Society was divided into three classes (samurai, commoners, and slaves), but did not always give the upper classes better treatment. Women's status was still relatively high. They inherited land, administered offices, and even led troops into battle. One of them, Masa-ko who was Minamoto Yoritomo's widow, even acted as the power behind the throne after her husband's death.

The Hojo Regency saw two problems arise that would bring about their eventual fall. First of all, the peace and prosperity it brought encouraged the rise of a middle class. Although the samurai looked with disdain upon people so concerned with money, prosperous times did influence them to imitate the more elegant and expensive lifestyles carried on at court. At the same time, the rising money economy triggered rising prices. As in Western Europe, this inflation hurt the samurai, especially the poorer ones who, besides being on static fixed incomes from lands and offices, were also not very good at handling money. As a result, many samurai found themselves in difficulties, some of them becoming unattached and footloose bandit samurai known as *ronin* who would add to Japan's troubles in the future.

The second problem came in 1274 when the Mongol ruler of China, Kublai Khan, launched his first invasion of Japan. Although this was driven back by a typhoon, the Mongols returned in 1281 with a much larger force of some 140,000 men. Despite the Mongols' numbers and use of such weapons as catapults that fired explosive projectiles, the samurai fought furiously to repel the invaders. However, once again, it was the force of nature in the form of a typhoon that decided the issue by wrecking much of the Mongol fleet and saving Japan. The Japanese called these typhoons *kamikaze* ("divine winds"), feeling that Japan was specially protected by the gods.

The Mongol invasions had forced the Japanese to band together as never before in the common

defense of their nation. However, the cost of fighting the invaders had been a tremendous burden for the Hojo government. It had also led many samurai to expect rewards from the government for their efforts. Unfortunately, since the Hojos had gained no new lands or plunder from these wars and could not meet samurai expectations of rewards, they lost many of their followers' support. Therefore, because of both economic strains and dissatisfaction among many samurai, the Hojo Regency and Kamakura Shogunate gave way to the weak rule of the Ashikaga Shogunate (1338-1573). The government's weakness allowed local lords, known as *daimyo*, to assert their independence. Eventually, Japan was split into some 60 virtually independent states whose daimyos disrupted the public peace with their private wars.

Japan's First Capital, Heian-Kyo

Daibutsu temple, the world's largest wooden building was built in Nara, Japan's first capital until 794 when the government moved to Heian-Kyo.

***Establishing a permanent capital* was hindered by the fact that it was considered a ritual impurity every time an emperor died, so they had to keep moving the court until some way was found around this conundrum.**

***Heian-Kyo* means "Capital of Eternal Tranquility". Instead of heavy fortifications it was protected by forests or mountains to the east, west, and north, while the Yodo River provided transportation for supplies into the city. More than anything, Heian-Kyo's sacred nature helped protect it from attack during this period.**

The original Heian-era imperial residence, built when the capital was moved from Nara in 794.

Like the Chinese capital at Chang' an, Heian Kyo was laid out in a rectangular grid with the imperial palace in the North at the end of the main avenue, which was 100 meters wide. Other broad avenues where the nobles lived were flanked by trees. While the city had a population of 100,000, the court itself only contained about 3,000 people who maintained a highly inbred and insulated culture. Adding to this isolation was the decline of the Tang Dynasty after c.750 C.E., which cut Japan's contact with China to a trickle. Therefore, any Japanese nobles interested in culture tended to concentrate at court where the Fujiwara could watch them.

***The Sanjuusan Gen-do temple* at Kyoto has 33 images of Buddha along with 1001 statues of other protective Buddhist deities.**

***The Chinese court rank system* was closely copied by the Japanese, with the top five ranks allowed to wear special clothes and enter the emperor's audience chamber. Rank also provided court officials income from peasant estates, allowing them to stay at court.**

***The monks on Mt. Hiei* outside Heian-Kyo were especially powerful and troublesome, deriving**

their power from the fact that Mt. Hiei was north-east of the imperial city, the direction from which it was believed evil spirits attack cities. Therefore, Mt. Hiei was considered sacred for its role in protecting the capital.

Scaring demons away at court was the job of palace guards who periodically twanged their bowstrings.

Court Life at Heian-Kyo

Thanks to the peace and security provided by the Fujiwara, a handful of idle nobles in Heian-kyo were able to participate in the brilliant, if somewhat artificial and inbred, culture that court life offered. Much like the French nobles at Louis XIV's court at Versailles, these nobles engaged in activities where manners, taste, and fashion counted for more in gaining status than did accomplishing anything more substantial. Careers rose and fell on the basis of the choice of colors for clothes and stationary or the proper phrasing in a poem. A continuous round of love affairs, cuckoo viewing expeditions, and winding water banquets, where men would drink from floating cups of wine and then compose poems, occupied their time.

Heian fashion. During the Heian period fashion counted for everything. Women shaved their eyebrows and redrew them higher on their foreheads. Long hair was highly valued, especially if it were longer than woman's height. Both sexes chose to have their faces painted white. A woman would typically wear five layers of silk robes, although it might run up to 30. However, if she got a shade just slightly wrong,

she could be mercilessly subjected to humiliation and gossip.

Among men it was fashionable to wear a small patch of beard on their chins and headgear that made them look like quails. Men made perfume blending a fine art so that one could identify a man in a dark room by his scent. They also cultivated good manners, such as knocking on a lady's door by scratching it with their pinky fingers.

Black teeth. Among the stranger practices at the Japanese court was the custom of staining one's teeth black with a mixture of oxidized iron shavings melted in vinegar and powdered gallnuts. The thought was that white teeth look glaring and hideous. During the Muromachi period (1336-1568) lower classes adopted this practice, starting from the age of puberty. In the Edo period (1603-1868), married women were required to dye their teeth black.

One of the more popular court entertainments was the winding water banquet where one who came upon a floating cup of wine had to take a sip and compose a poem on the spot. Another popular event was viewing the harvest moon

from a dragon boat, a ceremony that is still carried on today.

Other leisure activities were cherry blossom viewing tours, cuckoo viewing, and Chrysanthemum viewing festivals where participants would write poems and then drink wine steeped in Chrysanthemums. Heian women rarely went outdoors, although in winter they were occasionally allowed to go out and roll in the snow.

Japanese writing has used three different scripts. *Hiragana* is one of two Japanese syllabaries termed as *kana*, the other being *katakana*. *Kanji* are Chinese characters used to write certain parts of the Japanese language. They have different semantic value in Japanese than they have in Chinese, but phonetically they are the same. There are literally thousands of kanji characters.

Men at court wrote the more difficult kanji, made all the more challenging by the emphasis put on calligraphy. Women wrote in the simpler kana script, sometimes referred to as women's writing. However, this freed women to write more, and most of what we know about Japanese court life was written by women.

The Tale of Genji. The most notable example of "women's writing" is Lady Murasaki Shikibu's *The Tale of Genji*, an epic romance about the pursuit of love. While it spans several generations, it mainly concerns the title character's search for love, even with common women and a 10-year old girl whom he raises and marries as his fourth wife. *The Tale of Genji* has remained one of the most popular works of

Japanese literature down through the centuries, inspiring numerous commentaries, one of which written in the 1200's was 54 volumes in length.

Courtship and romance at Heian-Kyo. Since young women lived secluded lives, the only way for a man to know whom he might want to court was to spy on women in their private chambers. As a result, such peeping toms (below) were tolerated in Japanese society.

The preliminary move in courting a woman was to write a poem, using just the right syllables and paper with appropriate color and folding. The lady and her confidants would carefully scrutinize such notes to decipher their true intentions and seriousness.

If interested, the lady would send a messenger with a reply. Such messengers often played a vital role in getting two lovers together. Once together, a couple might think they were sharing an evening alone, but the paper-thin walls of Japanese homes must have made it possible for outsiders to eavesdrop, thus making true privacy nearly impossible to attain.

Japanese Warrior Monks

Ironically, some of the most troublesome elements in Japanese society were Buddhist monks. Their preferred weapon was the *niginata*, a curved blade at the end of a long pole. Unlike the West, where there were constant doctrinal disputes, monks in Japan mainly fought over the appointments of leaders of their monasteries. Rioting warrior monks, known as *sohei*, would demonstrate in the streets in support of their leader. To further intimidate the populace, they might bring out their *mikoshi*, a sacred image rarely seen in public.

Sohei would even exercise spiritual blackmail where they would bring a mikoshi and set it in front of an enemy and then go home. The enemy, fearing the god's wrath, especially if anything happened to its image, would beg for its removal and agree to the soheis' terms.

Over time, warrior monks became involved in broader political struggles. In 1180, during the civil war between the Taira and Minamoto clans, a band of them even burned the old capital city, Nara in 1180.

The Gempei War (1180-85) and Foundation of the Shogunate

Minamoto & Taira forces clash in a battle offshore.

Six degrees of separation. During the Heian Era, minor branches of imperial family had to move to frontiers after six generations at court. Two such branches, which then built up independent power bases in the countryside were the Taira and Minamoto clans.

During this period of turmoil, roads and seas were plagued by bandits and pirates. Not even the capital, Heian-Kyo, was safe, being beset with looting and the burning of homes, while dead women and children remained unburied in the streets. At one point, the Taira sacked Kyoto and captured the Minamoto leader whose own officer killed him before the Taira could take him alive. Then he killed himself.

Initially, the Taira forces won a great victory, causing the Minamoto to enlist the aid of the powerful Takeda clan. The Takeda launched a surprise morning attack against the Taira who were hung over from drinking too much sake the previous evening. Despite this victory, the Taira won the first round of the Gempei War and seized power, running the government much like the Fujiwara had, intermarrying into the imperial family and succumbing to the soft life at court. As a result, they lost touch with the tougher provincial nobles, allowing the Minamoto to regroup for a comeback and start a new civil war (1180-85). In the end the

Minamoto won a decisive victory in a naval battle on an inland sea, allowing them to take control of Japan.

Minamoto no Yoritomo, winner of the Gempei War and Japan's first Shogun

The toughness of Japanese warriors is seen in the story of a 16-year old fighting for the Minamoto who was shot in eye who would not fall until he had killed his opponent. When a colleague put his foot on boy's face to help pull out the arrow, the boy threatened to kill him for the dishonor of putting his foot on his face.

The Way of the Warrior

The Kamakura Shogunate and rise of the samurai (1185-1333). As the term shogun suggests, the Kamakura Shogunate that the Minamoto established was in essence a form of military rule. This contrasted sharply with the highly cultured but non-military regime that preceded it in Heian-kyo, and was referred to as the *bakufu* ("tent government") to reflect this military nature. Gradually, the shoguns replaced the formal government centered in Heian-kyo with a strongly run feudal administration that rewarded their samurai followers with income from estates and offices in the provinces.

Bakufu, often translated as "tent government", was originally a screen set up in camp where a general could confer with his officers.

Shogun, like the old Roman office of dictator, was originally given just for the duration of a particular crisis.

Feudal rule in Japan was very similar to its counterpart in Western Europe at the time. This was especially true of the warrior class that served as the backbone of the feudal order, known as the *bushi* ("warriors") or *samurai* ("those who serve"). Much like the European knights who were descended mainly from the Germanic invaders who had overthrown the Roman Empire, the samurai were largely descendants of the old provincial *uji* aristocracy, each group inheriting its military traditions from its respective ancestors. Both groups were an elite aristocracy, since the arms and armor needed to fight were too expensive for most people. Both groups also fought primarily from horseback in a series of individual encounters that often required the exchange of courtesies that befitted warriors of an elite class.

Buhshido ("The Way of the Warrior") demanded an almost religious commitment to military life. Much like chivalry, its counterpart in the West, it evolved from simple feudal loyalties into a powerful and elaborate ethical code, which is still important in Japan today.

"A samurai should live & die sword in hand...To be brave & warlike must be his invincible condition."

"When his stomach is empty, it is a disgrace to feel hungry."

Much like in Western Europe, the lord-vassal relationship was a reciprocal one, where the lord gave his vassal protection and income from land or an office in return for lifelong service. However, in times of turmoil when the law of the jungle prevailed, many samurai would quickly

change loyalties according to the shifting fortunes of war and politics. Samurai were also expected to display unflinching bravery in combat and bear incredible hardships without so much as complaining. Even to feel pain and hunger, let alone show or express it was considered a dishonor. Such values tended to breed a certain callousness for human suffering and disregard for human life which later shocked Westerners when they came into contact with Japan.

Service to one's lord was supposedly more important than loyalty to family or fear of death itself. However, many samurai were more opportunistic than legends would like us to believe, especially in times of turmoil. Similarly, as times became more turbulent, old rules of etiquette, such as when the Taira and Minamoto would initially agree to a site for battle, tended to give way to ambushes and even aiming to kill an enemy's horse.

Seppuku (AKA *hari-kiri*) was ritual suicide by a samurai, introduced in the 1200's. Seppuku might be ordered for a violation of the samurai code of conduct or done voluntarily at a lord's death, for feeling disgraced, to atone for mistakes or transgressions, to protest unjust actions or to dissuade lord from certain course of actions. After the defeat of the Hojo's, thousands of loyal samurai killed themselves. Similar actions also took place during World War II.

Seppuku was done by slitting across one's stomach with a knife, a particularly painful (but honorable) way to go. Consequently there often would be someone holding a sword with which to behead the subject right after he slit his stomach, thus making for a quick and relatively painless death.

Before committing *seppuku*, a Samurai would typically compose a suicide poem by which to be remembered.

In the Tokugawa period *seppuku* became so common it had to be banned in 1663 to keep the samurai class from killing itself off.

Samurai arms and armor. The samurai were descended from horse archers who fought from small Mongol ponies. Therefore they developed light flexible armor, largely consisting of scales (lamellae) of lacquered iron laced together with colorful silk cord (top picture). This made the armor as flexible as mail, but much tougher, and also light enough (c.25 pounds) for a samurai to leap through rice paddies or over castle walls and, at the end of the day, be able to fold it up and store it in a box.

Because of their custom of decapitating slain enemies, samurai wanted especially strong head and neck armor. Therefore their helmets were made of riveted iron, with special neck protectors and a metal facemask to scare their enemies.

Left: a samurai helmet showing the reinforced neck. Right: The author in a replica of a samurai helmet & mask

The samurai's sword was the material focus of his honor, and losing one's sword was ultimate

dishonor. A newborn was presented with a sword in the crib, slept with it all his life, and was buried with it. Japanese swords were the best of their day. The most treasured swords were battle tested heirlooms, and were thought to be magical with lives of their own, giving rise to a host of legends about them and sword smiths.

Sword-making. The technique of sword-making revolved around the dilemma of making them either hard but brittle or flexible but soft. Sword smiths came up with an ingenious combination of the two by hammering out a sandwich of hard & soft steels, folding it over and repeating this process over 20 times. This created a blade with over a million layers, giving it a hard outer cutting edge and flexible inner blade.

The final step was to cover the sword's outer edge with clay and heat it at dawn until the sword smith could see it glow and then, reciting a prayer, plunge it into water. The exposed edge cooled instantly while the inner edge cooled slowly producing a blade that was both extremely hard and durable.

New swords were tested on bundles of straw, corpses, and even condemned men. One such convict said he'd have swallowed stones if he'd known his fate.

Japanese sword smiths would sometimes attain legendary status. Two of the most famous were the rival sword smiths, Muramasa and Musamune, who had a contest to see whose sword was sharper by sticking their swords up in a stream. Muramasa's sword cut all the leaves, but the leaves avoided Musamune's sword, so he won.

The Japanese bow was the samurai's other main weapon. It took arrows 4 feet long and had a range of 45-110 yards. Minamoto bows were supposedly so strong it took 3-5 men to stretch them. Unlike most bows, the Japanese bow was held below the center, probably to make it easier

to fire from horseback. Such a bow took years to master, and often became a central part of the training of Zen monks.

Combat. According to custom and tradition, before battle, a samurai would announce his name, ancestry and previous deeds to ensure he fought a worthy opponent. However as warfare intensified in Japan, especially with the introduction of firearms, a samurai often didn't have the time to announce his lineage before enemy musketeers shot him. Thus for quick identification of soldiers on the battlefield, they attached *sashimono* (Japanese for banner) to their backs.

Warriors faced each other on horseback, first shooting between 20 and 30 arrows at each other. Once their arrows were depleted they would charge on horseback with their swords. However, since it was hard to kill an opponent from horseback with one's sword, they would wrestle each other to the ground and try to slit their opponent's throat with a dagger.

"...to cut into the enemy all alone, and die unseen by any witnesses is a futile action. This is called a 'dog's death'..."

Witnesses of deeds of battle were required if one were to be rewarded, so after combat the victorious samurai would compliment his slain foe for his courage and then decapitate him to serve as proof of his deeds. Before battle some samurai would scent their helmets with incense so their heads would smell nice if they fell in battle.

The head-viewing ceremony was an important part of a samurai's life, since it confirmed his

deeds in battle and qualified him for a reward from his lord. Before the ceremony the victorious samurai's women relatives would clean, comb, and scent (with incense) the heads being presented. They also applied cosmetics to make them look alive, tag them with paper identifying the slain and victorious warriors, and mount them on spiked boards for presenting.

Samurai women. Many of the same virtues required of samurai men were also expected of their women, who were taught to repress their feelings, ignore suffering, loyally serve their husbands, and in some cases to handle weapons. Women handled household affairs, including money, which was considered beneath a warrior's dignity. Even today, Japanese women typically handle family finances, probably deriving from this custom. At first, a samurai woman could inherit her husband's property and take charge of her family affairs and deceased husbands' duties to his lord. But, as time went on and warfare became more chronic, women's property rights declined and they found themselves reduced to an increasingly inferior position in society.

Jigai was the female samurai's own version of suicide. Their method was to cut the jugular vein for a quick and relatively painless death, usually to avoid capture by enemies. One other feature of *jigai* was tying the legs together to ensure the woman maintained a dignified posture in death.

The Mongol Invasions

The typhoon that seemed to miraculously come up to destroy the Mongol invasion fleet in 1281 was dubbed *kamikaze*, meaning (divine wind). Later Japanese use of this term for suicide pilots in World War II led to the mistranslation of *kamikaze* to mean suicide.

The first Mongol invasion (1274) was triggered by Japanese refusal to bow to a veiled threat from Kublai Khan and killed his ambassador. An expedition of 15-30,000 Mongols first landed at Tsushima where the small garrisons fought and died to a man. When the Mongols moved to Kyushu, the local samurai, rather than waiting for reinforcements, threw themselves furiously at Mongols in one on one combat.

Not having fought a major war in a century, the samurai fought with the old ideas of challenging their foes and reciting their pedigrees. But first they had to get through the hail of Mongol arrows and firebombs launched from catapults. However, after a bloody but indecisive battle at Hakata, the Mongols returned to their ships, which were then wrecked by a storm.

The second Mongol invasion (1281) was the largest seaborne invasion in history, bringing and estimated 150,000 men. Nevertheless, the Samurai once again recklessly assaulted the Mongols and drove the first wave back from beach, while the smaller Japanese ships wreaked havoc on Mongol fleet. Faced with overwhelming numbers, the samurai sent a message for the imperial family to pray. Soon after this, a 2-day typhoon blew up and wrecked the Mongol fleet. As a result this raised the

status of the emperor, who naturally claimed credit for this seeming miracle

CHAOS AND REUNIFICATION: JAPAN TO THE RISE OF THE TOKUGAWA SHOGUNATE (1338-1639)

The breakdown of centralized rule and the rise of the Daimyo. The Ashikaga shoguns who took over in 1338 found themselves faced with many of the same problems that had led to the downfall of their Hojo predecessors, namely resistance from outlying regions of Japan and continuing turmoil caused by bandit samurai (ronin). In addition, two other things weakened the Ashikaga government. First of all, the emperor Godaigo, rather than remaining a shadowy figurehead, challenged the Ashikagas for power. Although he was defeated, his revolt further weakened the shoguns. Secondly, the Ashikagas engaged in expensive building projects that cut into their already diminishing tax and estate revenues. As a result, many constables, the shoguns' officials in the provinces, started assuming more power locally, further weakening the central government.

This triggered revolts and the assassination of the shogun in 1441. A regency of four competing houses followed, which only led to more feuding and the Onin War (1467-77). Although a settlement was patched up, the damage was already done, leading to a period known as the Age of Warring States, dominated by new provincial warlords known as *daimyo*. The turmoil of the age created a good deal of social upheaval, which allowed many ambitious men of lower class origins to rise to positions of power. (Among these would be Toyotomi Hideyoshi, a peasant who would eventually unify most of Japan under his rule.) Contributing to the era's social mobility was the introduction of European muskets in 1542. This led to growing reliance on peasants for the daimyos' armies, some of which had three peasants in the ranks for every samurai. Another impact of the age's upheaval was women's declining status, largely the result of wider enforcement of primogeniture in order to prevent the splitting of family estates in these dangerous times. Therefore, women lost most of their property rights and became little more than pawns in the power politics of the day.

The roughly 142 daimyo who controlled Japan at this time were virtually independent rulers who fought each other viciously for survival and power. For about a century, rival daimyos plundered towns,

devastated the countryside, and massacred innocent civilians. However, many or most daimyo, seeing that a healthy society was essential to their power, closely supervised their estates and encouraged economic improvements, especially through public works such as irrigation projects. This helped create more settled conditions, which had three major results. First of all, much like in Western Europe, the more settled conditions and improvements in agriculture led to the rise of towns. These generally started as markets under the protection of the daimyo's castle walls and then grew into full-fledged towns with a middle class of moneylenders using both cash and credit.

Second, the more settled conditions and a desire for trade combined with a growing problem with Japanese pirates, known as wako, made Japan more open to trade and relations with Portuguese explorers who were then first entering East Asian waters. This was because wako raids on the mainland had caused the Ming dynasty in China to cut trade relations with Japan. The Japanese, who were especially anxious to get silk from China, saw the Portuguese, who could trade in China, as useful middlemen to that end. In addition to trade, two other very different things came into Japan with the Portuguese. One was the manufacture and use of firearms in warfare, which spread rapidly across Japan. The other influence was Christianity, which was spread by Jesuit missionaries who displayed great self discipline and concentrated on the upper classes, both of which features the Japanese samurai liked. As a result, many samurai and even daimyos converted to Christianity. Both firearms and Christianity would later lead to growing stresses in Japanese society.

Zen and Amida Buddhism. Another effect of the more settled conditions then prevailing was a cultural flowering in Japan. This largely centered on a new Buddhist sect known as Zen. Up to this point, the most popular form of Buddhism was Amida, or the Pure Land, sect. Unlike Theravada Buddhism, whose members thought that it took personal effort to attain Nirvana through the extinction of the self (which they felt was an illusion anyway), Amida Buddhism's followers saw Buddha and the Bodhisattva (other mortals who had gained enlightenment) as deities who would help them reach a paradise to the West. While this paradise was originally meant to be merely a sort of

halfway spot where people could attain final enlightenment, many people saw it as an end in itself.

Amida Buddhism came to resemble Christianity in several ways. For one thing, it based salvation on God's grace. Second, it conceived of Buddha as something of a Trinity in the doctrine of the Three Buddhas: the body of Essence, who was the primordial Buddha pervading the universe, the Created Body, which was the historical Buddha much like Christ, and the Body of Bliss which takes the form of many Buddhas. The most important of these is Amida Buddha (Immeasurable Glory) who dwells in the Western paradise. Also, like Christianity, Amida Buddhism concerned itself with good works and charity. By the fifteenth century it was the most popular form of Buddhism in Japan, and it has kept that distinction to this day.

However, by this time another form of Buddhism, Zen (Chinese *Chan*), was becoming especially popular with the Samurai. Zen, which had reached Japan from China in the sixth century, emphasized reliance on one's own efforts rather than the grace of Buddha to attain enlightenment. As a result, it never achieved the popularity of Amida Buddhism. The basic idea of Zen is that there is an underlying unity tying everything together; but we are trapped in our daily perceptions by the illusion of a distinction between ourselves and the world around us. The goal of Zen is to be able to perceive the reality of that unity and extinguish our egos that create the illusion that separates us from all around us. This is not done through rational means, since rational thought is the product of minds that still perceive a subjective and objective world where things are separate from one another. Rather, Zen strives for enlightenment (*satori*) through an intuitive grasp by means of meditation and concentration.

One primary techniques to this end is the *koan*, which, from the rational point of view, is an illogical riddle or theme meant to break the mind's customary thinking and "derail" it from its normal rational patterns of thought. The strain that the koan puts on the conscious mind should liberate the subconscious and break down the barriers between the two, thus leading to enlightenment. Another technique is *zazen*, a strict meditation using proper posture, breath, and concentration that stills the

mind, controls the emotions, and strengthens the will. Unlike the koan, which through its "illogic" suddenly shakes one into enlightenment, *zazen* generally attains a more gradual enlightenment. However, *zazen* was more popular with the samurai, since its emphasis on discipline helped them develop their military skills, while its ideas on life and death (which in Zen are one and the same) helped them face death in battle with more resolve. Interestingly, such martial arts as swordsmanship and archery came to be closely associated with Zen, a far cry from Buddha's original intentions.

Zen, with its emphasis on harmony, purity, tranquility, and simplicity, had a profound impact on several aspects of Japanese culture during this time. One was the tea ceremony, which had also been imported from China several centuries earlier. This ritual, where one person served tea to another, took place in a simple hut and emphasized simplicity through the precise arrangement of objects and the equally precise motions in the ceremony itself. Ceramics and flower arranging, which were inherent parts of the tea ceremony, also became important aspects of Japanese culture at this time. Zen also influenced the development of Japanese gardens, and in particular rock gardens of raked gravel (to represent the tranquility of the sea) interspersed with larger rocks arranged in precise and asymmetrical patterns. The beauty and simplicity of these gardens were designed to help one in meditation.

The restoration of order and unity by Oda Nobunaga and Toyotomi Hideyoshi (1551-98). Although these various cultural advances were not of a political nature, they did help provide Japan with a common culture that promoted the unity of Japan as a whole. At the same time, the rising towns and middle class along with the spread of firearms and Christianity were available for anyone with the daring and foresight to exploit them in the reunification of Japan. That person, Oda Nobunaga, came to power in a relatively obscure but strategically placed province of Owari in 1551. He and his successors, Toyotomi Hideyoshi and Ieyasu Tokugawa, would restore unity and order to Japan.

Nobunaga was a cruel and ruthless tyrant who once had a maid executed for leaving a fruit stem on the floor. However, he was a skillful general and ruler who successfully exploited the forces of the day to

his advantage. He was a leader among Japanese daimyo in adapting firearms to his army and using them to great effect. He also built his economy by building roads, abolishing tolls, and establishing open markets and a standard coinage. One other thing Nobunaga did was favor the Christians against the militant Buddhist monasteries that he especially disliked. Success bred success for Nobunaga, since each victory attracted more followers to his standard, which led to more victories and so on. By his death in 1582, Nobunaga controlled 32 of Japan's 66 provinces. It was left to his successor, Toyotomi Hideyoshi, to nearly complete Japan's unification.

Hideyoshi was originally a peasant who had risen through the ranks to become one of Nobunaga's most trusted generals. Like Nobunaga, he was also a superior general, being both bold and resolute in action. Although not quite as cruel as his predecessor, he could still be ruthless as he avenged Nobunaga's death, eliminated any rival generals who might make a bid for power, and got Nobunaga's lands under his control. By 1590, Hideyoshi had unified all of Japan except for the lands of Ieyasu Tokugawa with whom he concluded a treaty that lasted until Hideyoshi's death in 1598. Hideyoshi declined to assume the title of shogun since he was not related by blood to the current line of shoguns.

Once Hideyoshi's power was established, he followed three policies that would profoundly affect Japan's future course of development. For one thing, he launched two invasions of Korea (1592 and 1597). Both of these failed, largely due to the Korean navy of armored "turtle" ships that cut the Japanese army in Korea off from its homeland and forced its retreat. Despite these defeats, one can see this as part of a greater expansion of the Japanese people, going along with the spread of Japanese settlers, mercenaries, and pirates (wako) throughout East and Southeast Asia.

Secondly, despite his own peasant origins, Hideyoshi cracked down on society in an attempt to stifle the social mobility that had helped stir up so much turmoil over the past century. In an attempt to disarm the populace, Hideyoshi launched the Sword Hunt, confiscating all weapons, especially firearms, from non-nobles under the pretext of melting them down to make a statue of Buddha. He

also prevented peasants, merchants, and samurai from changing their professions or switching overlords, thus creating a rigid social structure that lasted until the mid 1800's.

Hideyoshi's third policy concerned growing tensions with European Christians, whose ability to trade with China had greatly increased their influence in Japan. As we have seen, the Japanese liked the Jesuits whose self-discipline and habit of preaching mainly to the upper classes did little to disrupt the harmony of Japanese society. However, several things about Christianity disturbed many Japanese: their meat diet (since the Japanese were mainly vegetarian), their intolerance of other religions, their slave trade which took Japanese out of their country, and the question of who Japanese Christians were more loyal to, their own rulers or the Christian God. In 1587, after one of his vassals refused to renounce Christianity, Hideyoshi decreed all Christian missionaries should leave the country. However, the decree was not strictly enforced, and missionaries just kept a low profile as they did their work. Tensions increased in 1593 with the arrival of Spanish Franciscans who raised suspicions of trying to stir up rebellion by focusing their preaching on the lower classes. A dispute over ownership of a Spanish galleon shipwrecked off the coast of Japan in 1596 led to fears of a Spanish invasion and persecution of Japanese Christians.

Hideyoshi's death in 1598 led to a power struggle which ended with the new ruler, Ieyasu Tokugawa, establishing his power and even assuming the title of shogun. During this time, problems with the Christians were put on hold. However, in 1600, Dutch Protestants arrived who told stories about their Spanish enemies that revived Japanese fears of all foreigners. As a result, Tokugawa outlawed and persecuted Christians. His successors went even further, banning virtually all foreigners from Japan by 1639. Only two Dutch ships and a handful of Chinese and Korean ships could enter Japan each year to trade. For the next two centuries, Japan would cut itself off from the rest of the world and develop on its own.

Growing Problems under the Ashikaga Shogunate

A Wako (Japanese pirate) raid is met by Chinese Ming forces (c.1600). Largely because of such raids China also cut off most of its contact with the outside world.

***The Ashikaga Shogunate* is also known as the Muromachi era after the district of Kyoto holding government headquarters. Just like its successor, the Tokugawas, this dynasty produced fifteen shoguns. Several inherent weaknesses plagued the Ashikagas. For one thing, they owned very little land, compared to the Tokugawas who would own one quarter of Japan's land, most of its mines, and nearly all the important towns. Also, unlike the Tokugawas, The Ashikagas had a small army of only about 350 men, forcing them to rely on alliances with other houses. In addition, they faced the dilemma of either strengthening their shugos (governors), who weren't necessarily good or loyal, thus making them a threat to the central government, or keeping them weak and thereby ruining the shogunate's power.**

The Ashikagas tried to keep the nobles under control by requiring them to live at court, either in Kyoto or Kamakura, making it treason to leave without permission. These hostages brought plenty of followers, one family supplying 3000 such workers, which did supply free labor for the dynasty's building projects. The nobles' virtual captivity at court also led to a gradual fusion of the samurai with the civilian court nobles, something that would help the development of a national culture. On the other hand, so many nobles at court could also influence policy.

***The Onin War (1467-77)* over the shogun's successor, saw the imperial capital, Heian-kyo, become a battleground with the streets littered with corpses and cartloads of severed heads**

collected as trophies. It also saw warfare changing from being ruled totally by the samurai to the growing use of peasants, called *ashigaru*. At this time daimyo started relying more on strategy instead of individual duels, organizing their ashigaru into tightly packed formations of pikemen. As a result, even low ranking soldiers could distinguish themselves at the expense of the samurai, since there was no strong central power to stop their upward mobility.

***Wako*, from the Chinese word for dwarves (for their small ships?), were Japanese pirates who disrupted trade throughout East and South-east Asia. Although Japanese in origin, many, if not most, were non-Japanese. Years of peace in Japan led many restless warriors to join their raids as well. Some raids had 100's of ships and penetrated 150 miles inland.**

Top: Japanese wako disembark for a raid on the Korean coast in the late 1300s.

Bottom: A model of an attack by wako ships on a Korean trade vessel

Since many daimyo were providing wako protection and supplies in return for part of the loot, the Ming dynasty cut off trade with Japan and built a fleet to combat their raids. In response, the wako often turned to trading illegally for Chinese goods. However, this didn't satisfy Japan's hunger for Chinese goods, especially silk, thus leaving the door open for the Portuguese, who could trade with China, to enter Japan.

Like the Vikings in Europe, many wako settled down in areas they raided: the Philippines, Thailand, Java, Malacca Strait, Indonesia, and Indo-China. Once settled, they used a

combination of warfare, peaceful trade, and meddling in local politics to enhance their own influence.

Japanese castles. Much like in feudal Europe, Japanese warlords built castles to secure their independence. While these structures were every bit as impressive as their European counterparts in terms of military engineering, they were also aesthetically pleasing as works of architecture.

Himeji Castle (below), known as the White Heron for its appearance, is the best preserved of Japan's feudal castles. Although originally built in the 1300s, it was built in its present form by Hideyoshi Toyotomi and Tokugawa Iyasu's son-in-law between 1581 and 1601.

The overall complex of Himeji Castle (below) had 83 buildings, such as storehouses, gates, corridors, and turrets and a circumference of 2.53 miles. The highest walls of the castle are 85 feet (26 meters) tall, while the castle keep reaches a height of 152 feet (46.4 meters). It was also coated with white plaster to resist fire. Like European castles, it was built with over 1,000 loopholes for archers and musketeers, as well as "stone drop windows", angled chutes for dropping stones or boiling oil.

Bottom: A map of the overall complex of Himeji Castle with the surrounding city shows how its moats offered yet another defense layer against attackers.

Zen Koans

Since Zen taught that our ordinary rational thinking creates barriers to our seeing the unity of the universe around us, some Zen masters would try to "derail" their logical thinking by creating illogical paradoxes and riddles known as koans.

For example, a group of Zen masters would have a great time declaring that there is no such thing as Buddhism or enlightenment or anything even remotely resembling Nirvana and would set traps for one another to get them to say that such things exist. Similarly, a novice who made a respectful allusion to the Buddha would be ordered to rinse his mouth out and never utter that dirty word again. In another case, whenever he was asked the meaning of Zen, an ancient master would raise one of his fingers. Another would kick a ball, while another would slap the inquirer in the face.

One famous story involved a monk who approached a master asking him for instruction. The master asked if the monk had eaten breakfast yet. When told yes, he told him to go wash his bowl. From this the monk was enlightened as to the meaning of Zen. Below are some of the better-known koans.

- A cow passes by a window. Its head, horns, and the four legs pass by. Why did not the tail pass by?"
- What was the appearance of your face before your ancestors were born?
- What is the sound of one hand clapping?
- Tang government officer: "A long time ago a man kept a goose in a bottle. It grew larger and larger until it could not get out of the bottle any more. He did not want to break the bottle, nor hurt the goose; how would you get it out?"

Master: "O Officer!"

Officer: "Yes"

Master: "There, it's out"

- **Question:** What is the meaning of Bodhidharma coming from the West?
Answer: The cypress tree in the garden.

And now my favorite Zen story:

One day, the Japanese Zen master Tanzan and a monk came across a beautiful woman unable to cross a stream. Tanzan immediately picked her up and carried her across. Some time later, as the two men were walking, the monk finally asked Tanzan how he could touch a woman and hope to maintain his purity. To which Tanzan replied: “I put her down long ago, while you are still carrying her.”

Tea Ceremony, Flower Arranging, and Rock Gardens

An example of a tea ceremony house

The tea ceremony, imported from China, was another Zen ritual. It emphasized simplicity in nature, taking place in a thatched hut with a small simple room to “foster the spirit of harmony, reverence, purity, and tranquility”. It was originally performed by samurai to honor a friend, and many of the postures and how the host holds the instruments reflect those origins. By the same token, everything about the ceremony is incredibly precise and demands being totally focused and disciplined.

The tea ceremony involved only a few guests and took several hours, leaving time for discussion, usually about something like the host’s art objects.

“Chanoyu, the Japanese tea ceremony, celebrates imperfection and variety. No two objects are ever the same. Every artifact used for the ceremony is noticed and appreciated...Do not fill the entire bowl with tea, but rather leave most of the interior to be admired while drinking.

Notice how the warm tea bowl feels in your hands. Is the surface rough, or smooth? How does the bright green tea look against the black or pink glaze? “--an ad for tea ceremony bowls I thought expressed the spirit of their simple elegance.

Ikebana, Japanese flower arranging, also fits in well with Zen, stressing the simple and understated arrangement of flowers over a full bouquet. Like Taoist art, empty space serves to accentuate everything else. Each ikebana arrangement is a world of its own, creating a simple and natural harmony between the vase, stems, and flowers in an effort to create a bit of nature in its irregular purity. In ikebana quality is preferred over quantity, asymmetry over symmetry, flower buds over full-blown flowers. Even a single branch in a vase counts as a total ikebana arrangement.

Zen rock gardens. As with the tea ceremony and ikebana, zen rock gardens strive for an asymmetrical simplicity that evokes a calm peaceful sea (represented by white sand or rocks) and rock “islands” scattered about in a seemingly random way.

Oda Nobunaga and the New Warfare

Not a man to be trifled with. When Nobunaga captured a man who had shot at him many years earlier, he buried him up to his head and sawed it off. In a similar vein, he had some enemies publicly bound, leaving a bamboo saw for passersby to take one or two swipes, slowly torturing his victims to death. Nobunaga especially hated Buddhist monks, once burning 150 of them for performing funeral services for a departed clan head. Not surprisingly, the monks reciprocated Nobunaga's hostility. It would take Oda 11 years to break the power of one especially intransigent group of warrior monks known as Ikko-ikki.

Besides waging war, Oda Nobunaga also encouraged merchants and trade with open markets, making them tax exempt, abolishing tolls and forced labor, and curbing the guilds' monopolies. He encouraged the building of ships and roads, tried to set up a standard coinage, and favored contact with the outside world through Christian missionaries. Below: a model of a Japanese town from this period

The new warfare. Firearms first entered Japan in 1542 by way of Portuguese merchants. Within six months, the ever-inventive Japanese were making their own guns and improving upon them, notably adding a covering to keep a muskets and its charge of powder dry, so it could even be fired when it was raining.

Since reloading early firearms took so long, the Japanese, as in Europe, created blocks of pikemen to guard the musketeers between volleys. This further enhanced the status of peasants needed to fill the ranks of these armies, an issue Hideyoshi Toyotomi would deal with later.

As with any new technology, it took a while to adapt old behaviors to muskets. Early musket training incorporated the highly formalized and rigid postures and motions that samurai used in hand-to-hand combat. Eventually, they realized the uselessness of this for muskets and adapted a more efficient drill. However, samurai continued to announce their lineage before combat, while the lowborn *ashigaru* on the other side would just shoot them.

Oda Nobunaga was the first daimyo to use firearms as an integral part of his army. At the battle of Nagashino in 1575, his 3,000 arquebusiers (musketeers) blunted the charge of the Takeda samurai cavalry, leaving them open to a counterattack by his own samurai.

Japanese castles, much as in medieval Europe, had evolved from wooden stockades to highly complex centers of power that could tie down besieging armies and fleets of ironclad gunships for years. For example, Osaka castle, the final stronghold of the Ikko-ikki, had a complex of 51 fortified outposts. It took four years for Oda Nobunaga to reduce this huge fortress. When it finally surrendered, with uncharacteristic generosity, he let the surviving defenders go.

Years later, Oda's successor, Toyotomi Hideyoshi, would build the present castle, Japan's largest, on the site of the old one.

In 1560 Oda faced his first big test when a powerful neighbor, Imagawa, led 25,000 men through his province of Owari on his way to attack Kyoto. Nobunaga ambushed Imagawa with only 3000 men in a narrow defile during a blinding rain. This triggered a stampede and the beheading of Imagawa by one of his own officers, Tokugawa Ieyasu. This also led to a rush of independent samurai to Oda's standard.

Nobunaga's death. Mitsuhide, a former enemy, had come over to Nobunaga's side. During a siege conducted as Nobunaga's ally, Mitsuhide had sent his mother to the enemy fortress as a hostage to get them to come out and negotiate surrender. However, when they came out, Nobunaga crucified them. Naturally, Mitsuhide's mother was killed in revenge, which embittered her son. Some time later, Mitsuhide betrayed Nobunaga and marched against him instead of for him at a critical moment. Nobunaga was taken off guard and trapped in a temple where he committed suicide.

The Meeting of Cultures

The Jesuits landing in Japan

Through European eyes: Jesuit views of the Japanese. In 1549, seven years after the first Portuguese landing, Jesuit missionaries arrived in Japan and made several astute observations about their hosts. They found them soft spoken and friendlier than the haughty Chinese and admired their reverence for dead ancestors and table manners, which they learned the importance of at all levels. They admired the simplicity and elegance of the tea ceremony and were amazed at the Japanese cleanliness and skillful use of chopsticks.

The Jesuits were struck by the lengths to which the Japanese went to save face and avoid combat

through an elaborate system using third parties to negotiate between spouses, fathers and sons, and masters and servants. On the other hand, they saw the samurai as combative and holding too high an opinion of themselves. They were also shocked by the Japanese habit of bathing in full view of the street.

To the Japanese, the European habits of eating with the hands and wiping the mouth with napkins seemed gross. Both cultures found the other's music dissonant.

The Japanese liked the Jesuits for their discipline and noble bearing, their practice of focusing on converting the upper classes, and ability to trade with China. Therefore, Daimyo often converted for trade and recanted when it didn't arrive.

Many Japanese converts probably confused Christianity with Amida Buddhism, since both have prayer beads and believe in redemption. Another thing they either failed to grasp or accept was Christianity's exclusive nature. This would put Christian samurai in the difficult spot of having to choose between loyalty to Japan or the Church, which in turn would lead to the expulsion of all foreigners from Japan. However, the lack of a central government at this time prevented totally getting rid of Christian missionaries, even if the daimyo wanted to.

Nagasaki, with its deep-water harbor was even given to the Jesuits to facilitate trade with China. A board of Jesuits collected harbor dues and split them with the local daimyo. It rapidly became very Christian, with schools, churches, and a fortified Jesuit headquarters.

During World War II, Nagasaki's strong association with Christianity led to the belief it was immune to American bombing raids, and indeed it did escape major destruction through most of the war. Unfortunately, being relatively intact marked it as a secondary target for demonstrating the power of the atomic bomb. Therefore, on August 9, 1945, when clouds obscured the primary target, Kokura, Nagasaki became the second (and so far the last) city to suffer a nuclear attack.

Turtle Ships and Karate

Hideyoshi Toyotomi was originally a peasant who entered Nobunaga's service as a sandal holder, and from there rose through the ranks to become one of his most trusted generals. Despite his humble origins, he was hardly sympathetic to the lower classes, tying the peasants to the soil and encouraging daimyo to enforce rigid codes to keep them in place.

Hideyoshi was less cruel than Nobunaga, but not by much. For instance, having adopted his nephew as his heir, he forced him to commit suicide when his own son was born, then put his nephew's wife, three young children, mistresses, and servants to the sword, dumping their bodies in a pit he called the animal mound.

Another time, when he came across some abusive graffiti, Hideyoshi seized eight townsmen, cut off their noses one day, their ears the next, and strung them upside down and had them impaled on the third day.

Hideyoshi was appointed regent in 1585 and chancellor in 1586. However, he did not take the office of shogun, since only descendants of the Minamoto clan customarily held that title.

Korean "turtle ships." One element in defeating the first Japanese invasion was the fleet of Korean "Turtle ships", armored vessels that could ram an enemy or blow it apart with their artillery and incendiary devices similar to Greek fire. The term turtle ship comes from the top of the hull, which was covered with iron and spikes to protect it from enemy fire and boarding efforts.

The role of these ships in defeating the Japanese invasions has been exaggerated, since only three were built due to a shortage of iron. However, the use of firepower by other all-wood Korean ships probably was important.

While his Great Sword Hunt was supposed to be for making a statue of Buddha, it was used instead to make a statue of Hideyoshi.

Karate. Hideyoshi's disarming of the common people led to the martial arts discipline known as karate, which literally means "open hand", referring to the ability of an unarmed man to defeat an armed one.

The 26 Martyrs of Japan. In 1597, as part of Hideyoshi's crackdown on Christianity, authorities arrested and crucified 6 Franciscan missionaries and 20 converts. This drove the remaining Christians underground. Surprisingly, a community of Christians survived the Tokugawa shogunate until Japan opened up to the West 250 years later.

Tokugawa Japan (c.1600-1867)

A folding screen painting of Sekigahara (1600), the decisive battle in Tokugawa Ieyasu's final unification of Japan

Concerning the unification of Japan, it was said that Oda Nobunaga kneaded the bread, Hideyoshi baked it, and Tokugawa Ieyasu ate it. His final step in the reunification of Japan came in 1615 with the taking of the powerful castle of Osaka. Supposedly Tokugawa took the castle by convincing its owner to dismantle part of its defenses in return for him leaving. He left, then came back to take the weakened fortress. With this final piece of the puzzle in place, Japan was unified at last.

The final exclusion decree. It was the shogun Tokugawa Iemitsu (1623-51), Tokugawa Ieyasu's son, who issued the final exclusion decree in 1639 that cut Japan off from the outside world for over 200 years except for one Dutch and one Chinese ship per year.

Tokugawa Iemitsu also instituted the *Sankin Kotai* system where daimyo had to spend half their time living at the court at Edo (modern Tokyo) while leaving their wives and children as virtual hostages there.

The era of Japanese history under Tokugawa rule is known as the Edo period, after the original name for the Tokugawa capital, Tokyo. Although politically isolated, Japan at this time showed great vibrancy, both economically and artistically, thus preparing it for modernization in the 1800s.

One of the most famous artists of the Tokugawa era was Hiroshige, whose paintings of common people, such as those crossing a bridge here, reflected changing social mores despite the strict legal dominance held by the samurai

Early Kabuki drama started in the early Tokugawa period as song-and-dance numbers done by troupes of female dancers. However, such dances being done by women was seen as lewd, so female dancers were banned from performing. Only when men replaced the women, including taking female roles, did Kabuki gain more respectability and legal status.

The "Floating World". Although rich, the middle class during the Tokugawa era were still looked down on in the classic Chinese sense as leeches who lived off others' labors. As a result, sumptuary laws forced them to be circumspect about displaying their wealth. This resulted in the thriving subculture known as the "floating world", named after the nightclubs on houseboats. To comply with sumptuary laws, middle class would wear reversible coats, with plain exteriors in public and the more sumptuous ones in the clubs.

Japanese woodblock printing Although woodblock printing had been used in China for centuries, it was only during the Edo (Tokugawa) period that it was widely used for copying books and paintings. Since it was so much faster than hand copying, books could be printed much more cheaply, thus dramatically increasing literacy among the Japanese population, a crucial factor in Japan's rapid industrialization after 1867.

Woodblock printing also proved an effective way to popularize art in Japan. Unlike the oil-based inks used in Europe, Japanese printers used water-based inks, which gave them a wide range of colors.

Probably the most famous woodblock print was this painting, “The Great Wave of Kanagawa” from Hokusai’s “53 Views of Mt. Fuji.” As the name implies, it consisted of 53 views of Japan’s most famous mountain. Sometimes Mt. Fuji takes center stage, while at others it forms the backdrop for various scenes of Japanese life: fishermen, ferrymen, woodworkers, villages, placid lakes, and giant waves.

A model of the Tyogoku Bridge leading to Edo (modern Tokyo) in the early 1800s, showing Japan’s thriving economy under the Tokugawas.

9.4 The Secret History of Monsters: An Historical Parody

Foreword. As a teacher, I've always put a premium on keeping students interested in and even entertained by history. Therefore, I've developed a parody of history based on the idea that giant prehistoric monsters that (for some mysterious reason) always attack Tokyo are real, having their own history and culture. If this is your cup of tea, please enjoy this in the spirit of believing life is too short not to have a good laugh and that nothing should be taken too seriously. Even Zen monks know that. If this isn't your cup of tea, I'm not forcing you to read it. You've been forewarned and should probably delete this foreword for the more sensitive children in your class. (By the way, I only drink tea that is cold and from a bottle.)

Introduction. The recent release of "Pacific Rim" has generated a lot of interest in monster attacks on Humanoid cities. Just where did these monsters come from? What do they want from us? Why do they only keep attacking Tokyo? These are just some of the questions this short essay will hopefully answer about these mysterious creatures who both terrorize and fascinate us.

Geographic factors. First of all, geography plays a major role in explaining monster history, which has centered on Japan, a Godzilla word meaning "Monster Island." For one thing, Japan used to have lots of active volcanoes, which are perfect for hatching monster eggs. Unfortunately, most of these volcanoes got stopped up by particularly large eggs and went extinct one by one. Since then monsters have moved their reproductive activities to another, undisclosed, location also referred to as Monster Island, a fact that creates a lot of confusion.

Besides volcanoes, Japan also had a warm climate and plentiful supplies of zinc, a mineral crucial for giving monsters shiny coats with which to attract mates. As a result, the period c.6000-5000 BCE saw a dramatic rise in the monster population, with frisky young monsters digging up more zinc during each 500-year reproductive cycle, causing more baby monsters, and so on until Japan's zinc deposits were exhausted.

Finally, the staple of any monster's diet is fish (Humanoids tasting awful to them), and the Sea of Japan has (or used to have) lots of fish. While this would lead to later troubles with the Humanoids, this plentiful supply of fish along with the other factors mentioned above, led to what is seen as the Golden Age of the Godzillas, lasting from 4200 to 2350 BCE.

Social structure of Monster Island. While there are many different classes of monsters organized into a strict social structure, they break down into four main castes, five if one includes the bottom rung of Humanoids. The ruling caste is that of the Godzillas (Japanese *Gojiras*), from which their empire gets its name. As a result, monsters of all kinds are often mistakenly referred to as Godzillas, a faux pas that real Godzillas take particular exception to. True Godzillas, which means "friendly dragons", rule by right of having the highest IQ, averaging 165, and the sole ability to breathe radioactive fire.

Next came the Titantosaurs, who were physically distinguished from Godzillas by being generally quadrupedal and not being able to breathe fire. With an IQ of 135, they served as civil servants. Below them were the Rodans, who bore an uncanny resemblance to prehistoric pteranydons. Only having an average IQ of 120, for which they were sometimes derisively called Newmans, they were in charge of the postal service.

Subject to even more ridicule were the Mothras, who, as their name implies, looked like giant moths. Considered too stupid and emotionally unstable for anything else, they were given light "messenger duties" that usually consisted of taking giant rocks to other cities. Even when given such simple tasks, they were prone to fly off course, often reaching the Arctic where their wings would ice up, causing disastrous crashes. This explains both the sparse present-day population of Mothras and equally sparse Humanoid population at the North Pole.

At the bottom of the heap were the Humanoids, who, because of their tiny hands that could wield hammers and screwdrivers, were used for

construction projects, especially temples to the Holy Mackerel and other deities in the fish pantheon.

Things prospered peacefully until humanoids of the “Third planet escaping from the Black Hole” attacked earth using giant Mechagodzillas. Godzillas led the fight to drive out the Mechagodzillas by swinging them around by their tails and launching them back into outer space. Unfortunately, only an estimated seventeen Godzillas survived.

Following this came the “Time of Troubles” (2350-1498 BCE) when humanoid revolts drove the monsters into the sea, triggering in turn “The Big Sleep” (1498 BCE-1945 CE) during which the monsters lay dormant, licked their wounds, and only woke up every 500 years to dutifully reproduce.

This might have been the end of their sad story, except for reckless Humanoid activity during the Industrial Revolution culminating with a string of nuclear tests near Monster Island in the 1950s.

Thus began the Age of the Big Stomp (1954-61) when monsters, mainly Godzillas, would wake from their lethargy and stomp Tokyo with “fire and tail” to promote global environmental awareness. Eventually, the Humanoids would claim they had learned their lessons. The monsters, being satisfied, would go back to sleep, only tempting the Humanoids to go back to their old tricks and start the cycle over again. This pattern repeated itself three more times: in 1956, 1957, and 1961.

One of the most remarkable phenomena to emerge from these attacks has been the incredible resilience of the Japanese people and their ability to rebuild Tokyo practically overnight, only to be forced to do it a few years later. The key to this has been the pre-fab construction industry developed in nearby Osaka. How they developed this so quickly is still a mystery, although rumors abound that the Godzillas, feeling guilty for all the damage to Tokyo, gave the technology to the Japanese, who quickly adapted it for making cars.

Along similar lines, anime, previously considered an artistic creation by the Japanese, also owes its origins to Godzilla art. (Notice I use the term “Godzilla” here, because they are the only class of monsters capable of such remarkable innovations.

The Fourth Battle of Tokyo in 1961 was the last official battle between the monsters and Humanoids. The turning point came later that year when a team of intrepid scientists doing research on Monster Island saved a baby Godzilla from the Spiga (giant spider). (Footage of this served as the basis for “The Son of Godzilla”, the only monster film that faithfully followed the historical facts.) The Godzillas, grateful to the scientists for saving their *miny*a (a term used to describe baby Godzillas that can only blow smoke rings, but not fire) made peace with the Humanoids in December 1961, a treaty that has *officially* held up ever since.

Unfortunately, the Time of Troubles had disrupted the orderliness of monster society, and a number of roninzas (rogue monsters) attacked Tokyo between 1962 and 1974. In each case, the Humanoids called for protection from the Godzillas, who honored the mutual defense pact with the Humanoids and defeated the monsters, although Tokyo was effectively destroyed each time in the process.

The first major disruption came in 1962, when a rodan attacked Tokyo, blowing it away with the gale force winds generated by its giant flapping wings. Fortunately, a Godzilla came to the rescue, blinding the rodan with his fiery radioactive breath, causing him to crash to his death on Mt. Fuji. (There is still an obscure museum on Mt. Fuji displaying fragments of the rodan’s wings.)

Two years later there was an attack by two Pupaesauruses (baby Mothras) who destroyed much of Tokyo by spinning a giant web around it and crushing it. Although a Godzilla came to fight them off, it was really the efforts of two tiny women (both of whom could fit in the palm of your hand) who emerged miraculously when one of the Pupaesauruses hatched into a full-blown Mothra. The two tiny little women sang a hauntingly beautiful song that convinced the Mothra to crash to

its death on Mt. Fuji. Meanwhile, the Godzilla squished the other Pupaesaurus with his giant foot.

In 1974, the last rogue attack on Tokyo took place when a Titantosaur allied with a visiting Mechagodzilla and attacked Tokyo. This time, technology came into play as Japanese scientists developed a sonic ray that emitted a frequency that disrupted the Titantosaur's inner ear, making him fall over like a bridge.

Some historians claim this was technology adapted from a similar sonic ray developed against an attack by giant grasshoppers in Illinois in the 1950s. In this case the device mimicked the mating call of grasshoppers that by that point controlled Chicago, and lured them to a watery grave in Lake Michigan. The jury is still out about the possible link between the two technologies, fracture lines between historians pretty much following nationalist lines.

Meanwhile, the Godzilla, after an epic battle, took a lesson from ancient history, grabbed the Mechagodzilla by the tail and flung him back to the "Third planet escaping from the Black Hole". No Mechagodzilla sightings have been reported ever since.

This marked the end of rogue monster attacks on Tokyo, although there was a sad epitaph to the whole tale. Apparently, scientists in Osaka, exhausted from constantly rebuilding Tokyo, developed a powerful ray that, when fired at a tiny full-scale replica of the city, would enlarge it to life size. Regrettably, their calculations were off and the Tokyo they created was three times larger than the original one, thus making it impossible for normal Humanoids to live there. As a result, a team of Godzillas was called in to level the oversized Tokyo with fire and tail so that the city could be rebuilt from scratch. This unfortunate incident, of course, is the basis for the current international ban on enlarging rays.

While 1974 marked the end of the rogue monster attacks on Tokyo, its problems weren't over yet. The truth is that adult monsters are generally benign, although a bit cranky when disturbed by such things as atomic tests going off in their living

rooms during their favorite reruns of the 1950s sitcom, "I Love Lucy." In fact, the recent spate of Godzilla attacks starting in 1998 are closely related to the monsters' 500-year reproductive cycle, at the start of which female monsters go into heat (i.e., volcanoes) where they lay their eggs, which hatch after a gestation of 50 years.

Around age 1,200 years the monsters reach adolescence and go through a very wild and virtually uncontrollable phase, made no easier by the fact that monster parents are very lenient and let their kids do whatever they want as long as it doesn't interrupt their watching Lucy's hare-brained schemes. (Some monster child psychologists theorize that the plots of "I Love Lucy" are the direct inspiration for the resulting teenage pranks.

Luckily for the Humanoids, the little scamps confine their antics to one night a year, Halloween, when the Humanoids are least likely to notice anything is amiss. (These festivities used to take place on Flag Day, but drew too much attention and adverse publicity, and so were moved to October 31st.)

Fortunately, most Monster Mashs aren't very destructive and provide little or no usable footage for Hollywood movies. After the Age of the Big Stomp and rash of rogue attacks ending in 1974, things settled down after monster legislation outlawed underage inhalation of sulfurous volcano fumes, which make monsters under the age of 2,100 especially rowdy.

Since then, the only two really destructive Monster Mashs have taken place in 1998 and 2012, both being years that the mischievous little smoke ring blowers found a heretofore undiscovered volcano and smoked themselves into a sulfurous city-bashing high. In fact, they were so schnoekered in 1998 that they missed Tokyo altogether and destroyed Kyoto, the only example of a city besides Tokyo (a Godzilla word meaning "Party Central") being the scene of a Monster Mash. Footage from the most recent outbreak in 2012 became the basis for "Pacific Rim."

Of course, Hollywood always has to tamper with historical events, vainly hoping to make them more exciting. Therefore, they superimposed computerized images of people in robot suits fighting, and unbelievably, beating the monsters. Except for ignoring every law of physics that dictates how impossible such robots would be, this idea of humanoids defeating the monsters was nothing new, and it did alleviate public fears about reported monster attacks on Halloween, something the authorities could usually explain away as drug-induced hallucinations or swamp gas.

One major discrepancy between earlier Godzilla movies and “Pacific Rim” was the form that the monsters took, which traditionally would look either like giant dinosaurs or moths. However, over the years, this annual event has developed into an elaborate costume contest, where the monster whose costume is deemed the funniest parody of a human superhero wins an all-inclusive dream vacation inside Mt. St. Helens. Seeing this as a golden opportunity, cutting edge fashion designers came up with a whole new generation of Humanoid superhero costumes that pushed the Monster Mash costume contests to Carnival-like proportions.

This explains the truly bizarre and (from the monsters’ point of view) hilarious appearance of the monsters in “Pacific Rim”. This should also dispel any rumors that the monsters seen in that movie were just fake special effects.

Monster Religions

As intelligent as monsters, in particular Godzillas, are, it might seem strange that they worship something as primitive as fish. Some historians think this appeals to their strong sense of tradition, while others see it as a way for the Godzillas to keep the lower classes in line. However, considering that even a baby Godzilla eats 25,000 fish each day, it is no wonder that at

some early date the monsters took to worshipping fish.

Like the Christian Church, the Giant Fish Religion, known as Salmonism, had its own reformation in reaction to priestly corruption. Triggering it was the selling of frozen fish sticks as a guarantee of time out of purgatory, which monsters imagine as a giant ocean full of fresh water. After this, there were three main splinter groups breaking off from Salmonism: Our Lady of the Divine Trout, the Holy Mackerel, and the Fellowship of the Sacred Halibut. For these believers, the Salmon is still the true Fish Head, while other types of fish represent its various avatars. As the ad below indicates, there are strong efforts to reunite the various sects into one school of belief.

The lowest class in the monster hierarchy, Humanoids, has never taken to worshipping the Giant Fish God in any of its incarnations. This may have to do with all the forced labor spent on building pagodas (literally: fish houses) for the monsters. However, there was a short-lived Humanoid cult in the early 1960s that worshipped Mothras and the two tiny little girls who could summon them with their song. Below: a picture showing how tiny they were:

This heresy abruptly collapsed in 1964 when a Mothra attacking Tokyo inexplicably crashed into Mt. Fuji and shattered into a million pieces. The tiny little priestesses reportedly found

employment in a carnival sideshow where they made a fortune, eventually retiring to a small town somewhere in Arkansas.

Godzilla Fun Facts

Godzillas love to dance, especially clogging.

Godzillas are very family oriented and attend church regularly, politely waiting until the service is over before wrecking the church.

The Godzilla education system has historically been ranked as the world's finest. Japanese humanoid schools strive to carry on this tradition.

Victoria's Secret has recently marketed a line of miracle bras for female Godzillas, called Brazillas.

Godzillas' favorite music is Tibetan throat singing.

Despite their noted intelligence, in a rare lapse of judgment, the Godzillas were initially taken in by the Mechagodzillas' deceptively friendly

demeanor, leading them to reveal the launch codes for their ICBMs.

Arguably the greatest chess game in history took place when a Godzilla challenged a Mechagodzilla to a game of chess. The Mechagodzilla resigned after 63 moves (over a period of 21 years), seeing a forced checkmate in seven moves (and with only 4 years left on his clock).

Lesser-Known Monsters

Guiron. Considered the most reclusive of monsters, little is known of Guirons except that they make terrible dinner guests.

While everyone is familiar with Godzilla, Rodans, and Mothras, there are less well-known monsters that deserve some discussion. Following is a short but by no means comprehensive, list.

Gamera. This illustration of “Flaming Monster Gamera” (from *An Anatomical Guide to Monsters*) reveals eyes that can see in the dark, arms strong enough to lift and throw a 50-ton boat, and “fire sacks” that let Gamera shoot flames from his hands. The illustration also shows a series of sack-like organs for storing lava, oil, coal and uranium (like Godzilla), as well as balloon-like organs in the legs that can blast air through the bottoms of the feet, allowing it to fly like a jet. Despite their similar appearance to turtles, gameras can fly at speeds comparable to that of rodans (mach 1.5)

Jiger. According to this anatomical drawing, Jiger has a pair of horns that can shoot missiles made of hardened saliva and another one that fires a deadly magnetium (?) beam. Other characteristics of Jiger include extremely powerful suction cups covering the entire body, an organ that enables Jiger to spit jets of seawater at 300 kilometers per hour, a stomach that can melt iron ore, and a tail that functions as an ovipositor (whatever that is).

The main function of Jigers is supposedly as auto mechanics. Although no one has ever seen a Godzilla car, they reportedly get mileage comparable to a Toyota Prius (when the accelerator is working properly).

Pupaesaurus (Mothra larva). This anatomical sketch of Mothra in larval form shows a robust

jaw, an enormous stomach, an elongated silk-producing organ, a row of breathing orifices on either side of the body, countless cilia on the bottom surface, and a rudimentary nervous system consisting of a cerebral ganglion and a network of nerve ganglia distributed across the body. Mothras used to be kept in insane asylums, but more enlightened views now prevail, so they are given supposedly “harmless” tasks like dropping boulders in the sea. But even this can backfire, as seen with the Fiji disaster of 2008. Efforts are still under way to figure out how to convert their tremendous silk producing abilities into commercial profits. The main problem has to do with the fact that the silk thread is 10 feet in diameter, weighs 700 pounds per linear foot, and is impermeable to any cutting technology we currently have.

Angirus. As seen here, Angirus (who belongs to the Tiatantosaurus caste) has eyes that can detect infrared light for scanning immigration documents, highly developed rear leg muscles, a heavily spiked rear carapace for romance, and an extra pair of sub-brains to control the forelegs and rear legs, which makes him highly prone to Restless Leg Syndrome when playing chess.

Godzilla Humor

A Godzilla tricks a giant ape with the old hand buzzer trick. The ape got the last laugh however, because giant apes don't even exist

Godzillas have what may be the most highly developed sense of humor in the galaxy. Not surprisingly, their jokes center on the stupidity of Mothras and Humanoids. Their favorite TV shows are "I Love Lucy" and "Seinfeld", although nearly anything that Humanoids or Mothras do will send them into fits of laughter. A growing number of scientists believe that all the attacks on Tokyo were done either as big jokes or on a drunken dare. Think about it, what could be funnier than all those tiny humanoids scurrying around to rebuild Tokyo, knowing it'll be destroyed again in a couple of years? Why don't they all just move to Osaka?

Mothras take their lumps in the humor department as well. Below: When the teacher points out how Japan looks like a Pupaesaurus, everyone in class has a good chuckle...everyone that is except for the Pupaesaurus.

Here we see a Mothra flying out of a party in a rage after a Rodan put DDT in her Pepsi. Mothras, the constant butt of such party jokes,

are hypersensitive about their subhuman intelligence.

A few choice Godzilla jokes:

Q: What's smaller than a human?

A: A Mothra's brain.

Q: How many Mothras does it take to change a light bulb?

A: One, but only after she's broken 10,000 trying to fly into the light.

Q: How many Humanoids does it take to change a light bulb?

A: One, but it takes 1,000 of them to run the factory that makes light bulbs.

Godzillas even think surprise parties are hilarious. Above we see Godzilla and Pupaesaurus springing a surprise party on Gidra for his 4,000th birthday, although Gidra still jokes that he's only 3,999.

[Back to flowchart](#)

THE RISE OF THE ITALIAN CITY-STATES (c.800-1200)

The first stirrings of revival from the Early Middle Ages in Western Europe took place in Italy. There were three reasons for this. First of all, the Roman cities were older and more deeply rooted than cities in Northern Europe. Second, their position in the middle of the Mediterranean attracted trade from the richer Byzantine and Muslim civilizations in the East. Finally, the Byzantine Empire, which ruled parts of Italy, protected its towns there from at least some of the chaos of the times. Italian towns were much reduced in size from the days of the Roman Empire, but they still functioned as religious centers ruled by bishops as well as centers of defense.

In the eighth century, the popes had summoned the Frankish rulers, Pepin the Short and Charlemagne to Italy to defend them against the Lombards. Especially as a result of Charlemagne's campaigns, the northern half of Italy came under Frankish rule. After Charlemagne's death in 814, law and order collapsed along with the central government, but the Frankish nobles left behind by Charlemagne remained as the power in the countryside while the bishops ruled the cities.

The turmoil following Charlemagne's death attracted waves of Muslim raids. These raids reached their peak in the ninth and tenth centuries, and, at one point, the Muslims even controlled part of Rome. Eventually, they were driven out, leaving the Frankish nobles in the countryside to fight one another for control of Northern Italy. Holding the balance of power in these struggles were the bishops in the towns. In order to enlist the bishops' aid the Frankish nobles promised various rights to them. Typically, the first of these rights was to build their own fortifications. Since such projects were expensive, the Franks also gave the bishops the right to collect taxes. And along with that would come certain judicial rights that also brought in court fees. Over time, the bishops' power and their desire to break free from the nobles steadily grew.

Luckily for the bishops, a strong German state with interests in Italy was emerging under Otto I. At the pope's request, Otto came down and crushed the power of the nobles and left the bishops in the cities as his agents of control in Northern Italy. This

resulted in two things. For one thing, the pope rewarded Otto in 961 with the Roman imperial title that Charlemagne had been given 160 years before. For the next 850 years, the aura of the imperial title would influence German rulers' policy and be the cause of ruin for Germany. However, at this time, a strong Germany, or Holy Roman Empire as it came to be called, was useful for protecting the peace in Italy. Second, the Italian cities, now freed from the nobles, started to take the offensive against the Muslim raiders. By 1200, Italian navies and merchants would be powerful enough to dominate the Mediterranean, help the Crusaders conquer and maintain their states in Syria and Palestine, and even conquer Constantinople in 1204.

Together, these factors brought peace and security from the Muslims and Frankish nobles, which led to the revival of towns and trade. At first, this benefited the bishops ruling the cities, since it brought in more taxes from trade. But it also meant the rise of a middle class of artisans and merchants in each city who were increasingly dissatisfied with living under the rule of the bishops. Eventually, they rose up against the bishops and overthrew them, establishing independent town governments known as communes. As nobles moved into the towns where many of them took up trade and merchants seized more and more political power, the distinction between nobles and middle class became somewhat blurred. What emerged in Italy was a new nobility known as *magnates* (literally "great ones") that was a fusion of these two groups.

It is important to note that while we talk about Italy as a country, it still existed as a patchwork of different and competing states. Northern Italy, in particular, was made up of a large number of independent city-states, the most important being Venice (a former Byzantine city), Genoa, Pisa, Milan and Florence. It was these cities that led the way for Western Europe to emerge from the Early Middle Ages. Their example and wealth would help spark a similar revival of towns north of the Alps. However, as we shall see, the political development of Northern Europe would be quite different from that of Italy, giving rise to the emergence of what would be our modern nation states.

The Turbulent World of the Italian City-state

The French city, Arles, especially symbolized the decline of towns after the fall of the Roman Empire. Its few remaining inhabitants fit their entire community inside the old Roman amphitheater for protection from barbarian & Arab raids. When it was cleared out for restoration in 1830, there were two chapels & more than 200 houses inside.

A major hazard to medieval trade was piracy, especially from Muslims based in Sicily and North Africa. However, by 1150, Genoa, Pisa, and Venice had eliminated much of this threat and established Italian naval dominance of the Mediterranean. This was a major factor in the success of the First Crusade and the Crusaders' ability to hold onto the coast of Palestine for 200 years. After the failure of the Second Crusade in 1144, all other crusades were transported by water.

Artist's sketch of a typical Mediterranean transport ship of the 1200s. The most important change from its Mediterranean predecessors is the use of triangular sails which were better for tacking into the wind. In the 1300s, the side steering oar will be replaced by the stern rudder, which will allow it to navigate the rougher waters of the North Atlantic, thus securing sea-borne trade with that region.

Peoples' loyalties then were more local than ours today. Families and local neighborhoods, known as *contrade*, competed with the city state for peoples' loyalty, sometimes with disruptive results, as seen in the opening of Shakespeare's *Romeo and Juliet*.

Below: Various symbols for medieval Siena along with the flags for each of its 17 *contrade*.

The town of San Gimignano (above) still has 13 of its original 70 towers. However, they were for the protection & prestige of individual families competing against one another rather than for the defense of the city, whose population probably never exceeded 3,000.

The Italian city-states fought fervently to maintain their liberty, especially the freedom to pursue business without interference from nobles and the Church. In deference to their commercial interests, cities typically called up militia in rotation to minimize disruption to business. The militia, who formed the backbone of the city's army, were mainly drawn from the artisans and shopkeepers who could afford weapons and armor.

While infantry militia formed the core of Italian city-states' armies, there were nobles, many or most of whom had moved into town, who fought as heavy cavalry like their comrades in the north. However, some of them still wielded the lance with two hands like the Byzantine cataphract. Still others used the lance overhand. In the North, European knights by 1100 mostly held the lance couched under their armpits to maximize the shock effect of their charging horses.

By the late 1200s Italian knights had adopted the heavy barrel helm to protect themselves against a nasty new weapon, the crossbow, which town militia could use effectively against the heavily armed nobles and the Church tried unsuccessfully to outlaw in an attempt to preserve the traditional social order. Crossbowmen from the city-state Genoa were in especially high demand across Europe, their

weapons being more powerful than English longbows, but also slower to reload and fire.

Guelphs and Ghibellines. Keep in mind the popes were also secular rulers heavily involved in the politics and warfare of the time. Their main enemies after 1075 were the Holy Roman Emperors in Germany who claimed sovereignty over Church elections.

The struggle between Popes and emperors, which lasted over 200 years, involved the Italian city-states caught in between. In each city there were two factions: the Guelphs who supported the Pope and the Ghibellines who backed the emperor. The factional struggle between these two groups largely resembled that between Oligarchs and Democrats in the ancient Greek polis.

The reasons one city went Guelph or Ghibelline typically had nothing to do with ideology. Florence, for example, supported the Guelphs because the Popes had given them the right to collect taxes for the Church in Tuscany.

Similar to modern gangs, Guelphs and Ghibellines were often identifiable by the side of the hat on which they wore a feather or how they cut their fruit.

Complicating matters further was the split in each city between Guelphs and Ghibellines. Landed nobles typically supported the Ghibellines while merchants joined the Guelphs, sometimes because they could collect taxes for the pope. However, a faction or city would often side with Guelphs or Ghibellines, or switch sides if it was convenient, simply because their rivals supported the other side.

To make matters more confusing around 1300, Guelphs in Florence split between the Black Guelphs who supported the pope and White Guelphs who opposed him.

Sometimes exiles from one party would join a rival city against the ruling party in their own city. This was the case at the Battle of Compaldino where Florentine Guelphs fought

alongside the Sienese army against Florence then ruled by Ghibellines.

At first, most Italian city-states supported the Guelph faction in their efforts to win independence from the German emperor, Frederick I Barbarossa. They succeeded in 1176 at Legnano when, against all expectations, the city-state militia defeated the supposedly invincible German knights.

One of the major battles between Guelphs and Ghibellines took place at Montaperti in 1260 when the Guelph city of Florence fought the Ghibelline city of Siena. However, on the Sienese side were Florentine Ghibellines who wanted to gain control of their city.

Although the Florentines heavily outnumbered Siena's army, the battle turned when a Florentine merchant, Bocca degli Abati, who was sympathetic to the Ghibelline cause, cut off the hand of the Florentine standard bearer.

When the Florentines saw their standard fall, they panicked. Out of an army of 35,000 Florentines and their allies, some 15,000 were cut down in the ensuing rout. In the *Inferno*, Dante, who was a Guelph sympathiser, gave Bocca degli Abati a special place in Hell for his treason.

A common rallying point for townsmen on the battlefield was either a cart (*caroccio*) or a portable bell tower (*martinella*).

TOWARDS THE RISE OF TOWNS IN WESTERN EUROPE: THE AGRICULTURAL REVOLUTION OF THE MIDDLE AGES

Until this century, the vast majority of people spent their lives involved in one basic occupation: getting food, either through hunting and gathering, herding, or agriculture. When these people could produce a surplus, they were freed to do other things, which provided the basis for towns, cities, and civilization. Without the ability to produce surplus food, no civilization would be able to survive. Therefore, it should come as no surprise that the first step in building a new civilization in Western Europe was developing ways for producing a surplus of food.

Europe (c.1000 C.E.) Before discussing these new agricultural techniques, it is useful to look at the state of Medieval life and agriculture in the Early Middle Ages. The vast majority of peasants were *serfs*, bound to the soil and service of a lord who owed them protection in return for work in his fields. These serfs lived in villages, isolated pockets of farmland in the midst of a vast wilderness of forests, thickets, and marshes. Typically, a village would have several acres of cultivated fields, a wooden castle or manor house for the lord, a peasant village, a parish church, and a mill. A village might be equivalent to a manor, the economic unit given to support a noble. However, it could just as well be divided into several manors to support several nobles or be only one of several villages making up a large manor.

The village had to be self-sufficient because it was virtually cut off from the outside world. Roads were poor and brigands or local lords constantly threatened travel. Raids from neighboring nobles and such invaders as the Vikings, Magyars, and Moslems also kept most people huddled under the safety of their lord's castle walls. As a result, the flow of trade and commerce was reduced to a fraction of what it had been during the Pax Romana. Compared to the thriving Byzantine and Islamic cultures to the south and east, Western Europe was a fragile outpost on the western fringe of civilization.

Europe's agriculture reflected this low level of culture. The plow used then was still the scratch plow that worked fine in the thin dry soils of the

Mediterranean, but was not very suitable for the wetter, deeper soils of Northern Europe. Such a plow might be reinforced with iron, or it might be nothing more than a curved digging stick. The main source of power for pulling the plow was the ox hooked up by a yoke harness that pulled at the neck. Although slow, the ox was more than some peasants could afford. As a result, they had to pull their own plows or dig with spades (known as *delving*). Finally, the peasants used the two-field system, where one field lay fallow to reclaim the soil's nutrients while the other field was being cultivated. This left only fifty percent of the farmland for use in any given year. As a result, crop yields were very low. In the Roman Empire, for every bushel of seed grain planted, four bushels would be harvested. In the Early Middle Ages with the poor techniques being used, this ratio dropped to one and a half or two to one. In other words, a full half or more of a peasant's harvest had to be saved as seed grain for next year's planting. In years of famine, this led to serious difficulties. Given these limits, it should come as no surprise that population remained low and grew at a very slow rate, if at all.

One has to be very careful when generalizing about what techniques were used where. This is because we have little evidence to go on, especially concerning the peasants, whose lives were of little concern to the monks writing religious histories. Also, the poor communications between manors meant that widely different techniques and tools might be used in a fairly local area. However, it does seem likely that the light scratch plow, oxen, yoke harness, and two-field system were in general use in Western Europe in the Early Middle Ages. Then came some changes that would lay the foundations for more advanced civilization.

First stirrings of revival. It is impossible to say when population first started expanding in Western Europe, although we can make some educated guesses. For one thing, the climate seems to have turned warmer in the 800's. We base this on tree ring evidence and the fact that the Vikings could sail in northern latitudes unobstructed by ice. The warmer climate meant longer growing seasons, better harvests, and thus a healthier and growing population. Major plagues that had hit intermittently since the later Roman Empire also ceased after 743 C.E. This might be partly a result of the better-fed population having more resistance

to disease. Finally, a certain amount of political stability had returned to Western Europe by 1000 C.E. The feudal system, whatever its faults, was providing at least a minimal amount of security to Europe. Along with this, the invasions of Vikings, Magyars, and Muslims were letting up by this date. The increased stability created by all these factors helped provide the conditions needed for population growth and economic revival. This brings us to new farming techniques that would greatly expand food supplies and lead to the rise of towns.

An agricultural revolution. The first of these techniques was the *three-field system*. Originally, the spread of civilization to Northern Europe brought with it the two-field system. This was well suited to the climate of the Mediterranean with its hot dry summers and one growing season in the cooler, wetter winters. The more temperate climate of Northern Europe allowed growing seasons in both summer and winter. However, planting two crops a year would exhaust the soil if peasants used the old two-field system. As a result, peasants divided their farmland into three fields, one for winter crops, one for summer crops, and one to remain fallow. The use of the fields was rotated each year. A second part of the system, in order to prevent soil exhaustion, was to use different crops that took different nutrients from the soil. The winter crop typically would consist of winter wheat or rye, and the spring crop would be either spring wheat or legumes (beans or peas). The greater variety of crops provided people with a more balanced diet. Also an advantage of legumes is that they take nitrogen out of the air rather than the soil, and when buried, actually replenish the soil with nitrogen. (The Romans referred to this as "green manuring".) The following charts show how the two systems work.

TWO-FIELD SYSTEM

| | Field 1 | Field 2 |
|----------|-------------|-------------|
| Year I | Winter crop | Fallow |
| Year II | Fallow | Winter crop |
| Year III | Winter crop | Fallow |

THREE-FIELD SYSTEM

| | | | |
|----------|-------------|-------------|--------|
| Year I | Winter crop | Summer crop | Fallow |
| Year II | Fallow | Winter crop | Summer |
| Year III | Summer crop | Fallow | Winter |
| Year IV | Winter crop | Summer crop | Fallow |

Consider what the changeover from the two-field system would have meant to a peasant village farming 60 acres. In the old system only 30 acres would be planted each year. In the new three-field system 40 acres would be planted, an increase of 33%. Also, peasants would plow the fallow land twice to keep weeds down. In the two field system this mean plowing all 60 acres once plus the 30 fallow acres again, 90 acres of plowing in all. The three-field system, involved plowing all 60 acres plus only 20 acres of fallow again, a total of only 80 acres of plowing. Thus while producing 33% more food, the peasants were plowing considerably less, especially considering what hard work plowing was back then. The extra time saved could be used for clearing new farmland from the surrounding wilderness, which, of course, meant even more food. Likewise, the extra food meant more people from population growth, who would also clear new lands to produce more food, and so on. Eventually, enough new land would be cleared and surplus food produced to support population in towns.

Another major development in farming was the *heavy plow* that could cut through the deep, wet, and heavy soils of Northern Europe much better than the light scratch plow. It had three basic parts: the *coulter* or heavy knife that cut through the soil vertically, the *plowshare* that cut through the soil horizontally, and the *mouldboard*, which turned the soil to one side. Some models had two wheels that acted as a fulcrum to keep the plow from getting stuck. There were two advantages to this kind of plow. First, it cut the soil so violently that there was no need for cross plowing as there was with the scratch plow. This saved time, which could be used for, among other things, clearing more land and producing more food. Second, the heavy plow created *furrows*, little ridges and valleys in each plowed row. In times of drought, water would drain into the valleys and ensure some crops would survive. In times of heavy rains, the crops on top of the ridges would not get flooded out. As a result, peasants could usually look forward to at least some crops to harvest even in bad years. The furrows the heavy plow created also meant that the rich alluvial bottomlands by rivers could be farmed without their frequent floods doing too much damage. As with the three-field system and crop rotation, the heavy plow also fed into the feedback cycle of more food, population growth, etc.

Left: The wooden scratch plow that was suited for the thinner soils of the Middle East and Mediterranean, but not the thick heavy soils of Northern Europe.

Right: the heavy plow.

The heavy plow had an impact on peasant society and land holding patterns. Being heavy, it required as many as eight oxen to pull it compared to two oxen on the scratch plow. Since few peasants could afford their own teams, they would combine their ox teams and hook them to one plow. Occasionally, disputes might arise as to whose land would be plowed first, especially if the weather had been bad and it was doubtful that all the fields could get plowed in time for a good crop. As a result, peasants split their lands into long strips and interspersed them among other peasants' and the lord's strips. Some peasants might have 50 or 60 strips spread out over the manor. The advantage of this was twofold. First of all, it ensured that everyone got at least some land plowed. Second, the long strips of land meant that the plow team did not have to turn as much, one of the most difficult aspects of plowing, especially with four rows of oxen to increase the turning radius. The heavy plow also created a more cooperative peasant society and caused small hamlets to combine into larger villages in order to share ox teams.

The last major development in farming was a new source of power, the plow horse. Several factors allowed the use of the horse in Western Europe. The invention of the horseshoe (c.900 C.E.) prevented the hooves of the horse from cracking in the cold wet soil. The horse collar let the horse pull from the chest rather than the neck. This increased the horse's pulling power from about 1000 lbs. (with the yoke harness) to as much as 5000 lbs with the horse collar. Finally, cross breeding to make larger warhorses also provided the peasants with larger

plow horses. Although it could not pull any more than an ox, the horse did have two advantages. It could pull up to fifty percent faster than the ox, and it could work one to two hours longer per day. The one drawback was that the horse ate a lot. Overall, despite eating more, the plow horse could increase farm production as much as 30 percent for those peasants who could afford horses. As with the three field system and heavy plow, this led into the feedback cycle of producing more food, population growth, and developing new lands for even more food production, etc.

There were some interesting side effects of the use of the horse. Being fifty percent faster than oxen, horses could bring food into a town from outlying villages fifty percent farther away without taking any more time than before with an ox team. Increasing the radius of the surrounding farmland supplying a town by fifty percent more than doubled the area of farmland and amount of agricultural produce available to support that town, and, subsequently, the potential size of the town itself. In addition, the replacement of the two-wheeled cart with the four-wheeled wagon with a hinged post for greater maneuverability increased the amount of grain a peasant could bring into town.

We should keep in mind the limits to medieval agriculture. While a yield to seed ratio of four to one was good back then, farmers today expect at least ten times that. What this means is that for centuries it took ten farmers to create enough surplus to support one townsman. Still, along with the greater stability brought by feudalism, the increased food production brought on by the agricultural revolution of the Middle Ages was essential for the revival of towns, without which our own civilization would not have evolved.

THE RISE OF TOWNS DURING THE HIGH MIDDLE AGES (c.1100-1300)

From trade fairs to towns. In the twelfth century, towns and trade in Western Europe, which had long been in decay since the end of the Roman Empire, saw a renewed outburst of energy. A combination of four factors would lead to this. First, there were the old Roman cities in Italy that had evolved from centers of defense into thriving towns with a strong middle class primarily concerned with trade and manufacture.

Second, another area, Flanders (roughly equivalent to modern Belgium), soon saw the development of towns and trade also. Crucial to this was the wool industry started by a new monastic order, the Cistercians. These monks were part of the ongoing cycle of Church corruption and reform that usually started with the monasteries. To protect their spiritual purity from the corruption of the outside world, they would found their houses "far from the haunts of men." Oftentimes, this was on hilly rocky ground that was often unsuitable for farming. Other uses were found for it, in particular raising sheep. The Cistercians were well organized and very good at raising sheep and wool, which they traded to Flemish merchants, who started a wool industry and towns.

However, the Flemish had a problem that limited the scope of their operations: slow weaving on the old hand loom. Luckily, an improved mechanical loom came up from Muslim Spain sometime in the eleventh century. This device, possibly originating in China, eliminated hand weaving the weft thread in and out between each individual warp thread. Instead, foot pedals attached to every other warp

thread would raise those threads and speed up the process of weaving in one direction. Another foot pedal would raise the other warp threads for the weft coming back. This increased wool production, but the traditional method of spinning thread with the drop could not keep up with the pace of weaving. Not until the thirteenth century, thanks largely to the crusades and increased contact with the East, was the spinning wheel introduced, which quickly pulled and spun wool through a spindle and wound it on a bobbin. Woolen production jumped by a factor of ten times and Flemish woolens became the basis of a thriving urban culture in northern Europe.

Indeed, Flemish wool was a highly valued commodity, reputedly being as smooth as silk. The tendrils of Flemish trade stretched far and wide, but especially across the Channel to buy rough English wool for weaving into fine Flemish product. The close economic ties this bred between England and Flanders, then a French vassal, would help lead to the Hundred Years War. The influence of Flemish woolens also reached southward to Italy and beyond, touching off trade at intervening points in France where towns next revived.

The emerging feudal order helped make possible two other factors vital to the rise of towns and trade. One was the agricultural revolution that could support town populations. The other was the end of Viking and Arab raids that made the roads safer for trade. These four factors helped create more political stability, which encouraged merchants to take to the roads once again. In the middle of the old Roman trade routes linking Italy and Flanders was the French county of Champagne, whose counts were shrewd enough to take advantage of this trade by sponsoring six annual trade fairs held in four rotating locations. Rather than robbing these merchants, the counts charged them for the use of booths, local justice, lodging, food, and protection. Among those attending these

fairs and providing the counts with revenues were wealthy merchants from Italy and Flanders.

The area of France where trade fairs started to revive trade

The excitement these fairs generated was infectious. So were the profits. Some jealous nobles attacked and robbed merchants traveling to the fairs. Others, being more far-sighted, worked to ensure safer travel so they could start their own fairs and make their own profits. With each new fair came greater incentive to stifle troublesome local nobles and increase political order. This in turn stimulated more trade fairs, more profits, more law and order, and so on.

Trade fairs could be boisterous exciting, and sometimes turbulent events requiring the strong arm of the local lord's justice.

Eventually fairs and trade became so common that merchants started settling down in permanent towns. Generally, such settlements were on well-traveled routes that could attract the trade of passing merchants. They also were under the protective walls of a lord's castle, an abbot's monastery, or a bishop's settlement. Many towns were brand new settlements, but others were outgrowths of already established communities. Even today, many European towns have a castle in or near them, evidence of their medieval beginning.

The impact of towns. More stable conditions had helped produce the rise of towns. The towns in turn helped create even more peaceful conditions with far reaching effects. For one thing, towns generated taxes in the form of money, a new more fluid kind of wealth vastly superior to land as the primary form of wealth. Previously, almost any noble with a castle and a stockpile of food could defy his lord by going under siege, since feudal armies were notoriously unstable and prone to breaking up after their terms of service (usually forty days) were up. However, the more powerful lords that could attract settlers for towns now had money from taxes. With that money, they could buy mercenaries, usually landless knights, who would fight as long as the lord could pay them. Such armies were more stable and allowed their owners to crush the power of their rebellious vassals and establish more law and order. The increased order would encourage more towns which would generate more taxes for the king and upper nobles, who could impose even more law and order, and so on. This would also feed back into the ongoing cycle encouraging trade fairs. All this led to two things: a rising class of townsmen and a money based economy, both of which would help lead to the rise of kings.

Money created another problem especially hurting the nobles and Church: inflation. At first, when towns were just getting started and there was little money in circulation, the fixed rent set by the original town charter seemed like a good deal. However, as more money came into circulation, prices rose, and the buying power of the fixed rents declined. This especially hurt the nobles and the Church. The nobles often took the short term expedient of selling freedom to their towns and serfs for one lump sum. This gave them some immediate cash, but wrecked much of their power, leading to the decline and eventual end of the feudal order.

The Church, with its wealth mostly in land and fixed rents, also suffered. It did have other options for raising money, namely selling church offices and indulgences (reprieves from punishment in Purgatory before being admitted into Heaven). Such practices were subject to abuse and led to popular discontent that cut into the Church's power and prestige. Eventually, that would lead to the

Protestant Reformation, which would destroy the Catholic Church's religious dominance in Western Europe.

As far as townsmen were concerned, nobles and churchmen first saw them as an asset providing them with taxes and militia. However, as the class of townsmen grew, so did tensions with their overlords. For one thing, townsmen (or *burghers*, from *burg*, the German word meaning town) felt increasingly stifled under a lord's rule. The two classes had very different values, the burghers being concerned with trade and commerce and their overlords being concerned with power and fighting. Therefore, one by one, towns started trying to gain their freedom. Some towns bought it with one big payment to the lord or fought for it, sometimes in long protracted struggles. For example, the town of Tours in France fought twelve wars before it finally won its independence.

Another tactic was to appeal to the king for support, since kings and townsmen saw each other as valuable allies against the nobles and Church in between. Eventually, the towns managed to break free and form *communes* (urban republics) like their counterparts in Italy. Oftentimes confirming the town's independent status would be a charter that would detail the specific duties and liberties the town and lord owed each other. Also, as serfs and towns bought their freedom, they came more closely under the king's authority, supplying him with taxes and loans.

Two other factors unique to the king gave him an edge over other nobles. One was his religious position as God's appointed ruler, which was symbolized by a churchman anointing him with oil in the same manner as Biblical rulers. The second factor was his position as the supreme judge of the land. When the kings were weak in the Early Middle Ages, this did them little good. However, as they rose in power, they could exercise their judicial powers more effectively, which in turn would give them more political power and so on.

All these factors, the rise of a money economy, the growing class of townsmen, and the kings' judicial and religious status gradually led to the decline of the medieval Church and nobles and the

corresponding rise of kings with money that could buy them two things. One was stable full time mercenary armies that would fight for as long as they were paid. The other was a bureaucracy drawn increasingly from the middle class. These new royal bureaucrats had several advantages over feudal vassals. For one thing, they were more loyal, being the king's natural allies against the nobles. Also, they were more efficient since they were generally literate and could keep records. Finally, they were easier to control because they were totally dependant on the king for their status. Also, they were paid with money, so the king could just cut their pay if they got out of line. This contrasted greatly with the land based economy of the Early Middle Ages when the king had to physically drive rebellious vassals from their lands. Although the rise of kings and national monarchies would be a centuries long process, it was the rise of towns starting in the twelfth century that set that process in motion and laid the foundations of the modern world.

The revival of learning and the rise of universities. As trade revived and spread into Muslim Spain and with the Muslim and Byzantine East, merchants also came into contact with the advanced learning in math and science that was thriving in those areas. (Another source of contact was the pilgrimage route to Santiago de Compostela in Spain, only surpassed in popularity as a destination by Jerusalem and Rome.)

Not that learning had completely died out in Western Europe. Among the bright spots were the universities established by Charlemagne (c.800) and other Carolingian rulers during the Carolingian Renaissance. Most of these were established as cathedral schools to train clerics who could double as bureaucrats.

In 1079, as more settled times were returning, Pope Gregory VII mandated the creation of Cathedral schools to educate the clergy. Such clergy could also support him in the Investiture Struggle against the German emperors. As these schools proliferated, many developed into universities. Among the most notable were:

- The University of Bologna (f.1088) in Italy, which specialized in canon (church) law
- The University of Paris (c. c.1119) coalescing from various monastery schools
- The Theological School of the Sorbonne in Paris (c. 1231)
- Oxford University (1167-85)
- The first college of Cambridge (1209)

Students would enter the university as early as age 14 and take part in 6 years of lectures in the liberal arts which were divided into two parts:

- The *trivium* ("three ways") of grammar, dialectic, and rhetoric
- The *quadrivium* ("four ways"): math, geom., astronomy, & music

Lecture comes from the Latin word for read, because lecturers would typically read from the only copy of the text usually available while students copied them down. Students could also rent 8-page sections (*peciae*) of the text that had been hand-copied (as were all books, including the master texts before the printing press came along after 1450.)

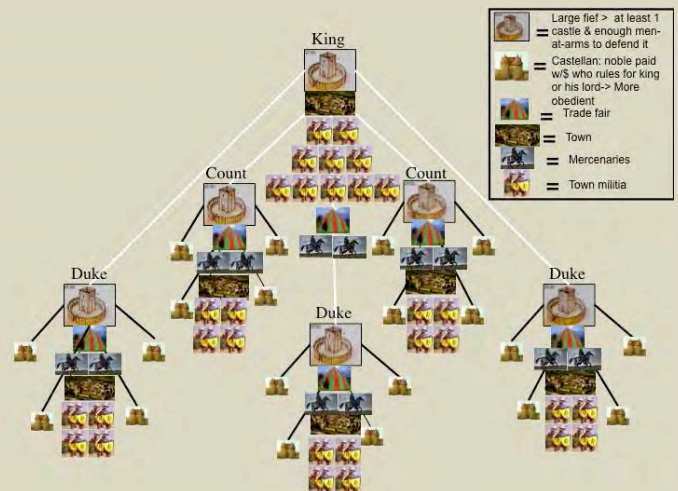

Next came 2 years of debate or disputations which led to examinations that could earn a degree in the Bachelor of arts. A Master's degree usually required one more year of further studies. That in turn qualified one to study law, medicine, or theology and earn a doctorate (from the Latin word for teacher). Altogether, this could involve up to 12 years of study.

Universities were almost always under clerical rule. Since the Church's laws and punishments were more lenient than those of secular authorities, universities also attracted a number of irresponsible young men who used the umbrella of the Church's protection to engage in

theft and other petty crimes. This, in turn, often led to bad relations and even violence between Town and Gown, sometimes making the atmosphere in medieval towns even more turbulent than usual.

Despite this more unsavory aspect, medieval universities were the basis of the revival of learning that has served as the basis for Western civilization to this day. The core and foundation of this learning were the works of Aristotle (384-322 B.C.E.), which the Arabs had especially preserved and passed on to the West. Aristotle's works would serve as the basis of Western learning and what is known as the Twelfth Century Renaissance. His influence, backed by the power of the Church, would totally dominate Western learning until the Scientific Revolution in the 1600s.

Towns and the Evolution of the Feudal Monarchy out of the Feudal System

The king needs armies to defend his kingdom, but has no money with which to pay them.

The king divides the kingdom into 5 parts, keeping 1 for himself and giving the other 4 as *fiefs* to *vassals*, who will defend their fiefs & owe him 5 knights each for 40 days a year. However, each vassal needs knights to provide to the king & for his own local wars.

Therefore, they each *subinfeudate* (subdivide) their respective lands into 5 parts, keeping one to live on and giving the other 4 as fiefs to *rear*

vassals who owe their lords 3 knights each for 40 days a year for his wars.

To meet his obligations & needs each rear vassal *subinfeudates* his fief into 5 fiefs, each with 1 manor able to support 1 knight. He keeps one for himself & gives the other 4 to vassals who personally owe him 40 days of service a year for his wars.

To take advantage of the growing trade, the king and all the counts and dukes hold trade fairs. To do this, they need to guarantee the peaceful travel of the merchants. As a result, they team up with their direct vassals to bring their rear vassals under control.

Having established peace in their realms, the king, counts, & dukes hold successful trade fairs that bring in money that they use to buy mercenaries who will fight full time for them. Using these mercenaries, they bring their barons under control and install castellans paid with money, giving them more control.

The towns, wanting freedom from their overlord dukes and counts, ally with the king to win independence from them, while remaining loyal subjects and allies of the king who safeguards peaceful trade.

[Back to flowchart](#)

IN PURSUIT OF SECURITY: MEDIEVAL LEAGUES AND GUILDS

The years when towns and trade were first reviving in Western Europe were precarious ones for the emerging middle class of merchants and artisans. Costly tolls levied by local nobles hampered trade when times were peaceful, while more turbulent times could see each of those nobles cutting off trade and marauding merchants on the road. Different weights, measures, and standards of coinage complicated transactions between merchants of neighboring towns. Famine could drive prices up dramatically, thus cutting down the flow of trade and causing turmoil among the workers who wanted higher wages to keep up with rising prices. Given such a dangerous world for the medieval merchants and artisans, it should come as no surprise that they formed associations, leagues and guilds, to protect and promote trade. These were not examples of free enterprise, however. Their purpose was to exclude outside competition from their markets since the evolving market economy was seen as too fragile to sustain much competition.

Leagues. In northern Europe, towns would band together in leagues to establish collective security. The most important of these leagues was the *Hanseatic League*, which was centered on the city of Lubeck in the southwest corner of the Baltic Sea. At the height of its power (c.1350 C.E.) the League contained over seventy German cities throughout the Baltic and North Seas. It kept an effective monopoly on the trade in this area by keeping out Russian, Scandinavian, and English competition. When pirates, local lords, or even kings threatened their trade or freedom, the League's forces could successfully defend their interests. The king of Denmark found this out to his dismay in 1370 when he tried to encroach on the League's territory and was driven back. The Hanseatic League dominated the trade of the Baltic and North Seas in the north much as the Italian cities dominated the Mediterranean trade in the south.

Besides common military action, the Hanseatic League carried out other measures to protect and promote trade. For one thing, it established common weights, measures and coinage throughout its member cities. This cut down on the time-consuming hassles of having to convert from one weight and measurement system to another each time a new business transaction took place. Today we are in the final stages of this standardization process, as the metric system is being pushed for worldwide use.

The Hanseatic League's success was also based on more advanced business techniques, in particular the use of credit. With a cash economy, a merchant could only buy as many goods as he had the cash on hand to pay with, which severely limited the scope of his activities. With credit that merchant could borrow more money than he actually had and use it to buy goods that he could sell for a larger profit than with a cash economy. This was because he was borrowing, buying, and reselling on a much larger scale (even after repaying the loan) than he ever could if he were dealing strictly with cash. As the merchant's credit rating improved, he could borrow ever-larger sums of money, oftentimes in several places at a time through the use of his agents, which vastly expanded the scope of his activities, his profits, and his credit rating. Buying in larger volume also allowed him to sell each unit of goods more cheaply and thus undersell other merchants not dealing in credit. In such a way, the Hanseatic League established a virtual monopoly on trade in the Baltic and North Seas.

The political expansion of the German people also helped the German cities of the Hanseatic League. At this time, German peasants and the crusading order of the Teutonic Knights were expanding into the interior of Eastern Europe against the Slavic peoples there. Meanwhile, the German cities founded colonies in their wake, thus increasing their economic power over the Baltic Sea and further restricting competition there.

Although the Hanseatic League was the most important of the medieval town leagues, it was by no means the only one. There were several leagues of towns along the Rhine whose main concerns were to stop the raids of local nobles on trade and to curb the tolls those nobles imposed on goods passing through their territory. The most famous of these leagues, the Swabian League, had over eighty member cities at its height (late 1300's) and was strong enough to challenge the dukes of Austria and Bavaria. In Flanders, there was a league of twenty-two towns whose purpose was to buy raw wool from England. Another league of seventeen towns in Champagne County, France regulated marketing practices at trade fairs. Whatever their functions, the cumulative effect of leagues was to improve the trade and economy of Western Europe. And that in turn contributed to the rise of kings and more stability.

Guilds served much the same function on a local level as leagues did on a wider geographic level: protecting their members from the dangers of outside world, whether they were marauding nobles

and bandits, economic ruin, or outside competition. Originally each town would have one guild encompassing all crafts. However, as the towns grew, the guilds evolved into various specialized guilds: merchant, goldsmith, armorer, tailor, bargemen, etc. By 1200 C.E., Venice had fifty-eight guilds, Genoa thirty-three, Florence twenty-one, Cologne twenty-six, and Paris one hundred. The purpose of each guild was to exclude outsiders from practicing that guild's craft or trade within the city walls. Although this virtually eliminated free enterprise, it did provide a stable atmosphere in which the newly evolving crafts and trades could develop and survive.

Guilds went much farther than excluding outside competition from within their walls. In fact they controlled just about every aspect of the town's economy, in particular wages, prices, quality of goods, and guild membership. For example, an armorer would buy the materials he needed through the guild at a set price, not on his own for whatever price was cheapest. His workers worked for the number of hours and wages set by the guild. His armor had to be of certain quality meeting the guild's specifications. He could not advertise beyond setting one example of his work in his window. The guild also determined the price he could charge so he would not get an advantage over other members of the guild. Set prices also reflected the Church's displeasure with profits.

Training for and admission into the guild were also strictly regulated. Apprenticeship was almost always restricted to sons or nephews of guild masters, something that caused anger among the common laborers. Typically, a master craftsman would send his son to another craftsman for apprenticeship at the age of ten to twelve years. The boy would live in the master's home, work in his shop, and learn the craft in an apprenticeship lasting from three to fifteen years. At the end of his training, the apprentice would usually get a gift of money from the master to help him start his own business. He then became a *journeyman* who worked as a day laborer for different masters until he could save enough money to start his own shop. When he was ready, the journeyman would be examined by the guild masters for his technical ability, oftentimes having to produce a *masterpiece* to show his proficiency at the craft. If he passed the exam, and there was room in the guild, he became a master who shared in the limited, but fairly stable market established by the guild for its members.

The guild was more than a business association. It was also a social and political organization that looked after the welfare of its members. It provided

justice by settling disputes between its members. It supervised the morals of its members in such matters as public fighting, drunkenness, and a dress code. It provided insurance against fire, flood, theft, prison, and old age (for those few who survived that long). It paid for members' funerals and for masses and prayers to free their souls from Purgatory. The guilds would also build hospitals, almshouses, schools and orphanages for the many orphans in society back then.

The guild was also a source of pride for its members. Each guild had its own guildhall where meetings and social functions were held. On the day celebrating its patron saint, a guild would put on parades and religious plays. Guilds would also dedicate to the town cathedral stained glass windows depicting biblical scenes that were also concerned with that guild's particular craft.

Guilds, like leagues, caused Europe's economy and trade to improve, which made possible the rise of kings and more stable conditions. However, those very kings who profited from guilds and leagues were largely the cause of their decline in the 1400's. For one thing, the stable conditions protected by the kings made the guilds' protective restrictions unnecessary. In spite of this, the guild masters who ran the towns restricted membership even more than before while maintaining strict price and quality controls on their goods. Earlier, such practices had been good since they had protected a fragile trade vulnerable to the harsh conditions of the time. By the late 1400's, those same practices that had once protected the guilds now worked to destroy them. Restrictive membership and low wages, even in time of inflation, led to worker revolts in many cities. Even more devastating was the competition from outside of town. Rich merchants started *cottage industries* where they moved production outside the city walls (and the guilds' jurisdiction). Here they could pay individual peasants lower wages to produce wool and undersell the guilds which were still locked into their controlled wage and price structure. As a result, guilds went into decline.

The rise of strongly centralized states in the Later Middle Ages also hurt leagues, because the kings now protected trade and also saw the leagues as rivals for political power. At the same time, stability and trade fostered by the rise of kings sent explorers looking for new markets. The discovery of new trade routes to America and around Africa shifted trade away from the Baltic and North Seas, thus hurting the German leagues.

Daily Life in Medieval Towns

Carcassonne in southern France, one of the best preserved medieval cities

Upon approaching a town, one would first encounter its fortifications, which besides protecting it from enemies, also marked a clear distinction between town and country. Suburbs were discouraged or forbidden because they could offer cover to approaching enemies.

In addition to a town's fortifications, one would typically see towers inside a city. Each tower would belong to a noble family and served as a status symbol as well a fortified center of defense against other nobles they may be feuding with, such as the Capulets and Montagues (real families) in Verona, Italy and portrayed by Shakespeare in *Romeo and Juliet*. San Gimignano in Tuscany (below) is probably the best surviving example of this phenomenon, although only 14 of its original towers survive.

Houses were typically made of a wooden frame with the gaps filled in with wattle (a woven mat) and daub (mud plaster). Such buildings were prone to fire and had to be redaubed every year or two.

Typically, merchants and craftsmen would occupy an upstairs apartment, while having their shop on street level.

Above: Street scenes in medieval Florence, but typical of other towns across Europe then. Oftentimes, each district would specialize in one type of product, such as woolen textiles seen here. Notice the crowded unpaved street and the pig, which was allowed to run loose to eat garbage and children's homework.

Although the 6-day work-week was the norm in the Middle Ages, there were also numerous festival days to commemorate various saints that people got off work. On the day of the patron saint of a particular guild, its guild members would typically stage a parade for the entertainment of the whole town.

Town life had its hazards as well. Two in particular, thanks to the crowded conditions, were fire and disease. In the absence of modern vacuum pumps, medieval townspeople had little to put out fires except grappling hooks to pull down houses in the path of the fire to create a firebreak. The worst-case scenario was a fire starting during a dry season on the windward side of town on a windy night when people were less alert. If dealt with quickly, the fire might be contained. However, windy conditions could rapidly multiply the problem exponentially, as happened to London in 1666. Between 1200 and 1225, the French town of Tours burned down six times.

The other hazard, disease, was compounded by the lack of sanitary facilities that attracted rat disease-bearing insects and rats. Not having any accurate ideas on what caused diseases, the only options during an epidemic were quarantining (confining) the sick or fleeing town. The worst-case scenario was the Black Death in the 1300s, which probably wiped out 30% of Europe's population overall, although in the cities that rate typically soared to 60-70%. The allure of town life and opportunities attracted migrants from the countryside, and they were needed, since towns often could not sustain their populations through natural increase.

There was a medieval saying that town air made one free. However, it also made one sick. Not until public sanitation and modern medicine developed in the late 1800s would life expectancies in towns and cities equal or exceed those in the countryside.

THE RISE OF THE PAPAL MONARCHY IN THE MIDDLE AGES (c.900-1300)

The posthumous trial of Pope Formosus

Introduction: the plight of the Church in the Early Middle Ages. Few stories better illustrate the problems of the medieval Catholic Church than the story of Pope Formosus. When this pope died in 896, his troubles were far from over. A personal enemy became the new pope and had Formosus' body dug up and put on trial. To no one's surprise, the late Formosus was convicted of illegally seizing the papal throne. His body was stripped of its priestly vestments, the fingers on his right hand (used for giving the benediction) were cut off, and his body was thrown into the Tiber River. Not surprisingly, the rest of the Church, ranging from bishops, archbishops, and abbots down to the lowliest monks and parish priests, was also seething with corruption.

The Church's wealth, some 20-30% of the land in Western Europe, was a big part of the problem. With little money in circulation at this time, land was the main source of wealth and power, making the Church the object of the political ambitions of nobles throughout Europe. Naturally, such nobles, who were warriors by trade, usually ignored and even trampled over the religious interests of the Church.

The abbey of Cluny where a major Church reform movement started c.910.

The zeal for reform (910-1073). Even in such troubled times, the Church's ongoing cycle of corruption and reform meant there were always men of religious conviction determined to set the Church

back on its spiritual path. As so often happened, reform started in the monasteries, in this case in the monastic house founded at Cluny, France in 910 C.E. The monks of Cluny placed themselves directly under the pope's power and out of the reach of any local lords. That meant virtual independence from any outside authority, since the popes were too weak to exert any authority from so far away. Technically, they were Benedictines and there was no separate order of Cluniac monks, but their agenda of reforms became so widely adopted that they have been referred to as Cluniacs ever since. Over the next 150 years, Cluniac reforms spread to hundreds of monasteries across Western Europe.

The zeal for reform was also strong in Germany, especially among the upper clergy and the emperors. The emperors saw church reform as a way to weaken the power of the nobles trying to control church lands and elections. By the same token, devout bishops and abbots looked to the German emperors for protections from ambitious nobles. As a result, both German emperors and German clergy supported the growing reform movement. Emperors put reformers into church offices throughout Germany. Such men were generally loyal to the emperor since they owed their positions to him and saw him as the main defender of reform.

The emperor, Henry III, even appointed four reform popes. One of them, Leo IX, carried out numerous reforms against simony (selling church offices), clerical marriage, violence, and overall moral laxity among the clergy. He even felt strong enough to tangle with the patriarch in Constantinople, thus causing a *schism* (break) within the Church in 1054 that was never healed. Since that time, the Roman Catholic and Greek Orthodox Churches have functioned as two separate Churches. Consequently, by the mid eleventh century, the popes were taken seriously as a real moral force in Western Europe. However, a storm was about to break that would destroy relations between Church and Empire.

The Investiture Struggle (1073-1122). In 1056, the reform Church's main ally and guardian, Henry III, died leaving a child, Henry IV, as his successor. This deprived the Church of any effective imperial protection until the young emperor came of age. As a result, the popes had to seek new allies, and

settled on the Normans in Southern Italy and the dukes of Tuscany in Northern Italy. Both of these were enemies of the German emperors, thus creating a tense situation between the popes and Henry IV when he came of age. One reform adding to the tension was the creation of the College of Cardinals whose job it was to meet in private to elect a new pope. Designed largely to keep the turbulent Roman mob out of papal elections, it also kept the German emperors out of direct participation, although they still could veto any choice the College of Cardinals made.

Another problem was the pope, Gregory VII, an ardent and stubborn reformer who agitated to replace imperial with papal control of Church elections. Growing suspicion and tension between pope and emperor finally erupted in the Investiture Struggle over who controls Church elections and invests (bestows) the bishops and abbots with the symbols of their power.

The stakes in this fight were high on both sides. Henry needed control of the bishops and abbots to maintain effective control of his empire. Pope Gregory felt the Church had to free itself from outside secular control if it were to fulfill its spiritual mission. There was also the larger question of who was the real head of the Christian world: the Universal Empire or the Universal Church. Although the Byzantine emperor usually held sway over the Eastern patriarch in Constantinople, this question of supremacy, going back through Charlemagne to the later Roman Empire, had never been resolved in the West.

Meanwhile, the pope stirred the German nobles into rebellion against Henry. When Henry and his bishops declared Gregory a false pope, Gregory excommunicated Henry. Excommunication could be a decisive weapon since it released a ruler's vassals from loyalty to him until he did penance to get accepted back into the Church. As a result, Henry did such penance by standing barefoot in the snow outside the pope's palace at Canossa.

However, the struggle was hardly over. Gregory was driven from Rome and died in exile in the Norman kingdom to the south, while Henry's reign ended with Germany torn by civil war and revolts. Finally, a compromise was reached where only clergy elected new bishops and abbots, but in the presence of an imperial representative who invested the new bishop or abbot with the symbols of his secular (worldly) power. Although the struggle between popes and emperors continued for centuries, the popes had won a major victory, signifying the Church's rising power and a corresponding period of decline for Germany.

The Papal monarchy at its height (1122-c.1300).

The papal victory in the Investiture Struggle and the higher status it brought the popes led to many more people turning to the Church to solve their problems, in particular legal ones. Canon (church) law and courts were generally seen as being more fair, lenient and efficient than their secular counterparts.

However, the more the Church's prestige grew, the more its courts were used, and the more its bureaucracy grew. As a result, the popes found themselves increasingly tied down with legal and bureaucratic matters, leaving less time for spiritual affairs. The popes of the 1200's generally had more background in (church) law than theology. By and large they were good popes, but also ones with an exalted view of the Church's position. The most powerful of these popes, Innocent III (1199-1215), even claimed that the clergy were the only true full members of the Church.

**My enemy's enemy is my friend:
Who sided with whom in the
Investiture struggle**

The Investiture struggle was a bitterly fought conflict on both sides. Pope and emperor stirred each other's subordinates into revolt. The reform bishops, appointed up to this time by the emperor, generally supported him against the pope.

Pope Innocent III

Unfortunately, growing power and wealth again diverted the Church from its spiritual mission, and led to growing corruption. Two other factors aggravated this problem. One was the rising power of kings, which triggered bitter struggles with the popes over power and jurisdiction. Popes often used questionable means in these fights, such as overuse of excommunication, declaring crusades against Christian enemies, and extracting forced loans from bankers by threatening to declare all debts to the bankers erased if the loans were not granted. A second problem was inflation, which arose from the rise of towns and a money economy. The Church, with its wealth based in land, constantly needed money and therefore engaged in several corrupt practices: simony, selling indulgences (to buy time out of Purgatory for one's sins), fees for any and all kinds of Church services, and multiple offices for the same men (who were always absent from at least one office).

All these factors combined to ruin the Church's reputation among the faithful and undermine its power and authority. Eventually, they would lead to the Protestant Reformation, shatter Christian unity in Western Europe for good, and help pave the way for the emergence of the modern world.

Those troubled popes

Papal history after the disintegration of Charlemagne's empire was both dangerous and fraught with scandals. By the late 800s, the papal throne had sunken to being little more than a political prize fought over by rival Roman families. Therefore, four popes were murdered between 882 and 984: John VIII (872-82), Stephen VI (896-97), Benedict VI (973-74), and John XIV (983-84). During another six-year period, there were seven popes and one anti-pope, four of them in one year. And of course, there was poor old Pope Formosus whose body was dug up and put on trial after he died.

In addition to murders, there were also plenty of scandals, or rumors of scandals that tend to thrive in such an environment. One woman, Theodora, had her father make her lover pope Sergius. When he died in 911, her mother, Marozia, had her husband make her lover Pope. One pope sold the papacy to another noble and moved to Constantinople, while John XII supposedly brought prostitutes into the papal palace.

Then there was the legend of Pope Joan, who may be confused with John VIII. Supposedly, she was a scholarly woman who got elected pope without anyone realizing her gender. That was until she went into labor during mass and was subsequently killed and deposed. Whatever the truth of this story, after this, popes were crowned on a chair with a hole in the seat to confirm they were men.

Monastic sign Language

The refectory where monks would gather to eat in silence

Since monks were supposed to refrain from speaking during mealtime while a comrade read scripture aloud to them, they developed a sophisticated sign language to communicate their needs while eating. These are taken from *Monasteriales Indicia*, Book with 127 signs used in Anglo Saxon monasteries.

(8.53) If you need a dish, raise up one hand and spread your fingers.

57. (8.54) When you would have a loaf of bread, set your two thumbs together and your two forefingers one against the other.

58. (8.55) If you need a knife, cut with one finger over the other as if carving.

59. (8.56) If you need a spoon, move your hand as if you were eating with a spoon.

63. (9.60) The sign of porridge is to move your fist back and forth as if stirring porridge.

64. (9.61) When you would like pepper, shake with one forefinger over the other.

67. (10.64) When you would like cheese, set your two hands flat together, as if pressing.

68. (10.65) If you want butter or fat, stroke with your three fingers on the inside of your hand.

69. (10.66) If you would like milk, stroke your left finger with your right hand as if you were milking.

70. (10.67) If you need eggs, scrape with your finger up on your left thumb.

71. (10.68) When you would like salt, bring down your hand with three fingers together, as if you were salting something.

72. (10.69) The sign of honey is to set your finger on your tongue.

73. (11.70) When you would like fish, move your hand back and forth the way a fish moves its tail, when it swims.

(7.48) When you would have a whip, move your fist back and forth as we described before, and raise up your two fingers.

The Arsenal of Papal Weapons

Jan Hus being excommunicated as a heretic

While at first glance the popes would seem to be at a disadvantage in their struggles against powerful secular rulers, they had allies who could carry on the fight in return for blessings and the hope of confiscating the papal enemies' lands. They also had a formidable arsenal of spiritual weapons, two in particular: excommunication and the interdict.

Excommunication cut its victim off from the Church and even society itself. The excommunicant and everything about him were

cursed: his clothes, food, air, etc. In addition his subjects were absolved of their oaths of loyalty to the ruler and didn't have to obey him

Interdicts stopped church services for laity in a whole region by "bell, book, & candle." In fact, often the first sign that something was wrong was the failure of the church bells to ring at regular times to signal when it was time for prayers (similar to the muezzin's call to prayer in Islam.) During an interdict, masses were only held for other clergy. There were no marriages performed or burials on consecrated ground, leading to the fear that those who died under interdict would go to hell. Therefore, an interdict was a weapon that could scare and anger people and put pressure on a ruler to give in to the pope.

Declaring a crusade against the pope's enemies was another way to stir up the public, since it promised forgiveness of sins for those who participated and gave them the right to confiscate the enemy's property.

However, the popes had to be careful in using these spiritual weapons against worldly, especially Christian, enemies, since their impact tended to wear out with repeated use as people became increasingly skeptical about their legitimacy. Besides, two could play that game and the emperor could set up anti-popes who claimed to be the truly legitimate popes, being elected by the bishops (or cardinals after 1055) who owed their offices to the emperor who typically appointed them before the Investiture Struggle.

Returning corruption and renewed Redemption: St. Francis of Assisi

St. Francis preaching to a flock of birds

As the Church's wealth and power increased, various corrupt practices worked their way back into use (or never went away) among some clergy. For example, Bishop Matthew of Toul, although excommunicated for eight years, murdered his replacement and plundered church lands. The bishop of Parma even refused last rites from the church he led and supposedly had believed in. Another clergyman rigged up a crucifix that made Jesus move on the cross. Some bishops were barely literate and could not pronounce, let alone understand the Latin scripture they were reading their followers. Not surprisingly, standards fell among the lower clergy. One study indicated that the average priest knew only four of the Ten Commandments. Meanwhile, peasants were crumbling communion wafers on their cabbages as some sort of magical potion/insecticide.

But just as things seemed to be at their lowest, someone would rise from the ranks of the Church to revive it spiritually. In the early 1200s, that role was especially played by St. Francis of Assisi.

St Francis was the son of a wealthy merchant who grew up rich and spoiled. He fought in Assisi's army against neighboring Perugia and in 1204 joined Innocent III's army. At that point, he fell ill with a fever. While recovering, he heard a voice asking him: *"Why do you desert the lord for the servant, the prince for his vassal?"* Taking this as a sign from God, he left the army and went home to devote his life to God.

Francis especially devoted his life to helping the poor, even giving them the clothes off his back.

Once after shrinking back in revulsion at the sight of a leper, he repented and returned to give him money and even kiss his hand to show his humility before God.

His father was furious with how Francis had handled his money, and summoned him before the bishop. Declaring he was now only a son of God, Francis returned all his property and even his clothes to his father who took them and left. (Throughout his life, Francis' followers had a hard time keeping him in clothes, because whenever he saw a beggar, he would literally give him the clothes off his own back.)

Francis then went to rebuild an old chapel with his own hands. Claiming himself now married to Lady Poverty he resolved to obey the Gospels & preach the kingdom of Heaven and gospel of poverty, begging for food from door to door.

Among other things, because of his love of animals, Francis would become the patron saint of animals. He would buy game birds in the market to set them free. In return, birds would supposedly perch on his hand and listen to him preach. At one point he petitioned the emperor Frederick II to ban hunting animals for sport. Another time, when someone was about to put out a candle, Francis stopped him, saying the candle might not want to be put out.

Francis himself was never ordained as a priest, but he would preach to the common people in the vernacular (common language instead of Latin which people no longer understood), while leaving ordained followers to administer church sacraments. Although not an ordained priest, Francis still convinced Pope Innocent III to formally ordain the Franciscans as a mendicant order that went out to preach (as opposed to a cloistered order whose monks generally stayed in their monasteries).

Supposedly, Francis even went on crusade, not to kill Muslims but convert them. One night he slipped through the lines and showed up in the sultan's tent to preach to him about Jesus' love. Although he didn't convert, the sultan was impressed with this simple and kindly man and had him escorted safely back to the Christian camp.

In addition to preaching in the common language to make Jesus' message more accessible to the mass of people, Francis also loved to sing as a way of praising God, serving as a sort of glee club for Jesus. Therefore, when terminally ill and told that he was about to die, he sang a song in praise of death.

Francis and the order he founded were just what the Church needed in an age of growing material prosperity. Franciscan friars wandered far and wide, preaching to the common people while owning nothing beyond their plain brown robes and begging bowls. Unfortunately, as before, most people weren't ready to devote their lives to such a severe discipline, but many wanted to donate to the Franciscans in order to save their own souls. However, the Franciscans lived by a strict code of poverty and could not accept such donations, until someone cleverly drew the distinction between *owning* property and *stewarding* (taking care of) it for God.

Thus the cycle of corruption and spiritual revival in the Church started again, so that by 1500 the Franciscans were parodied as being fat and corrupt drunkards. That parody especially survived in the form of Friar Tuck of Robin Hood fame and whose name graces the entrance to a chain of liquor stores.

Luckily for the Church, other reformers, such as St. Ignatius Loyola and St. Xavier would come along to pick up the banner of spiritual reform that St. Francis had so boldly waved in his own time.

EUROPE RESURGENT: THE CRUSADES (1095-1291)

*"...But these were small matters compared to what happened at the temple of Solomon, a place where religious services are ordinarily chanted. What happened there? If I tell the truth, it will exceed your powers of belief. So let it suffice to say this much at least, that in the temple and portico of Solomon, men rode in blood up to their knees and bridle reins. Indeed, it was a just and splendid judgment of God, that this place should be filled with the blood of the unbelievers, when it had suffered so long from their blasphemies."--
Foucher de Chartres*

The First Crusade (1095-99). The modern reader (both Christian and non-Christian) is justifiably shocked at how medieval Christians such as Foucher de Chartres exulted in the wholesale butchery that took place in Jerusalem, the holiest city of Christianity, to end the religious war known as the First Crusade. However, that description expresses quite well not just the rough edge of medieval Christian faith, but also the power and energy that, for nearly two centuries, drove Europeans to launch the Crusades in order to conquer and hold Palestine. There were several reasons for the Crusades happening when they did.

First of all, there was the expanding power of Western Europe in the eleventh century. More settled conditions plus better agricultural techniques helped trigger population expansion that created large numbers of landless younger sons of nobles. Adding to these pressures was a series of bad harvests providing an even greater incentive to find land elsewhere. While the Crusades were the most dramatic and publicized example of Europe's expanding frontiers, there was similar expansion by Spanish Christians in Spain, by the Normans in Southern Italy and Sicily, and by the Germans in Eastern Europe.

The most immediate reason centered on events in the Middle East. In the eleventh century, a new people, the Seljuk Turks, replaced the Arabs as

the dominant power in the Islamic world, overrunning most of Asia Minor after crushing the Byzantine army at Manzikert (1071) and seizing Palestine from the Shiite Fatimids of Egypt. These conquests led to pleas to the West for help, both from Christian pilgrims to Palestine who suffered from mistreatment at the hands of the Turks and from the Byzantine emperor, Alexius I, who just wanted mercenaries with which he could reconquer Asia Minor. As an added enticement, Alexius held out the possibility of reuniting the Greek Orthodox and Roman Catholic Churches, which had been split since the schism of 1054.

The rising power of the Church at this time was another factor leading to the Crusades. This created a rising tide of piety in Western Europe that expressed itself in pilgrimages to Palestine before the Turks seized it, and adapted itself to a holy war (crusade) after the Turkish conquest. This rising tide of piety was part of a broader movement for Church reform led by the popes that had caused the Investiture Struggle with the German emperors over control of the election of Church officials. Both the reunification of the Catholic Church with Byzantium and the recovery of Jerusalem fit into the larger ambitions of Pope Urban II. If the pope could lead all of Christendom in a crusade to recover the Holy Land (Palestine), then his moral authority would far surpass that of the German Emperor. Therefore, in 1095, at the French town of Clermont, Pope Urban II preached the First Crusade (from the Latin word, *crux*, for cross) to liberate the Holy Land from the Turks. Apparently his speech struck a nerve, because thousands enthusiastically "took the cross" (i.e., vowed to go on crusade).

This raises the question of what spurred the rank and file of Europe to undertake such a long and dangerous journey. Two main factors present themselves: piety and poverty. Piety should never be downplayed in the Middle Ages, although the nature of medieval piety may have been somewhat different from our own concept of it. Crusaders went to the Holy Land believing that such a journey and the killing of non-Christians in defense of the faith would earn them forgiveness for their sins. Poverty and greed also played their role. As we have seen, Europe's expanding population created a large number of landless

younger sons of nobles. Going on crusade offered them both the opportunity to win such lands and forgiveness for their sins as well. No wonder so many of them decided to undertake such a long and dangerous enterprise.

Most of those who went were nobles who needed time to get supplies for their journey and set their personal affairs in order before leaving. Therefore the departure of the First Crusade was set for August 1096 from Constantinople. This would also give the Byzantines time to prepare supplies along the line of march.

However, there were also many desperately poor peasants who had no substantial affairs to set in order. Therefore, they just set off for the Holy Land without making any plans or provisions for the march. These undisciplined mobs, known collectively as the Peasants' Crusade, gained followers and momentum in each village through which they passed. Their growing numbers also created ever mounting supply problems that often erupted into violence as they turned to pillaging for food. Such violence was often turned against local Jews, since they were non-Christian and this was a "holy war" to begin with. As a result, thousands of Jews were either killed or forced to flee their homes.

However, the Jews were not the only ones upset by these peasant groups, and local populations and rulers would often turn against these unwelcome intruders. For example, three waves of peasants who went through Hungary were each destroyed by the Hungarians who were tired of their plundering.

Those who made it to the Byzantine Empire fared no better. Many were picked off on their foraging raids by Byzantine cavalry. The rest were quickly ferried across to Asia Minor to prevent further trouble in Constantinople. Not trusting the Byzantines, this undisciplined mob ignored Alexius' advice to stay by the coast and Byzantine

support. As a result, the Turks annihilated all but a few of them. When the main body of crusaders arrived, the few surviving peasants they met blamed their fate on Byzantine treachery. Relations between Byzantines & crusaders were already being poisoned.

Soon after landing in Asia Minor, the crusaders came upon the remains of the Peasants Crusade massacred by the Turks, a grim warning of hardships ahead.

The more organized and disciplined crusading knights and nobles made their way to Constantinople in isolated groups. This allowed the emperor to deal with them singly, impressing them with his collection of relics and mechanical wonders and then extracting an oath from them to turn over any lands formerly held by the Byzantines. He would then shuttle them across to Asia Minor in time to meet the next group of crusaders arriving in Constantinople and repeat the process. These measures did help Alexius recover part of Asia Minor, notably the city of Nicaea, but they also added to growing tensions with the Crusaders who felt they were the victims of Byzantine trickery.

On the eve of the final assault, the Turks secretly surrendered Nicaea to the Byzantines rather than face massacre by the Western "barbarians". This especially irked the Crusaders who had borne the brunt of the siege, & soured their relations with the Byzantines.

The crusaders saw their first serious fighting in Asia Minor. Helped by both the turmoil caused by the Assassins' murder of Malik Shah and the Turks' expectation that these European knights would be as easy a prey as the Peasants' Crusade had been, the crusaders' heavily armored shock cavalry defeated the Turks in their first major encounter. The crusaders themselves were frustrated by the Turks' mobile hit and run tactics that made it hard to win a decisive victory over them. Despite this, the intense heat, and even poisoned wells, the crusaders fought their way across Asia Minor.

While the rest of the crusaders pressed into Syria, one of their leaders, Baldwin, carved out his own state around the city of Edessa using only 80 knights and some skillful diplomacy and intrigue. Naturally, this spurred the ambitions of other crusaders, in particular a Norman knight named Bohemond who had his eyes set on Antioch, one of Syria's premier cities. Antioch fell after a long grueling siege, thanks largely to the intrigues of Bohemond who then claimed the city as his own. This was the second of the crusader states to be founded as well as the source of a good deal of jealousy and quarrelling among the various crusader leaders.

Crossing the Anti-Taurus Mountains with their treacherous passes was another major challenge for the crusaders, especially since it was during the rainy season. Supposedly more crusaders & pack animals perished here than during any other part of the journey.

The eight-month siege and stay at Antioch had decimated the Christian army through disease, hunger, and battles against various Muslim armies

sent to relieve Antioch. Add to this the constant bickering between its leaders and the polyglot mixture of French, English, Germans, and Italians making up the army, and the chances of continued success did not look good. However, the rank and file in the army insisted on putting aside their quarrels and marching on Jerusalem. Finally, in June 1099, with an army of only 15,000 men, they reached their long sought goal, Jerusalem.

The crusaders endured desert heat and shortages of food and water while besieging Jerusalem. They also faced the threat of a large Egyptian army coming to relieve the city. Luckily, an Italian fleet arrived at the harbor of Jaffa, bringing the crusaders supplies and timber for siege engines. After doing penance by marching barefoot in the desert heat around Jerusalem, the crusaders launched an assault that broke into the city on July 15. What ensued was one of the worst massacres in history, spurred on by religious frenzy combined with frustration from the hardships of the last three years. Foucher de Chartres' graphic description at the top of this reading shows how the crusaders used religion to justify this ghastly event. The success of the First Crusade was a remarkable feat, but it was stained with the blood of thousands of innocent Muslims and Jews.

The Kingdom of Jerusalem (1099-1187).

Despite their incredible victory, the crusaders had much going against them. First of all, they were surrounded and outnumbered by hostile Muslim states that eventually learned to unite against the Christian invaders. Secondly, since they were so far from their home base in Europe and many of the original number went back home after the conquest of Jerusalem, the remaining crusaders suffered a chronic manpower shortage, leaving them spread thinly across Syria and Palestine.

Third there was a growing cultural gap between the crusaders who stayed behind in the Holy Land and any newcomers who did arrive from Europe. They were shocked to find that after a number of years in the Near East, the original crusaders had adapted to local ways. Their clothes and houses resembled those of the Muslims. Some even kept harems with veiled women wearing makeup. More surprising yet, they set aside chapels in their churches where their Muslim neighbors could worship. Even their wars were fought in the more sophisticated local method of small local raids interrupted by truces with the Muslims. Nothing daunted, these newcomers, who had come all this way with the purpose of killing Muslims, would often break the truces, attack the Muslims, and then go home, leaving the crusaders in Palestine to bear the brunt of Muslim reprisals.

A fourth problem stemmed from the feudal system that the crusaders transplanted from Europe. Instead of one unified kingdom, they founded four separate states: the kingdom of Jerusalem and the counties of Edessa, Antioch, and Tripoli. This prevented the cooperation and unity of purpose needed against the surrounding Muslim enemies. Compounding this into a virtually hopeless situation was the further fragmentation of these states into individual baronies and fiefs.

Finally, the presence of the Italian city-states proved to be a mixed blessing. While they did provide a vital lifeline to Europe along with valuable naval support in taking the coastal cities of Palestine, this was all done for a price: the establishment of independent quarters in the coastal cities that they had helped take. This could be somewhat disruptive, since at times they might not cooperate with the crusaders in wars that could hurt their trade and business. At other times, two Italian cities might go to war with each other and the fighting would spread to those cities quarters in various crusader cities. In addition, Italian merchants also controlled much of the trade of Palestine and Syria, depriving the crusaders of much needed revenues.

Despite all these hardships, the crusader states did remarkably well, even expanding their territory in the early decades of the 1100's. Europe was still

enthusiastic about the crusaders' success and kept a constant (if barely adequate) stream of reinforcements going to the Holy Land. However, as the surrounding Muslim states unified against the common enemy, the tide started to turn.

The first crusader state to fall was Edessa in 1144, which promptly triggered the Second Crusade to recover it. This crusade, led by Louis VII of France and Conrad III of Germany, tried to follow the route taken by the First Crusade. However, the heat of Asia Minor and severe supply problems decimated the crusaders' army, which was then beaten near Damascus, leaving Edessa in Muslim hands for good.

The next forty years saw Egypt and Syria become unified in a strong Muslim state under the skillful leadership of Salah-a-din. Gradually, he tightened the noose around the beleaguered crusader states and finally destroyed the crusader forces at the Battle of Hattin in 1187. Jerusalem and most of the coastal cities of Palestine and Syria soon fell into Saladin's hands.

This brought on a series of crusades that failed to take Jerusalem or hold it for any substantial time. The third Crusade (1187-92), led by the famous warrior king of England, Richard "the Lionhearted", managed to take the coastal city of Acre after a prolonged siege. However, despite a march down the coast and various exploits, including a hard fought victory against Salah-a-din at Arsuf, Richard failed to take Jerusalem. Salah-a-din did grant Christian pilgrims free access to the holy city in order to worship, something he would have been willing to do anyway.

Later crusades tended to stray further and further from their goal of Jerusalem. For example, the Fourth Crusade (1202-4) was diverted by the Venetians to Constantinople, partly to cover the cost of transporting the crusaders, and partly because of growing tensions with the Byzantines over the growing Italian stranglehold on Byzantine trade. In 1204 the Venetians and crusaders stormed and mercilessly sacked Constantinople.

Besides never reaching Palestine, the Fourth Crusade set in motion the final decline of the

Byzantine Empire and deprived the crusaders of a potentially valuable ally. Relations between the Byzantines and Western Europe, which had been deteriorating for some time, grew that much worse as a result of the Fourth Crusade.

The Fifth Crusade (1228-9), led by Frederick II of Germany, did manage to negotiate the surrender of Jerusalem, but without fortifications. As a result it fell back into Muslim hands soon after Frederick returned home. The Sixth Crusade (1248-50) under Louis IX of France (Saint Louis) was directed against Egypt in the hope of being able to trade it for Palestine. The strategy would have worked except that Louis refused to negotiate with the Muslims when they were ready to give in. Then the Nile flooded, disease set in, and the entire French army was captured and forced to ransom itself from captivity. The Seventh Crusade (1270), also led by Louis IX, was directed even further afield against Tunis in North Africa. The idea was to cut off Muslim trade in the Mediterranean between Tunis and Sicily (which was held by Louis' shrewder and more practical brother, Charles of Anjou). Once again, disease did its work, this time claiming Louis, who died with the words "Jerusalem, Jerusalem" on his lips.

After this, interest in the crusades fizzled out for a couple of reasons. For one thing, Europe had changed dramatically in the 200 years since Urban II had preached the First Crusade. The rise of towns and a money economy had raised Europe's standard of living tremendously and given its people something to get interested in besides holy wars in distant lands. Also, the popes had gotten into the habit of declaring crusades against heretics in Europe (e.g., the Albigensians in France) and their mortal enemies, the German emperors. This cheapened and tarnished the image of the crusade and cost it a good deal of support.

Meanwhile, the crusader states huddled along the coast of Palestine were gradually being worn down by Muslim pressure. A brief hope of delivery seemed to present itself with the Mongols, who shattered one Muslim army after another in their rampage across Asia. However, in the Battle of Ayn Jalut (1260), the Mameluke sultan of Egypt, Baibars, crushed the Mongols and

stopped their advance once and for all. This also sealed the fate of the crusaders who had encouraged the Mongols. In 1291, the last of their strongholds, Acre, fell after a desperate siege. For all intents and purposes, the age of Crusades was over.

Despite their failure, the crusades had important results. For one thing, they opened Europeans' eyes to a broader world beyond Europe, stirring interest in and a bit more tolerance of other cultures. In particular, an influx of Arab texts and translations of classical Greek and Roman literature created a more secular outlook that helped lead to the Italian Renaissance in the 1400's. The Arabs passed on knowledge in a wide array of topics ranging from math, astronomy, and geography to such techniques as papermaking and the refining of alcohol and sugar (both of which are Arabic words). On a more basic level, the Crusades stimulated an increased desire for luxury goods from the East. When they lost control of these trade routes to the Turks, they embarked upon a series of voyages of exploration in search of shorter and cheaper routes to get those luxuries. In the process, Africa was circumnavigated, Asia was more thoroughly mapped, and the Pacific Ocean, the Americas, and Australia were discovered. Thus, the Crusades, by helping lead to the Renaissance and Age of Exploration, were instrumental in opening the way to the modern world.

For the Arab world, the Crusades had less positive results. True, the Muslims ultimately won, but at a heavy price. Besides the human and material cost, there was also the psychological factor. Since c.1000 C.E., the Arab world had been assaulted by Turks, Crusaders, and Mongols. These successive invasions generated the feeling that Arabs must harden their attitude toward other cultures in order to preserve their own. In succeeding centuries, as Western Europe created its own high civilization, which has largely dominated the globe since the 1800's, many Arabs have resisted the pressure to adapt aspects of that culture to benefit their own, an attitude that has often put them at a disadvantage in the modern world. The struggle of whether or not to modernize and make compromises with Western culture still divides the Arab world today.

Antioch (Oct. 1097- Jan. 1099)

In October, 1097, the Crusaders reached Antioch in Syria, the seat of one of the five original patriarchates of the Church. It was a formidable city, having 400 towers, open ground inside its walls for growing food, and a citadel 1000 feet above the rest of the town. However they had to take it in order to secure the road to Jerusalem.

The crusaders couldn't even surround the city, and had to settle for guarding its gates. A Byzantine fleet, most likely manned by Anglo-Saxons in Alexius' pay, had taken Antioch's port city, St. Symeon. However, any supply convoys sent from there to the crusaders besieging Antioch faced the constant threat of being raided.

With winter came rain, food shortages, and disease. Many deserted the crusader camp, including Peter the Hermit (who was caught and brought back) and the Byzantine general, Tacticius, who feared the crusaders would blame him for their troubles. Earth tremors and the Aurora Borealis further demoralized the besiegers.

When Bohemond of Taranto & Robert of Flanders left on a foraging expedition, they ran into a relief army from Damascus which they turned back after a hard fought battle. However, they returned to Antioch empty-handed and found their comrades had barely defeated an attack by the city garrison.

Soon afterward, news came of another powerful army, this one from Aleppo, coming to relieve Antioch. With only 700 horses left in the army, those knights still with mounts ambushed and defeated this new threat.

In early 1098, Baldwin, younger brother of Godfrey of Lorraine, left the main army besieging Antioch and took 80 knights to Edessa on the Euphrates River. He was welcomed there as a liberator from the Turks by the Christian Armenian population and

adopted by the local leader whom he soon overthrew, seizing power for himself.

However, Baldwin was popular with the Armenians, since he had freed them from the Turks & used them in his government. Edessa would serve as a useful Crusader outpost until its fall in 1144. However, as an independent ruler with a large treasury, Baldwin drew many knights away from the Crusaders' army into his service, while inspiring others, most notably Bohemond, to want their own states.

In June, 1098, the siege of Antioch was still dragging on when news came of the approach of yet another relief army, this time led by Kerbogha of Mosul. The crusaders had to take Antioch to avoid being caught between Kerbogha and the city garrison.

Meanwhile, Bohemond had established contact with an officer of the garrison willing to betray the city. Reluctantly, the other crusaders agreed to let Bohemond have the city if he could deliver it to them.

On June 3, 1098, the Crusaders gained entry to the city and proceeded to massacre the population.

Inhabitants of Antioch escape over the city walls to avoid massacre by the Crusaders when they took the city.

Two days later, Kerbogha arrived with the largest army the Crusaders had encountered yet.

The besiegers had become the besieged.

Adding to their misery, the corpses from the massacre were rotting in the hot summer sun and threatening to bring epidemic.

The deserters met the Byzantine emperor Alexius coming with a relief force. However, after the deserters convinced him that the situation in Antioch was hopeless, he turned back, which added further to the distrust developing between crusaders and Byzantines.

Meanwhile, the situation in Antioch grew more desperate by the day. Food was so scarce that one egg cost 2 gold bezants, while a chicken cost 15.

At this point, as luck would have it, an unknown monk named Peter Bartholomew was inspired by a dream to dig beneath a church in Antioch and find what he believed to be the holy lance-head that pierced Christ's side on the Cross.

While the leaders of the crusade were skeptical about Peter Bartholomew's find, the rank and file believed in it.

Inspired by this relic at the head of their ranks, the Crusaders emerged to meet the Muslim army and routed it in a battle which turned into a massacre when Kerbogha's emirs deserted him.

Over the next several months, the crusaders consolidated their hold on the territory by taking neighboring strongholds. Meanwhile, squabbling continued over control of Antioch. A typhoid epidemic that killed the papal legate, Adhemar, eliminated the one peacemaker who had been able to keep the crusade with its various nationalities together.

Finally, the rank and file, anxious to continue on to Jerusalem, threatened to destroy Antioch's walls if the princes couldn't patch up their quarrels.

Jerusalem (June-July 1099)

In January, 1099, Bohemond got his coveted prize, Antioch, and the rest of the crusaders proceeded on to Jerusalem.

With Kerbogha of Mosul's power broken, the way lay open to the holy city with virtually no opposition.

Finally, in June 1099, with an army of only 15,000 men, they reached their long sought goal, Jerusalem.

Jerusalem was held by a large garrison loyal to Fatimid Egypt. Initial assaults on the city failed, while food supplies dwindled to critical levels. Water was an even greater problem, the garrison having poisoned all but one of the surrounding wells and springs. And that spring was directly beneath the city walls manned by a hostile garrison.

Luckily for the crusaders, six ships from Pisa sailed into the deserted harbor of Jaffa with materials for building siege engines.

The approach of a powerful relief army from Egypt forced the crusaders to hurry preparations for the final assault on Jerusalem.

However, the crusaders, their ranks reduced to a fraction of those who had started out from Constantinople, marched barefoot in penance around Jerusalem before launching what would prove to be the final and decisive assault on the city.

The final assault started on July 13. After two days, one of their siege towers finally gained a foothold on the walls. Panic set in and resistance collapsed. The ensuing massacre of Muslims and Jews was one of the great atrocities in history, killing an estimated 40-60,000 people.

After the massacre, the victorious Crusaders gathered in the Church of the Holy Sepulchre to give thanks for their victory.

Three weeks later, news of the fall of Jerusalem, reached Rome.

Unfortunately, Pope Urban II, who had started the crusading movement, had died one week earlier.

The Kingdom of Jerusalem (1099-1187)

The victorious crusaders elected one of their number, Baldwin, as the king of Jerusalem. Most of them then went home, leaving Baldwin with an army of only 300 knights.

The remaining crusaders proceeded to consolidate their hold on the Holy Land by taking the coastal ports, largely with naval support from Italian city-states such as Genoa, Pisa, and Venice.

Unfortunately, the massacres didn't stop, as Muslims and Jews were put to the sword in various cities, such as the seaport, Caesarea.

In the years that followed, Baldwin at the head of tiny Christian armies would score several remarkable victories over relief armies launched from Egypt. From these victories came an aura of invincibility that gave crusaders a huge psychological edge over their Muslim foes for decades.

However, despite their incredible victory, the crusaders had much going against them. First of all, they were surrounded and outnumbered by hostile Muslim states that eventually learned to unite against the Christian invaders.

Secondly, since they were so far from their home base in Europe and many of the original number went back home after the conquest of Jerusalem, the remaining crusaders suffered a chronic manpower shortage, leaving them spread thinly across Syria and Palestine.

One way to fill their ranks was to hire local mercenaries, known as Turcoples, whose style of warfare was suited to combat the mobile hit-and-run tactics of their neighbors. Another way to cope was to fortify any settlements against the sudden raids that were a hallmark of Middle Eastern warfare.

Krak des Chevaliers below), in present day Syria, is probably the best surviving example of the chain of castles the Crusaders built to defend their conquests. Such fortresses maximized the value of the very limited manpower the Crusaders had for defending their holdings. The techniques for building such massive stone fortifications, learned from the Byzantines and Muslims, became the basis for what we associate with medieval castles.

Much of the crusader states' military strength came from two military orders, the Hospitallers and the Templars.

The Templars had originally stayed behind in Palestine after the First Crusade to tend the Church of the Holy Sepulchre. Soon they assumed the military role of protecting pilgrims in the Holy Land which soon expanded to fighting anywhere for the faith. They were given the al-Aqsa mosque which was believed to be the site of the Temple of Solomon, thus giving them their name. The pope officially ordained them as a military order in 1120 and as a religious order in 1129.

Similarly, the Hospitallers started out tending the sick in a hospital in the Holy Land and soon assumed military duties.

Both orders were respected for their discipline and training. In addition to combat skills, they were expected to maintain monastic purity and chastity.

Besides attracting recruits for the holy war, the Templars and Hospitallers received generous donations. In the early 1300s' Philip IV of France brought trumped up charges of heresy against the Templars so he could confiscate their wealth. Although the charges were never proven, the pope had the order dissolved and their lands given to the Hospitallers, then known as the Knights of St. John.

Since they could attract a more steady supply of recruits from Europe, the Templars took over more and more castles from nobles no longer able to maintain and garrison them. As a result, they became an increasingly vital part of the defense of Palestine. This translated into political influence and a sometimes bitter rivalry between the two orders.

A third problem the crusader states faced was a growing cultural gap between the crusaders who stayed behind in the Holy Land and any newcomers who did arrive from Europe.

These newcomers were shocked to find that after a number of years in the Near East, the original crusaders had adapted to local ways. Their clothes and houses resembled those of the Muslims. Some even kept harems with veiled women wearing makeup. More surprising yet, they set aside chapels in their churches where their Muslim neighbors could worship.

Even their wars were fought in the more sophisticated local method of small local raids interrupted by truces with the Muslims. Nothing daunted, these newcomers, who had come all this way with the purpose of killing Muslims, would often break the truces, attack

the Muslims, and then go home, leaving the crusaders in Palestine to bear the brunt of Muslim reprisals.

Through Arab eyes

Arab medicine was probably the most advanced of its day, relying largely on herbal cures, distilled natural oils, and common sense. Likewise, Arab surgeons were highly accomplished. By contrast, European medical practices were crude and even shocking to the Arabs. Even Christians learned to prefer Arab doctors to their own.*

“When they came near us I saw that the man in the middle had been struck across the center of his face by a Crusader’s sword...One half of his face was so loose that it hung over his chest and between the two halves was a gap almost the width of a hand span...The surgeon sewed his face and treated it. The sides stuck together and the man recovered.”--Memoirs of Usama ibn Munqidh

Contrast the treatments given first by an Arab and then a Christian doctor to cure a knight with an abscess on his leg and a woman suffering from tuberculosis.

First, the Arab doctor prepared a plaster for the knight, causing the swelling to open up and improved. For the woman he prescribed a better diet for the woman and she improved as well.

Along came the Frankish (European) doctor who objected, *"This man does not know how to care for them"* After which he asked the knight: *"Which do you prefer, to live with one leg or die with two?"*

Thereupon he had another knight with a battle-axe chop off the infected leg, causing the patient to die right away.

Concerning the woman, he said: *"She has a demon in her head who has fallen love with her. Cut her hair"* After they cut her hair & returned her to her diet, she got worse, leading the Frankish doctor to declare: *"The devil himself must have entered her head"*

Whereupon he cut a cross-shaped incision in her skull and rubbed salt into it, causing her to die right away.

The Arabs had other choice words concerning the Franj (Franks):

"The Franj (I.e., Franks) have no sense of honour. If one of them is walking in the street with his wife and encounters another man, that man will take his wife's hand & draw her aside and speak to her, while the husband stands waiting for them to finish their conversation. If it lasts too long, he will leave her with her interlocutor & go off! Imagine this contradiction! These people possess neither jealousy nor honour, whereas they are so courageous. Courage, however, comes only from one's sense of honour and from contempt for that which is evil!"

"When I was visiting Jerusalem, I used to go to al-Aqsa mosque, where my Templar friends were staying. Along one side of the building was a small oratory in which the Franj had set up a church. The Templars placed this spot at my disposal that I might say my prayers. One day I entered, said 'Allahu akbar', and was about to begin my prayer, when a man, a Franj, threw himself upon me, grabbed me, and turned me toward the east, saying, 'Thus do we pray'. The Templars rushed forward and led him away. I then set myself to prayer once more, but this same man, seizing upon a moment of inattention, threw himself upon me yet again, turned my face to the east, and repeated once more, 'Thus do we pray.' Once again the Templars intervened, led him away, and apologized to me saying, 'He is a foreigner. He has just arrived from the land of the Franj and he has never seen anyone pray without turning to face east.' I answered that I had prayed

enough and left, stunned by the behavior of this demon who had been so enraged at seeing me pray while facing the direction of Mecca."

A fourth problem stemmed from the feudal system that the crusaders transplanted from Europe. Instead of one unified kingdom, they founded four separate states: the kingdom of Jerusalem and the counties of Edessa, Antioch, and Tripoli. This often hampered the cooperation and unity of purpose needed against the surrounding Muslim enemies.

Compounding this into a virtually hopeless situation was the further fragmentation of these states into individual baronies and fiefs that were often just as hard to control.

For example, it was the behavior of one baron, Reynald de Chatillon, who raided Muslim caravans and harassed pilgrims on their way to Mecca, that aroused the full wrath of the Muslim leader, Saladin, against the crusader states in 1187, leading eventually to the disastrous campaign of Hattin and the fall of Jerusalem.

Finally, the presence of the Italian city-states proved a mixed blessing. While they did provide a vital lifeline to Europe & valuable naval support in taking the coastal cities of Palestine, they did this for a price: the establishment of independent quarters in the coastal cities that they had helped take. However, at times they might not cooperate with the crusaders in wars that could hurt their trade and business. At other times, two Italian cities might go to war with each other and the fighting would spread throughout various crusader cities. In addition, Italian merchants also controlled much of the trade of Palestine and Syria, depriving the crusaders of much needed revenues.

Although stripped of almost all its armed forces, those left in Jerusalem valiantly withstood the siege by Saladin's forces, acutely aware of the massacre their predecessors had inflicted in 1099. However, Saladin generously let the Christians buy their freedom, even releasing those who too poor to pay the ransom.

The Third Crusade (1189-92)

Even with the loss of Jerusalem, the crusaders still managed to hang onto Antioch, Tripoli, and Tyre. While the pope was calling for a new crusade in Europe, the remnants of crusader forces in Palestine gathered at Tyre and began to regain their lost lands.

The Third Crusade is known as the Crusade of kings, since three monarchs took the cross: Philip II of France, Richard I of England, and the Hohenstauffen emperor of Germany, Frederick I Barbarossa. However, Frederick, retracing the old land route taken by the first two Crusades, drowned while crossing a river, and his army turned back.

The main focal point of crusader efforts was the port city, Acre, around which an epic siege developed. While the crusaders besieged the city, Saladin in essence besieged them in an effort to relieve the city. However, the arrival of crusaders from Europe expanded the Christian forces enough to keep Saladin at bay.

Probably the most famous crusader of all, Richard I of England, known as Richard the Lionheart, took part in the Third Crusade. It was his presence that especially breathed new life into the siege of Acre.

The crusaders' siege of Acre was noted, among other things, for its siege engines such as a ladder named The Cat and trebuchets with such names as God's Own Sling and The Bad Neighbor. It was these machines as much as anything else that brought about the fall of Acre in 1191. It would serve as the capital of the crusader kingdom until its fall almost exactly one century later in 1290.

Islam Resurgent (1144-87)

In 1144, Edessa became the first crusader state to be reclaimed by the Muslims. This promptly triggered the Second Crusade to recover it. This crusade, led by Louis VII of France and Conrad III of Germany, tried to follow the land route taken by the First Crusade. However, the heat of Asia Minor and severe supply problems decimated the crusaders' army, which was then beaten near Damascus.

The crusaders would never recover Edessa.

The noose was starting to tighten.

The next forty years would see Egypt and Syria become unified in a strong Muslim state under the skillful leadership of Salah-a-din (AKA Saladin)

Gradually, Saladin tightened the noose around the beleaguered crusader states. Finally, he trapped and destroyed practically the entire armed forces of the Kingdom of Jerusalem at the Battle of Hattin in 1187.

Most of the Knights Templar and Hospitaller fell fighting at Hattin. Those who surrendered were executed by Saladin in an uncharacteristic example of brutality.

The defeat at Hattin left Christian strongholds throughout Palestine almost completely stripped of their garrisons, allowing Saladin to quickly overrun one Crusader castle after another as he marched toward his ultimate goal, Jerusalem.

Richard may have been known as a great warrior, but not a kind one, as seen in the episode where he had 5000 Muslims taken prisoner at Acre executed by beheading.

After the fall of Acre, Richard led the crusaders down the coast, taking more ports and gaining great glory for his exploits as a warrior. Saladin attacked the crusaders along the coastal road at Arsuf. Although the Muslim horse archers were taking a horrible toll on the crusaders' war horses, Richard held his army in check to avoid attacking prematurely and falling into a trap.

Suddenly, the hard-pressed Hospitalers charged setting the whole crusader army into motion. The suddenness of this charge took Saladin's army by surprise and routed it.

Despite his famous exploits, Richard was never able to retake Jerusalem, and had to return to Europe when his fellow crusader, Philip II of France, who had gone home early, attacked Richard's lands in France.

However, Salah-a-din did grant Christian pilgrims free access to the holy city in order to worship, something he would have been willing to do anyway.

The Crossbow was and extremely powerful bow used by the Crusaders and European armies in general. While slow to load, its power and range were such that the Papacy unsuccessfully tried to outlaw its use in the 1100s as inhumane, especially for nobles, since commoners armed with it could defend themselves on the battlefield. However, the pope and other Christians had no qualms about using this weapon on Muslims.

The Fourth Crusade: A Crusade Gone Astray (1202-1204)

In 1202, Pope Innocent III preached a new crusade. Thousands of French knights took the cross, eager to liberate the Holy Land. They arranged for Venice to take them by sea, the preferred route now that Italian navies dominated the Mediterranean. In return for a huge fee, Venice agreed to suspend all other operations for one year and devote its efforts solely to this crusade.

However, when the crusaders found out the plan was to conquer Egypt and trade it for Jerusalem, two-thirds of them never showed up. The one-third that did show up were now stuck with a huge bill they couldn't pay.

The doge of Venice, Enrico Dandolo, who was 80 years old and blind, but still sharp as a tack, pressured the Crusaders to storm the Christian city of Zara on the Dalmatian coast (modern Yugoslavia) as payment.

The pope was furious, but Enrico wasn't done yet.

As the crusaders were about to set out for Egypt, a dethroned Byzantine emperor arrived in their camp, offering huge sums of money and military support for the crusaders if they would first put him back on the Byzantine throne. So the crusaders now sailed for Constantinople.

When they first saw Constantinople, the crusaders were awe struck at its size and majesty. However, under Dandolo's leadership, they besieged the land walls, while the Venetian navy was able to crash through the chain guarding the harbor and attack the harbor wall, the weakest part of the city's defenses.

This was crucial in persuading the emperor in Constantinople to abandon his throne and flee for safety. The crusaders restored the other claimant to the throne, but here was one problem.

The Byzantines didn't have the money or troops they had promised Venice and the crusaders.

Therefore, a second siege ensued, during which the crusaders broke in and sacked the city.

The crusaders committed atrocities normally reserved for non-Christians. However, in the crusaders' eyes, the Byzantines were heretics and so deserved nothing better.

"I do not know how to put any order into my account, nor where to begin, continue or end the story of what these monsters committed. They broke the holy images, beloved of the faithful. They hurled the sacred relics of the martyrs into unmentionable places. They scattered the body & blood of the savior. These precursors of Anti-Christ seized the Chalices & patens, tore out their precious stones & ornaments, & drunk from them..."-- Greek historian Choniates

Choniates remarked that even the Turks would have shown more mercy.

Two and a half centuries later, they would prove him right.

The Latin Empire founded in the aftermath of the Sack of Constantinople during the Fourth Crusade was a feeble entity that fatally weakened the Byzantines, the Crusaders' main potential ally in the East while denying the Crusader states vital help from Europe.

“Jerusalem, Jerusalem”:

The Later Crusades (1228-1270)

The Children's Crusades. In 1212, two boys, one French and the other German, inspired other children to go to free the Holy Land, believing their pure hearts would open the sea before them & give them victory. The French children arrived at Marseilles. However, when the sea didn't open up for them, two merchants, Hugh the Iron & William the Pig, offered to take them to Palestine for free. Instead, the credulous children were sold into slavery in North Africa and were never heard from again.

The German children, led by a boy named Nicholas, fared a bit better. When they arrived in Rome, the Pope told them to go home. Some went on to unknown fates. Some were taken in by local families. A few made it home. Nicholas' father was blamed for this fiasco and lynched by an angry mob of parents.

The Fifth Crusade (1228-9) was led by Frederick II of Germany, a unique ruler who was more interested in Muslim culture than Christianity. Frederick was constantly at odds with the papacy, which excommunicated him for delaying his crusade for years. When he finally did go, he made friends with the Egyptian sultan who gave him Jerusalem, but without fortifications. However, the pope refused to lift the ban of excommunication because Frederick hadn't killed any Muslims to get Jerusalem.

It didn't matter though, because the demolition of Jerusalem's fortifications made it vulnerable to attack, and it fell back into Muslim hands soon after Frederick returned home.

The Sixth Crusade (1248-50) under Louis IX of France (Saint Louis) was directed against Egypt in the hope of being able to trade it for Palestine. The strategy actually worked when the French took the city of Damietta.

However, the saintly Louis refused to negotiate with the Muslims when they were ready to give in.

Then everything started going wrong. The Nile floods severely hampered any movements by the French army. Louis' army got bogged down in a siege of Mansourah, which combined with the heat and humidity brought disease.

During that siege, the crusaders charged blindly through the city's unguarded gates and were ambushed from the city's side streets and alleys. Many of the Templars who had accompanied Louis were killed here.

Finally, Louis retreated with his sick army, but was finally forced to surrender his whole army and agree to pay a huge ransom to get it released.

***The Seventh Crusade (1270)*, also led by Louis IX of France, was directed even further afield from Jerusalem, this time against Tunis in North Africa. The idea was to block Muslims from the passage between Tunis and Sicily (which was held by Louis' shrewder and more practical brother, Charles of Anjou).**

Once again, disease did its work, this time claiming Louis, who died with the words "Jerusalem, Jerusalem" on his lips.

THE RISE OF THE FRENCH FEUDAL MONARCHY (c.1100-1300)

In addition to the rise of towns and a money economy, the High Middle Ages also saw the development of strong feudal monarchies in Western Europe, especially in France and England. These feudal monarchies were a transition between the personal and decentralized feudal system of the Early Middle Ages and the more highly centralized nation states of the modern era. At the beginning of this era, most people may have believed in the concept of Universal Empire or Universal Church (as embodied in the Holy Roman Empire in Germany and Roman Catholic Church respectively). However, by the end of this era, it was becoming increasingly apparent that the future belonged to neither Church nor Empire, but to these newly emerging nation-states. Prominent among these was France. There were four main factors leading to the rise of the French feudal monarchy.

First of all, there was the ability of the Capetian dynasty to keep its hold on the throne, and that hinged on three things. First of all, the Capetians were lucky to consistently produce male heirs, which eliminated the need to look outside the Capetian family for a new king to succeed the old one. Second, the Capetians practiced primogeniture, ensuring that what little they controlled stayed together under one ruler, unlike the disastrous policy of earlier kings of dividing the kingdom. Finally, they ended elective monarchy by having their sons rule jointly with them, ensuring a smooth transition of power when the older king died. Over time, the Capetians gradually replaced the elective monarchy with the dynastic principle of son succeeding father to the throne.

The second factor, the medieval agricultural revolution, helped both the French kings and the great dukes and counts since they owned most of the land being cleared and could support the surplus population needed for towns. In contrast, lower nobles had neither the land to support towns nor the power to defend them.

However, the rise of towns ultimately helped kings against even the dukes and counts, because townsmen and kings were natural allies against the nobles. While the towns could supply kings with militia, their primary means of help was money

with which to buy mercenaries who were much more reliable than feudal armies. Bit by bit, this alliance of towns and kings helped break the power of the nobles.

The kings' legal position as supreme judge in the land was the third factor helping them. No matter how weak a king might be, his crown distinguished him as the supreme judge whom townsmen and lower nobles could appeal to over the heads of their own lords. When kings were weak, this was done on a very local level. However, it helped kings gradually establish their power over the local nobles and assert their authority on a wider level.

Finally, there was the kings' religious position, symbolized by the Church anointing them with oil to mark them as God's chosen agents on earth. Although this raised the question of who had more authority, kings or the churchmen who anointed them, it did give the king a certain amount of religious sanctity that medieval people took very seriously. In addition, the king's sanctity also symbolized his alliance with the Church, whose powers, in particular the power of excommunication, could be very useful in bringing rebellious nobles under control. It is significant that Louis VI's right hand man was a churchman, Suger, abbot of St. Denis.

Together these factors (the Capetians' firm grip on the throne, their sacrosanct nature, their position as supreme judge, and their alliances with the towns who could also supply money with which to buy mercenaries) allowed kings to gradually expand and exert their power and authority across France. That, in turn, enhanced their judicial and religious authority, bringing them into contact with more towns that could ally with the kings and provide more taxes for mercenaries, and so on.

For over a century (987-1108) the Capetians could barely hang onto their throne, but they did manage to survive. By 1100, in addition to the king's realm around Paris, known as the Ile de France, France's numerous independent feudal states were largely gathered into five greater feudal states: Flanders, Normandy, Toulouse, Aquitaine, and Burgundy. Even in his own small realm, the king's vassals defied him. At one point, the king was taken prisoner by a particularly unruly vassal and only rescued by the loyal militia of Paris. However, the succession of Louis VI in to the throne in 1108 marked the beginning of over two centuries of expansion for the French monarchy and the Capetian dynasty. During this time, seven kings reigned, three of who were especially capable. These three kings, Louis VI, Philip II, and Louis IX, would especially exploit the cycle mentioned above to lay the foundations for the modern French nation.

Louis VI (1108-1137), known as "the Fat" started the process of building up royal power. The first step, which he accomplished, was to establish the king's authority in his home territory around Paris. Confronting Louis were several rough and obstinate barons renown for their lawless ways. Louis had one valuable ally, Suger, abbot of St. Denis, who brought the power of the Church down against these nobles. In general we find the Church allied to the kings during this period, since both were concerned with ending the chronic violence and feudal warfare plaguing the land. Suger was a staunch and valuable ally throughout Louis' reign.

Louis' usual method was to call a noble to his court to account for the crimes his vassals and subjects accused him of. Often, the noble refused to come, giving Louis the legal excuse to claim the noble's lands now belonged to the king. Of course he had to enforce such a declaration and drive the noble off of the land. One potent weapon at the king's disposal was excommunication of the noble by the abbot Suger. This released the noble's vassals from any legal obligations to him and deprived him of some, if not all his support.

Louis still had to ride constantly with his troops from one end of his realm to the other, burning nobles' castles and wasting their lands in order to bring them to heel. It took him seven years to break the power of a certain Hugh de Puiset and sixteen

years to subdue another noble, Thomas de Marley. This was because Louis had little money and had to rely on feudal armies to break his vassals. Therefore, he could accomplish little in the 40 days of campaigning he got each year. Once he was gone, the noble could rebuild any burnt castles and restore much of his power.

Still, the effects of excommunication and yearly raids gradually broke the nobles' power. By the end of Louis' reign, the Ile de France was firmly in royal control, giving the king the troops and resources to expand even further. Louis' prestige was enhanced to the point that he was able to restore the infant lord of Bourbon and bishop of Clermont to their rightful places. He was even able to arrange a marriage alliance between his son and Eleanor, daughter and heiress of William X, the powerful duke of Aquitaine. Much of the subsequent history of France and England would revolve round this woman.

Louis VI finally takes his rebellious vassal, Thomas de Marle prisoner. Called a "lecherous sadistic enemy of all mankind," Marle went to war against his own father, cut the throat of an ecclesiastical kinsman who displeased him, protected brigands who had murdered the bishop of Laon, and seized Church property for himself. Even church officials gave money to Louis' campaign to destroy Marle's forts.

When Eleanor of Aquitaine married Louis VII (1137-80), she claimed she married a king only to find him a monk. Eleanor's fun loving ways certainly clashed with the pious king's personality and eventually led to getting the marriage annulled. Not only did this cost Louis the valuable lands of Aquitaine, it let Eleanor marry Henry II of England. The result of this union was what is known as the Angevin Empire, whereby the king of England controlled Aquitaine in addition to his hereditary

lands of Normandy and Anjou (hence the name Angevin). This gave Henry II control of one-third of France, much more than the king of France, his nominal overlord, ruled. However, the size of Henry's empire alarmed other French nobles and drove them to support Louis. At the time the English holdings seemed like a threat to the very existence of the French monarchy. The next French king, Philip II, would destroy this threat.

Philip II (1180-1223), called "Augustus", was certainly one of the greatest of French monarchs, being responsible for establishing the French monarchy as the recognized power throughout most of France. He was an astute and unscrupulous diplomat, though not a great general. In the early years of his reign he was lucky to maintain his own against Henry II, his main tactic being to stir Henry's rebellious sons against their father. Philip had little luck against the warrior king Richard I "the Lion-hearted" (1189-99). His luck was better against Richard's brother and successor John I (1199-1216) of Robin Hood fame.

Philip skillfully used his position as John's overlord in France to bring charges against John and summon him to court. Of course, John refused and Philip declared John's lands forfeit and now belonging to the French crown. War resulted in which a powerful coalition of England, Flanders and Germany was formed against Philip. Luckily for Philip, John moved too slowly and the French king was able to crush the Flemish and German forces at Bouvines in 1214.

This battle had far reaching consequences for France, England and Germany. In France it tripled the size of the king's realm at one stroke while driving the English out of France except for Bordeaux and Bayonne. The blow to king John's prestige was such that the next year the English barons rebelled and forced John to sign the Magna Charta, one of the cornerstones of British and American democracy. Bouvines also helped some with the disintegration of the German monarchy, as we shall see.

However, our main concern here is Philip's victory and what he did with it. Not since Charlemagne had any ruler so effectively controlled France. However, times had changed, and Philip found he had different and more effective means for ruling

France than Charlemagne had. Whereas Charlemagne had been forced to rely on giving land to uneducated nobles in return for service, Philip had money and an educated middle class at his disposal to help him rule. As a result he started putting middle class *baillis* (bailiffs) paid with money, not land, to administer his far-flung state for him. Such *baillis* were loyal to him and were kept in line by the threat of the king cutting off their salaries. Also their lower social status made them less likely to try to gain power for themselves. Philip rotated them from place to place so they would not get established in one area. Since soldiers would not follow middle class *baillis* in battle, any offices requiring military duties were filled by lower nobles called *seneschals*. Being lower nobles, they were less likely to rebel, although their power and prestige could increase after years of service with the king.

The size of the king's realm and its efficient administration provided him with money that allowed him to hire mercenaries who helped him further increase his power within his realm and in areas of France still outside it. This of course gave him more revenues that allowed him to further increase his power, and so on. Philip II made the French monarchy the most powerful and respected in Western Europe. The work of his successors mainly embellished upon what he had accomplished. Keep in mind, however, that Philip was building on the foundations laid by Louis VI. Still, it is safe to say that Philip II's reign was a major turning point in French history.

Louis VIII (1223-26) made one significant innovation: the appanage system whereby younger sons of the king were given lands (appanages) to rule in the king's name. These princes were not independent rulers in their own right, such as happened with earlier Frankish kings. But the system did have its dangers, as seen by the appanage of Burgundy, which almost established itself as an independent power in the 1400's. The appanage system shows the limits of medieval government. Since royal power and prestige still depended largely on dealing with affairs in person and the king could not be everywhere at once, members of the royal family were the next best choice for enforcing royal control. Despite its dangers, the appanage system worked fairly well.

Louis IX was renowned for his sense of justice, regularly sitting under a tree so that the humblest subjects could bring their cases to him. As a boy, he supposedly opened the prisons to release their inmates.

Louis IX (1226-70), known as Saint Louis, extended royal power even further. He asserted that lower nobles could appeal directly to the king's courts over the heads of their immediate lords. Nobles were excluded from interfering with Church elections. He also hemmed in the nobles by outlawing trial by combat and making restrictive rules that took the "fun" out of feudal warfare. Nobles could not slaughter peasants or burn their crops. They had to give enemies notice of impending attacks and had to grant truces when asked to do so. Royal officials scoured the land to enforce these rules. Louis also launched two disastrous crusades that deprived France of many of its troublesome nobles, although that was not his intention. Bit by bit, peace and order were replacing feudal anarchy in France, which by 1300 was the most powerful and respected state in Western Europe.

Among Louis' more memorable achievements was Sainte Chapelle, a church in Paris noted for some of the most beautiful stained glass windows anywhere. (Hint to tourists: Most of the windows are on the second floor.)

Knights, tournaments, and chivalry

One aspect of medieval knights that still excites people's fascination was the tournament. However, the tournament originated as something much rougher and bloodier than modern movies and novels portray it.

It started when greater centralized political control by major counts and dukes and the resulting peaceful conditions made it harder for younger nobles to raid and kill and plunder to their hearts' content. In order to give them some halfway harmless outlet for their aggressions, a lord would announce a tournament pitting any willing knights from his realm against the knights of a neighboring realm.

At first, the tournament was a free-for-all melee little short of an all-out battle, the only restrictions being that it take place within a certain area and that knights, whenever possible, take defeated foes prisoner instead of killing them. Of course, the initial shock of two lines of charging knights often killed more men than real battles did. However, this was a useful way for young landless knights to make a living, since their defeated captives had to buy back their horses and armor.

Besides the previously mentioned rules, almost anything else was fair game. Numbers on the two sides didn't have to be even. Feigned retreats to lead the enemy into an ambush were used. One side even brought infantry armed with grappling hooks to haul down opposing knights. The duke of Flanders once held a tournament where his men stood on the sidelines until the other knights were exhausted from fighting and then sent his men in to finish everyone else off.

There were limits, however. It was considered unsportsmanlike when one lord brought infantry armed with crossbows to shoot the enemy from a distance, much like if an NFL quarterback carried a pistol to bring down blitzing linebackers.

Over time, as more peaceful conditions, the Church, and the Courtly Love movement gained influence, the tournament became more “civilized”. For one thing the one-on-one joust became the main event. It started as a “pre-game” warm-up where individual knights who were so anxious for the fighting to begin would single out opponents for a duel. As time went on the joust, as this one-on-one fighting became known, supplanted the melee.

Other rules and restrictions appeared: blunted lances that shattered on impact, special jousting armor reinforced on the left side, and a point system for such things as losing a stirrup or plume.

Out of this came a group solidarity among nobles that became the basis for the code of chivalry governing the behavior of nobles toward one another, much like *Bushido*, the samurai code of behavior prevailing in Japan at the same time. Added to this were efforts by the Church to tame Europe’s tough nobles and turn them into religious saints, such as in the Arthurian legend of the quest for the Holy Grail.

Festivities after the tournament, attended by “beautiful ladies”, also encouraged nobles to develop better manners. This became another aspect of the code of chivalry, as seen in tales of knights saving damsels in distress.

This code of chivalry spread to the battlefield, making warfare seem almost like a charade, especially during the Hundred Years War. For example, an English captain offered to surrender his town if the leader of the besieging army, the famous Duke of Burgundy would agree to knight him. In another example, the English Prince Edward released the French commander, Bertrand du Guesclin, from captivity when du Guesclin proclaimed how happy he was that Edward was so scared of him that he kept him in chains.

Chivalry, however, did not extend to the common people who were mercilessly attacked and plundered. For instance, during the siege of Rouen in the Hundred Years War, the French garrison expelled the civilian population of the town to conserve food. Unfortunately, the English army besieging the town refused to let the refugees through. As a result, some 12,000 helpless civilians slowly starved to death as the two armies looked on.

Chivalry’s days were numbered though, as such weapons as the crossbow, English longbow, and gunpowder evened the playing field between nobles and commoners. As a result, the rules of chivalry were gradually thrown out, although they continued to govern the behavior of men toward women until the Women’s Liberation Movement in the 1970s created new rules. However, the rules of chivalry still hang on, especially among the older generation.

ANGLO-NORMAN ENGLAND (1066-c.1300)

[Back to flowchart](#)

As we have seen, the Anglo-Saxons, largely because of pressure from the Vikings, had built one of the strongest states in Western Europe by 1000 C.E. However, the Anglo Saxons could never quite escape the Vikings. A Danish king, Canute, took over and ruled England in the early part of the eleventh century. And in 1066, William of Normandy, a descendant of Hrolf the Walker, the Viking chief who became the first duke of Normandy in 911 C.E., landed in England to claim the English crown.

The Normans had assumed at least a veneer of Frankish culture and Christianity while their dukes had built one of the strongest and best run feudal principalities in Europe. However, their most long-lasting accomplishments took place in England.

In December 1065, the Saxon king, Edward the Confessor, whose excessive piety is said to have prevented him from producing any heirs to the throne, died. William, Duke of Normandy, had a legitimate claim to the throne as Edward's cousin, but the Saxon nobles chose Harold of Wessex instead. For William, there was only one response: take the crown by force. He gathered an army of some 5000 knights and infantry, promising his followers land in England. He also was armed with a papal blessing and banner, partly because the Norman dukes' liberally endowed the Church with lands and partly because the Pope wanted to bring the somewhat independent Saxon clergy more into line with current Catholic practices.

In 1066, Halley's comet (right of center above) passed between the earth and sun, rather than on the other side of the sun, thus making it so bright it could be seen in the daytime. Of course, such unusual celestial events were seen as foreboding some huge and/or terrible events. Scene from the Bayeux Tapestry that told the story of the Norman invasion in detail

Ironically, luck was with the Normans, since adverse winds held them up long enough for still another Viking claimant to the throne, Harold Hardraade of Norway, to land in the north. The Saxon king, Harold of Wessex, rushed north to drive out his namesake, which he did at the bloody battle of Stamford Bridge. Then he had to rush his tired Saxons southward to meet the Normans who had now landed in England.

The Battle of Hastings (10/14/1066) pitted mounted medieval knights against the Saxon infantry drawn up in a shield wall on the crest of a ridge. Frontal assaults by Norman knights, infantry, and archers could not make a dent in the shield wall. Norman trickery could. Feigning retreat, the Norman knights drew groups of Saxons out of formation, surrounded them, and wiped them out. Being weakened several times by this tactic, the Saxon army then came under a barrage of arrows and one final charge of Norman cavalry that won the day. This gave William the crown and the title "the Conqueror", which was much more appealing than his previous nickname "the Bastard". Never since has England fallen to foreign conquest.

Much more remarkable than William's victory was how he consolidated it through a combination of feudal practices from the continent and old Saxon customs. While he owed his followers land, William also wanted to keep them from getting too powerful as had happened to the French monarchy. The solution was to give the nobles lands, but scatter them over England so that they could not gather power in one area as a threat to the king. There were exceptions to this, notably on the frontiers bordering Scotland and Wales where power needed to be concentrated for defense. William also took about 20% of England's land for

himself, showing that it was still a primary source of power. He demanded a large feudal army totaling 5000 knights from the 180 barons to whom he had given land, which forced them to subinfeudate their lands to meet this quota. Thus England quickly came to resemble the feudal monarchy of France. The Normans also built some 500 castles in England between 1066 and 1100 AD, to guard against native uprisings as well as foreign invasions.

William also used several Saxon institutions to great advantage. He demanded from each freeman in England a personal oath of loyalty that took precedence over any feudal oaths vassals paid their lords, thus strengthening ties of loyalty to the king. He continued to collect the only non-feudal tax in Western Europe, based on the *Danegeld*, which the Saxons had originally paid to buy off the Vikings and later to pay for defense against them. Although he allowed the Church to set up its own independent court system in England as it had on the continent, William kept tight control of the elections of bishops, archbishops, and abbots. He saw these men as his ministers and entrusted them with much local power and responsibility. Finally, William used the Anglo Saxon officials, earls and sheriffs to look after the king's interests. Under William I and his son William II these were usually strong nobles who had the independent means to enforce their king's will, but could also be a threat. Later kings used lower nobles who, being dependent on the king for their positions, were both more loyal and less dangerous to the king.

The two centuries after William I's reign (1066-1087) saw the growth in the power and sophistication of royal government. At the same time, various Saxon democratic practices reasserted themselves and became an inherent part of the Anglo-American tradition of democracy. There was a constant struggle during this period between kings and their barons over their respective rights and obligations. In times of weak kings, the nobles won the upper hand. However, most of England's kings were strong and able to extend royal power.

Henry I (1100-35) started a more efficient treasury system, thanks to the introduction of Arabic numerals and the *exchequer*, named after the checkered table cloth they used to organize the king's money in rows. The court system also saw

advances, with the king adopting the Anglo Saxon belief that such personal crimes as murder, rape, and arson were also crimes against the king and state. Henry used this principle to send his justices throughout the land to try such cases. Henry also married a Saxon princess and, in the process, signed a charter where he promised to rule less harshly in the Norman manner and more in accordance with Saxon rights and customs. This charter would heavily influence the Magna Charta signed a century later.

After the feudal anarchy and civil wars during the reign of the weak Stephen I (1135-55), Henry II (1155-89), one of England's greatest monarchs came to the throne. As a feudal ruler, Henry still had to deal with the privileges and obligations of his noble vassals. However, as king, he claimed certain special rights and privileges to increase his power. Some of Henry's greatest accomplishments were in his legal reforms. Previously, private citizens had to bring charges against criminals, who often prevented such proceedings by intimidating their victims. Even without intimidation, few people wanted to risk bringing cases to court, because they had to pay a severe penalty (*talion*) if they lost. Henry changed that by having the state, not private individuals, bring suspects to trial. He also established grand juries whose duty was to gather evidence and submit the names of any likely suspects of crimes. Failure to do this resulted in heavy fines. As a result, more cases were brought to trial, a greater degree of law and order was established, and the king made money from the increased court revenues. The concept of state prosecution of criminals and fact-finding grand juries is still a major part of our legal system going back to Henry II. Ironically, suspects brought to trial demonstrated their guilt or innocence through ordeals, such as by water. However, even if a suspect passed the ordeal but he was still suspected of the crime, the king might exile him from England.

Henry II is also remembered for his marriage to Eleanor of Aquitaine, whose lands gave him control over one-third of France. However, the Angevin empire, as it is called, was more trouble than it was worth, since Philip II of France, technically Henry's overlord for his French lands though he was much weaker than the English king, was always trying to stir up trouble and revolts. However, Henry and his

older son Richard I, known as “the Lionhearted” (1189-99) for his exploits in the Crusades, held their own against Philip.

Unfortunately, Henry’s younger son, John I (1199-1216), was not so effective. John got into trouble on a number of accounts: losing a quarrel with the Pope, overtaxing England for his war against Philip, and then losing that war. All these problems led to a revolt of the English barons who forced John to sign the Magna Charta in 1215. Based largely on Henry I’s charter a century earlier, this was basically a feudal document, but it put forth the principles that not even the king was above the law and that no free man could be arrested without due process of law and a trial by his peers. This idea of due process of law is still a vital part of our legal system today.

The long reign of John's son Henry III (1216-1272) saw the barons under the leadership of Simon de Montfort controlling the government and usurping many privileges. However, Henry’s son, Edward I (1272-1304), was a strong king who reestablished royal authority over the nobles, conquered Scotland and Wales, developed the Welsh long-bow into the weapon that would rule the battlefields of the Hundred Years War.

Edward I is also remembered for his governmental reforms, and especially the evolution of Parliament. Originally, this was any meeting of the king and his vassals or subjects to talk (*parley*), usually over taxes. Since negotiating taxes with each town and shire was cumbersome, Edward called the Model Parliament in 1295. This body consisted of representatives from all three estates. Although later parliaments did not necessarily contain all these elements, in time it came to be the rule that all three estates should be represented.

Parliament became especially important in England for a couple reasons. First of all, England being an island enhanced its trade and the status of the middle class. As a result, the middle class merchants and lower nobility (*gentry*) were thrown together in the House of Commons. In time, their common interests led to a powerful combination capable of challenging royal power. Secondly, since England was an island, it faced few invasions, giving little need for heavy taxes to pay for expensive armies. This, in turn, left English kings

relatively weak, so that, by the 1600's, Parliament would have both the power and the constitutional right (or so it thought) to usurp much of the king's authority and lay the foundations of modern democracy.

Hastings seen through the Bayeaux Tapestry

Actually a 230-foot long embroidered cloth rather than a woven tapestry, the Bayeaux Tapestry tells the story of the Norman invasion in a strikingly dynamic visual format. Below are some selected scenes illustrating crucial stages of the battle.

Wearing only leather jerkins or quilted coats for protection, Norman bowmen advance within 100-hundred-yards from the enemy line, & let loose a barrage of shafts that clatters against the shield wall like a hailstorm. When they make not a dent in the human fortress, William orders his knights forward into the fray.

Bretons, Normans, and European mercenaries pound toward the seasoned housecarls, Harold's personal troops on the hilltop. Ranks stand so packed that the slaughtered cannot fall. Steel clashes against steel, and the awful drone of javelins fills the air.

Wielding battle-axes and hurling spears and stones, the English give measure for measure.

"They bravely withstood and successfully repulsed those. ... at close quarters," wrote William of Poitiers, and inflicted loss upon the men who were shooting missiles at them from a distance." The Saxons' long two-handed battle axes took an especially heavy toll on the Normans' horses, bringing both horse and rider down and leaving the knight in his heavy chain mail armor vulnerable to further attack as he struggled to get up.

The Bretons begin to waver. Stallions, their bloody flanks flecked with foam, stumble as their riders turn in retreat. Despite Harold's order to stand fast as a defensive bulwark, English rustics of the fyrd, or militia, filling out his ranks feel the flush of victory and break out in pursuit.

Trapped on a hillock in the valley, the over-anxious Anglo-Saxon militiamen fight to the last man against encircling invaders. Galloping past, Bishop Odo rallies the Norman cavalry with his swinging mace, a weapon he prefers so he doesn't shed blood while killing Saxons. In the melee William's horse is thrice cut from under him.

To quell rumor of his death, the duke doffs his helmet and cries, "Look at me well! I am still alive and by the grace of God I shall yet prove victor!" Eustace of Boulogne, carrying the papal banner symbolizing Rome's approval of the invasion, points out his commander.

As Saxon casualties mount, they shorten their line so the better armed huscarls and thegns can fill the front line. However this exposed the Saxons' flanks to attack. Towards the end of the day, the bone-weary, haggard Normans call upon their tired steeds for a final charge, vowing to breach the English line while archers (in the tapestry border) aim their arrows in a high arc over the wall of shields and death rains upon the Anglo-Saxons.

The shafts take their toll. The shield wall begins to crumble, exposing Harold to mortal danger. Rushing in, a mounted Norman knight hews down the doomed monarch with one mighty blow from his broadsword. Their stalwart leader dead, their army shattered, the English have little heart left for battle.

"They... began to fly as swiftly as they could," wrote William of Poitiers. Behind them, "The blood-stained battleground was covered with the flower of the youth and nobility of England." The sun set on the field - and on Anglo-Saxon England. (Scholars believe two missing panels at the end may have portrayed William on the throne of England.)

The Subjugation of England

While claiming England's crown took just one battle, reducing the countryside after Hastings took another five years for a force of some 10,000

Normans, Bretons, and French to reduce a population of 1.5 million Anglo-Saxons. And it was a brutal occupation. William replaced 13 of England's 14 Anglo-Saxon bishops with Normans who in turn replaced the older liturgy and Gregorian Chants with a newer style favored by the reforming papacy.

At the monast. of Glastonbury the new Norman abbot, wanting to oust the Saxon monks, cut their already meager rations, but they failed to give in. Finally, in a rage, the abbot called in troops who chased monks into church, broke down the doors and butchered the monks.

Likewise, Saxons were displaced of all but 8% of their land by their new Norman overlords who neither knew the language or cared about subjects who spoke it. In fact, it would take 300 years for the two tongues, Old English and Norman-French, to merge into what we know as the English language. The first major work of literature in this hybrid would be Chaucer's Canterbury Tales in the 1300s. Until then, the nobles and court would speak French while the commoners spoke the older Saxon tongue.

Not that the Saxons took all this lying down. There were revolts, sometimes supported by the Danes who mainly came to plunder and destroy and then leave the Saxon's to William's mercy.

In 1070, a leader known as Hereward the Wake led a rebellion from the fens and marshes. To bring him down, the Normans' first used a siege tower, even hiring a local witch to curse the Saxons from its top. However, when the tower caught fire she turned around to curse the Normans who had gotten her in this mess.

Nothing daunted, the Normans built a causeway across the fens and mounted an assault that finally overwhelmed Hereward's men. However, Hereward escaped & continued the struggle, earning legendary fame among the Saxons.

When the Saxons took to murdering Normans, William declared a huge fine for not turning in the murder. So the Saxons would mutilate their victims so they couldn't be identified as

Normans, causing William to declare any such victims were considered Normans till proven Saxons.

In 1085, facing the threat of another Danish attack, William took a census of all England to find out what the kingdom had in the way of men for military duty and taxable income. The resulting census document, the *Domesday Book*, is possibly the most complete census taken in Western Europe during the Middle Ages.

The Domesday census also shows the dire effects of the Norman conquest and can even help us track the path of devastation William balzed in pacifying the land, especially in the North. For example, the town of Horested's value fell from 100-50 shillings after 1066 and had only recovered to 60 shillings by 1086.

In 1087 while torching a French village during a campaign against the French king, William's horse stepped on a burning ember and threw him. After two agonizing weeks of pain from internal injuries, he died. His sons rushed off to secure their various inheritances without even burying him.

William II (1087-1100), known as Rufus for his red hair, was as nasty a ruler as his father. One day while hunting, an arrow mysteriously appeared in his back and he died.

His successor, Henry I (1100-35) spoke some English and was literate, something fairly new for kings. As Henry put it, an illiterate king is like a donkey with a crown. Although he acknowledged twenty illegitimate sons, he supported the papacy's campaign to enforce clerical celibacy, causing an embassy of 100 priests to petition him, crying about how destitute their wives and children would be if they were forced to annul their marriages.

Henry also married a Saxon princess, Edytha, which was not popular with the Norman rulers, but shows start of the blending of the two races.

Edytha, also known as Matilda, or Mold, had Henry sign a charter agreeing to give up the dictatorial powers of William I and II and guaranteeing a return to the more constitutional rule of Saxon kings and civil rights of people. Only certain taxes could be levied on the people, and some protections for commoners against the nobles was provided.

This charter became the basis for Magna Charta, with Anselm, archbishop of Canterbury, having 100 copies being made and stashed away in churches across the kingdom. Only one of these copies survived to 1215, being dug up by Stephen Lanston, archbishop of Canterbury at the time, and used as the template for what we know as Magna Charta.

Henry II and Thomas Becket

Henry II, like other monarchs of the time, had his problems with the Church over who chose church officials and whether church law or common law was supreme. His main opponent was Thomas Becket, one of Henry's close friends that the king had made archbishop of Canterbury. To Henry's surprise, Becket went through a transformation into a pious man upholding the Church's rights against the crown.

The struggle between king and archbishop split England into two camps. Supporting the king were most of the Norman nobles, while the clergy and Saxon population backed Becket as champion of their rights. One day, Henry yelled out: *"What cowards have I about me that no one will deliver me from this lowborn Priest?"* Four of his nobles taking the king at his word, went to Canterbury and murdered Becket at the altar.

Naturally, this act backfired against the king who, to satisfy the pope and public opinion, had to do penance for the murder by walking barefoot in a hair shirt & being "flogged" 5 times by Church officials & 3 times by monks. Becket was subsequently canonized as a saint, making Canterbury the most popular pilgrimage site in England.

Legal Procedures Before Henry II's Reforms

Medieval legal procedure was an accusatory form of criminal procedure, based on Roman law, where the accuser had to prove the guilt of accused or face penalty known as talion, which often equaled the penalty for the accused crime.

There was no difference between criminal and civil cases, since individuals had to bring criminals to justice. They had to convince the judge their intentions were good and that it was an honest mistake.

- Edward I declared Talion should compensate the accused for damage to him & his character
- In cases where the accused was imprisoned for the trial, the accuser was also often imprisoned
- When notifying the judge of a proposed law suit, the accuser must provide written proof. If it was insubstantial in judge's eyes, the accuser paid talion before trial
- Trying to withdraw the case led to paying talion
- Conviction required a spontaneous confession or overwhelming proof "clearer than noonday light"
- Failing these, the accused submitted to trial by ordeal, since human judges had failed. These included:
 - Ordeal by water, where water, the symbol of purity, accepted the innocent and rejected the guilty. Presumably the innocent were fished out before they drowned.
 - Holding a red hot iron or plunging his arm into boiling water, then checking how well the wound healed
 - Ordeal by barley bread: a piece of bread marked w/cross was suspended in church by a hook in the presence of the accused; if guilty the bread would revolve. (Safety tip: if accused, try not to schedule the trial on a

windy day in a drafty church.)

- Ordeal by unleavened barley bread & cheese (which must be made in May from a ewe's milk). These are given to the one accused of theft. If after swallowing, any was left on the corner of his mouth, he was guilty.

Nobles generally relied on ordeal by combat.

English sayings and their origins

"Don't throw the baby out with the bath water"

Baths were rare, but, when given, a big tub was filled with hot water. Dad went 1st with the clean water. Next came adult sons, then the women, children, and finally babies. By then the water so dirty, people would warn not to throw the baby out with the bath water. Yearly baths were typically taken in May, leading to most marriages taking place in June while the couple were still smelling pretty. Just in case, the bride carried a bouquet of flowers to hide body odor.

"It's raining cats & dogs"

Since thatched roofs were the only warm place for animals, mice, rats, cats, and even dogs lived there. When it rained, the thatch became slippery, causing any inhabitants to fall out, thus raining cats and dogs.

Four-post canopy beds evolved since there was nothing to stop bugs, etc. from falling on the bed.

"Dirt poor" & threshold

Only the rich had floors of something other than dirt, giving rise to the saying "dirt poor."

The rich had slate floors, which were slippery when wet. So they spread thresh to help keep footing. As they kept adding more thresh it would all slip outside when the door opened. Therefore, a piece of wood was placed at the entryway, becoming known as a "threshold".

"Bring home the bacon" & "chew the fat"

Pork was a rare and special treat for most people, so that when a man would bring out some bacon and hang it to show off to company, it was a sign of wealth and that a man "could really bring home bacon." They would then cut off a little to share with guests while "chewing the fat."

"Trenchmouth"

Most people only had trenchers (piece of wood w/middle scooped out) from which to eat. Since they were never washed, worms often got into the wood. After eating off these wormy trenchers, they would get "trench mouth."

The rich had pewter plates, causing some lead to leach onto their food, especially tomatoes. As a result, they stopped eating tomatoes for 400 years.

"Upper crust"

Bread was divided according to status, where workers got the burnt bottom of the loaf, family members got the middle, and guests got the top, or the "upper crust".

"WAKES",

Since ale & whiskey were drunk from lead cups, drinkers were sometimes knocked out for a couple days and often taken for dead. They would be prepared for burial and laid out on the kitchen table for a couple of days while family gathered, ate, drank and waited to see if they'd wake up. Thus the term "wake".

Graveyard shifts, saved by the bell, & dead ringers

When England started running out of places to bury people, they'd dig up coffins, take bones to a house, and re-use the grave. Reopening these coffins they found one in twenty-five had scratch marks on the inside, leading to the realization that they had been burying people alive. As a result, they would tie a string on the corpse's wrist and lead it from the coffin to a bell. Someone had to sit in the graveyard all night to listen for the bell during this so-called "graveyard shift." They'd know if someone was "saved by the bell" or a "dead ringer".

THE HOLY ROMAN EMPIRE OF GERMANY (919-c.1300).

Introduction. The history of the Holy Roman Empire, as Germany was then known, differed quite markedly from France and England. Whereas those two countries were well on their way to developing national monarchies by 1300, Germany was disintegrating into feudal anarchy. This was largely the result of Germany being tied to the ancient and somewhat outdated concept of a universal Roman Empire that claimed dominion over all of Europe. This put it into conflict with the Catholic Church, which had its own claims to universal dominion. The ensuing centuries long struggle between popes and emperors would exhaust the empire, destroy most of the emperors' authority in Germany, and leave it in the power of independent princes and church prelates. Also, the quickly emerging nation states had little room for the idea of a universal empire interfering in their affairs. The concept of such an empire may have had some appeal in the time of Charlemagne. Five hundred years later the luster of such claims was tarnished and starting to rust.

The Saxon Dynasty. The breakup of the Frankish Empire in the ninth century created two main states: West Frankland, which would become France, and East Frankland, which would become Germany. The death of Louis the Child in 911 put an end to the German branch of the Carolingian dynasty, forcing the German nobles to choose a new ruler. Largely because they recognized the need for a strong monarchy to protect them against the nomadic Magyars to the East, the nobles chose the rulers of Saxony as their king. In the following century, the Saxon dynasty (919-1024) established one of the strongest of the early medieval monarchies. The Saxons based their power, as most monarchs then did, on the twin pillars of holding land and an alliance with the Church.

In addition, the Saxon rulers did two other things to strengthen their alliance with the Church. For one thing, they supported the spread of the Cluniac reforms into Germany, largely as a means to weakening the power of local nobles. Secondly, in 961 the pope and Italian bishops called in the Saxon ruler, Otto I, to defend them against their enemies. In return for this favor, the pope crowned Otto Roman Emperor. From this time until 1806, the

imperial dignity would belong to the rulers of Germany, known afterwards as the Holy Roman Empire.

The Salian Dynasty (1024-1106), which succeeded the Saxons, also depended on controlling Church officials and large amounts of land to maintain and build its authority. In addition, the rising power of the nobles made it even more mandatory that they form a more efficient administration. In the absence of towns at this early date, the Salians used a peculiar institution known as *ministeriales*. These were originally non-free peasants whom the Church would use for knight service to the emperor. The bishops and abbots would give the ministeriales use, but not possession of land to pay for these services. The Salian emperors used ministeriales for various military and civil services, since their low social status kept them dependent on the emperor. They also drew silver from the mines in the Hartz Mountains, which gave them still more power.

Their power and policies made the Salians unpopular in Germany, especially with the nobles. However, by 1075, the emperor Henry IV seemed well on his way to building the strongest monarchy in Western Europe. He had extensive lands, a permanent capital at Goslar, money revenues, and a body of servants loyal to the king. Unfortunately, as we have seen, the emperors' support of the Church reforms had also raised the power and status of the popes who then challenged the emperors' control of Church elections in Investiture Struggle (1075-1122). When pope Gregory VII excommunicated Henry, the German nobles seized the opportunity to rebel against their emperor and elect a new ruler. Rebellions, civil war, and anarchy tore through Germany and Italy. Pope Gregory VII died in exile, but his successors

continued the struggle. When Henry IV died, his successor, Henry V, finally managed to reach a compromise settlement, but the damage was already done.

The anarchy and wars of the past half a century had allowed the German nobles to assert their independence. Great nobles became virtually independent princes, while the lower nobles became their vassals. Bishops and abbots also granted fiefs in return for military service. The free peasants virtually disappeared. Even the ministeriales were forced to break their bonds of service to the empire and become other nobles' vassals as the empire started to fragment.

What ensued was a vicious cycle whereby German emperors, seeing Germany as increasingly hopeless and themselves as Roman emperors, would neglect Germany and concentrate on building their power in Italy. As a result, Germany would disintegrate into worse anarchy. This would encourage the emperors to concentrate further on Italy while ignoring Germany, and so on.

This process especially accelerated under the Hohenstauffen dynasty, starting with its first emperor, Frederick I Barbarossa (1152-1190). Frederick I first tried to reassert imperial power in the rich cities of Lombardy in north Italy. After some initial successes, he was defeated by the combined forces of the Lombard League in 1176. Although they acknowledged him as their emperor and paid some money, they remained virtually independent. Frederick did manage to seal a marriage alliance of his son to a Norman princess of Southern Italy and Sicily. Frederick also had some success in controlling the cities in Central Italy. This had the effect of alarming the popes who became the avowed enemies of the Hohenstauffen emperors surrounding them.

Frederick I is said not to be dead, but a sleeping hero in a cave in Kyffhäuser mountain in Thuringia, Germany where his red beard has grown through his table. When the ravens that fly around that mountain stop doing so, he will awaken and restore German power and glory.

Frederick Barbarossa died while on Crusade in 1190. His son and successor Henry VI, being married to Constance of Sicily was even more involved in Italian politics. For one thing he had to spend several years putting down a rebellion of Norman nobles who did not want a German ruler. Although Sicily brought the empire a very well organized and wealthy state, it also kept the emperors out of Germany even more, allowing it to disintegrate further. The acquisition of Sicily also further alienated the popes who were now surrounded with an even tighter noose.

The last great "German" emperor, Frederick II (1196-1250) came to the throne as a baby. After a stormy childhood, during which pope Innocent III was his guardian against more threatening German nobles, he came to the throne in high own right. Frederick was one of the most fascinating medieval characters, keeping Muslim advisors, a harem, and a menagerie of exotic animals. His irreligious ways shocked contemporaries. Even his crusade where he gained Jerusalem through negotiation rather than fighting with the Muslims did not seem quite Christian.

Frederick grew up in Sicily and considered Germany too cold and bleak for a home, spending only two years of his reign there. His policy there was to keep it quiet so he could concentrate on building his power in Italy and fighting the popes. As a result, he was willing to grant further privileges to the German nobles in order to pacify them. The last vestiges of imperial control fell into the hands of nobles who were now granted full powers of government in their individual lands. The popes added to the confusion as they stirred up rebellions against Frederick in both Italy and Germany. Although Frederick maintained his power in Italy, he never succeeded in breaking the popes' power. Even after his death in 1250, the emperors' fight with the popes continued.

The popes finally emerged victorious in their struggle with the German emperors. They broke the ring of enemies surrounding them by inciting rebellions in the cities to the north and bringing in the French royal prince, Charles of Anjou, to overthrow Frederick's son in Sicily and Southern Italy. The pope even forced loans out of the Italian bankers by threatening to ruin them with a decree absolving all debtors from their obligations to the

bakers. The means that the popes used to defeat the emperors also served to tarnish their own reputations and that of the Church.

In 1350, the German monarchy became purely elective, further weakening the power of the emperors. By 1500 Germany would be a patchwork of some 300 independent states nominally united under the empire (below). For centuries, Germany, too weak and divided to defend itself, would be a constant battleground for other powers' wars. Even after its unification in 1871, the memory of these humiliations would largely determine Germany's foreign policy and be an underlying cause of the two world wars in this century.

The Kingdom of the Two Sicilies (1016-1282)

In 1016- Norman pilgrims returning from Palestine stopped at the shrine of the Archangel Michael in Southern Sicily, where they were approached by a local Lombard, Melo who enticed them with stories of vast wealth to be made from being mercenaries. As word got out back to Normandy, thousands of land hungry younger sons made their way to Italy, first as mercenaries, and then as conquerors of their own principalities. The most famous of these was Robert Guiscard who carved out a state encompassing all Southern Italy at the expense of the Byzantines and local Lombards.

By 1100, Guiscard's nephew, Roger, had conquered Sicily, where he left Muslim governors & laws in place, making him fairly popular. In 1130, Roger II was crowned King of the Two Sicilies, which was one of the best administered states in Europe at that time.

In 1186, Frederick Barbarossa's son, Henry, married Constance of Sicily. When her nephew, Roger II died four years later without a

successor, Constance became queen, making her husband, now Henry VI of Germany its king. Henry, also known as The Cruel, was a ruthless ruler, and thus very unpopular. When his wife, Constance, had a baby at age 40, rumors circulated that it was the result of demonic possession. Thus, when Henry died, leaving Germany and the Two Sicilies to his infant son, Frederick II, Germany degenerated into civil war making for a somewhat turbulent childhood for the young king.

While, on a map the Hohenstauffen dynasty's empire looks impressive, its apparent power made it a number of enemies, namely the popes, the Italian city-states in the North, and the German nobles fighting for their own independence. Also, it was too spread out to administer effectively without a trained and loyal bureaucracy

Frederick II meets with the Egyptian sultan al Kamil Muhammad al Malik during the Fifth Crusade. The two men became friends and the sultan turned an unfortified Jerusalem over to Frederick. The pope, who had excommunicated Frederick for delaying his crusade, refused to lift the ban because Frederick hadn't fought to recover the Holy City.

Castel del Monte, built by Frederick II in Southern Italy. The Hohenstauffens, in particular Frederick II, used a variety of troops for their armies. Frederick's Muslim guardsmen were especially useful against the Papacy since being excommunicated had no effect on them.

After Frederick II's death, his illegitimate son Manfred took the throne of the Two Sicilies. However, the Pope, still fearing the Hohenstauffens, called in Louis IX of France's

brother, Charles of Anjou, to oust Manfred from power. Despite the power of Manfred's German heavy cavalry, Charles beat Manfred and took the Two Sicilies as his prize.

In 1270, having taken Sicily, Charles talked his saintly brother, Louis IX of France (AKA St. Louis) to divert his crusade to Tunis in N. Africa. While this wouldn't get Louis very close to Jerusalem, it would help cut off Muslim trade between the Eastern and Western Mediterranean.

Unfortunately, fever beset the crusader camp during the long hot siege and Louis died, supposedly with the words "Jerusalem, Jerusalem" on his lips.

In 1282, using as their signal the Church bells' announcement of the evening (vespers) prayers, the Sicilians rebelled against Charles' stern and unpopular rule. This revolt, known as the Sicilian Vespers, pulled in the rulers of the Spanish kingdom of Aragon and ended up dividing these southern lands between the French Angevins in Naples and the Aragonese in Sicily.

WAR, PLAGUE, HERESY, DEPRESSION SCHISM AND REVOLT THE BLACK DEATH AND ITS IMPACT (1347-c.1450)

*"God is deaf now-a-days and deigneth not hear us,
And prayers have no power the Plague to stay."--
Piers Plowman*

Introduction. In the 1300s, Europe entered a period of turmoil that shook medieval civilization to its foundations and paved the way for such aspects of the modern world as nation states, capitalism, and the Protestant Reformation. Such periods of transition are rarely easy to endure, and this was no exception. It was a period which saw recurring famines, outbreaks of plague, peasant and worker revolts, the rise of religious heresies, challenges to the Church's authority, and long drawn out wars, in particular the Hundred Years War between France and England. Ironically, the problems were largely the result of better farming methods.

Signs of growing Stress. The High Middle Ages had been a time of growth and prosperity. New agricultural techniques had caused a dramatic rise in population, which in turn led to rising demands for food and fuel. This generated inflation and a strain on the environment, which led people to clear more new lands for cultivation. That, in turn, triggered more population growth, and so on

Aggravating these problems was a change of climate. Apparently, the climate in the High Middle Ages was good, thus making possible that period's prosperity. However, in the 1300's the climate turned colder and wetter than usual, resulting in floods and early frosts. Sources spoke of great famines in 1316 and 1317 and of reports that the Baltic Sea froze over in 1303 and 1316. The resulting malnutrition of the early 1300s made people born during that time especially susceptible to disease, since our immunological systems develop during childhood. This in turn set up the worst of the Middle Ages: the Black Death.

Origins of the Plague. The Black Death, also known as Bubonic plague, appears to have arisen in Central Asia in the early 1300's. The most likely scenario for its spread points to Mongol rulers in Asia who had settled down from their rampages to establish stable caravan routes from China to the

Black Sea where Italian merchants would trade for the silks and spices so highly valued in Europe. Ironically, these trade routes were also the invasion routes of a very different sort. Apparently, the Asian black rats, which carry the fleas that carry the plague, burrowed into the caravan's grain sacks and hitched a free ride across Asia. Rumors had already filtered westward of a terrible plague that depopulated whole regions of China and India. Rumor became reality for Europe in 1347 when a Genoese ship pulled into the Sicilian port of Messina with half its crew dead or dying from plague. The Black Death had arrived.

Germ Warfare. The Plague reached a Mongol army besieging the Genoese city of Caffa on the Black Sea. According to one version, the Mongols decided to wage a primitive form of germ warfare by catapulting plague victims over Caffa's walls. When Plague broke out in the city, Genoese merchants there cleared out for home, spreading the pestilence at every port of call. By the time they reached Messina in Sicily, most of the crew were dead, sparking a panic among the townspeople, who fled the city. Unfortunately, they took the Plague with them.

The Plague quickly spread death and terror across Europe, sweeping through Italy in 1347, France in 1348, and the Low Countries, England, and Scandinavia in 1349. Its pattern was to flare up in the summer and taper off in the winter, only to flare up again and sweep onwards the next summer. By 1350, it had pretty well passed on, leaving in its wake a population decimated by its effects.

Cities, with their crowded unsanitary conditions, generally suffered worse than the countryside. Although contemporary accounts generally exaggerated the toll, it was certainly was staggering. Supposedly 800 people died in Paris each day, 500 a day in Pisa, and up to 600 a day in Vienna. Some cities lost anywhere from 50-70% of their populations. Monasteries, also being crowded, suffered similar death rates. In the countryside where people were more spread out, maybe 20-30% of the population perished.

All across Europe black flags flew over towns to warn travelers that the plague was there. Church

bells rang constantly to announce the deaths of citizens until town councils voted to silence their demoralizing clangor. The Hundred Years War was interrupted by the plague, and construction on the cathedral in Siena, Italy stopped and never resumed, a grim memorial to the plague's power.

People, having no idea then of the existence of microbes, were completely ignorant of the plague's cause. Some, seeing a correlation between fleas and plague, killed dogs and cats, just giving the black rats more freedom to spread the disease. Most explanations of the Black Death concerned divine retribution. This gave rise to the flagellants, people who would march from town to town whipping themselves to atone for society's sins. However, as they spread penitence, they also spread the plague. Therefore, the authorities outlawed them, as much for the social unrest they seemed to stir up as for the disease they were spreading. The most effective way of avoiding the plague was to avoid people who might carry it, causing those rich enough to flee the towns during the plague's height in the summer months. In fact, a virtual panic seized people as husbands abandoned wives, parents abandoned their children, and even priests and doctors refused to see their patients. It seemed as if the whole fabric of society was coming unraveled.

In the absence of any effective remedies, people looked for scapegoats. Many blamed the Jews whose religion dictated a bit cleaner lifestyle, which in turn meant less incidence of rats, fleas, and plague. In some peoples' minds, however, the Jews had poisoned the wells or made a pact with the devil to cause the Black Death. The resulting disturbances resembled those accompanying the First Crusade, with Jews being massacred or burned in their synagogues. Germany and the Low Countries saw especially bad outbreaks of such violence, and, by 1350, few Jews remained in those areas.

The plague hit Europe six more times by 1450, each time with less severity than before, since more survivors were immune to it. And those without resistance were weeded out by natural selection. Still, some 30-40% of Europe's population was lost. Census figures in England fell from 3.7 million in 1348 to 2.1 million by 1430. Even then, Europe was not free from the

Black Death's ravages, suffering recurrent outbreaks until the early 1700's. Why it receded is also a matter of controversy, with such theories as the European brown rat driving out the Asian black rat, tile roofs replacing thatched ones where rats often lived, and the more deadly plague microbe, which more readily killed off its host and left itself no place to go, being replaced by a less deadly version.

The results of the Black Death. Along with an obsession with death that worked its way into European culture for generations to come, one can see the long term effects of the Black Death following three lines of development: a higher standard of living for those who survived, problems for nobles and clergy who were land owners, and revolts by peasants and urban workers. First of all, the Black Death had raised the standard of living of many survivors who inherited estates from the plague's victims. One sign of this was that peasant families, who, before the plague, were so poor that they sat at the dinner table on a common bench and ate from a common plate, now had individual stools and plates. This higher standard of living would lead to a more even wealth distribution and the recovery of the economy after 1450.

Popular uprisings. Peasant and urban worker revolts were a sign of the times in the 1300's and 1400's for two main reasons. First of all the plague created a labor shortage, especially in the cities where up to 70% of the inhabitants had died. As a result, workers and peasants demanded higher wages for their labor, something nobles and guild masters strongly opposed. A second problem was that the Black Death had severely depleted the tax base of the medieval state. This caused kings to raise taxes drastically to meet expenses coming from the chronic warfare of the age, in particular the Hundred Years War raging between France and England. Frustration from these thwarted demands and the heavier tax burden triggered a series of urban and peasant revolts across Europe.

Typically, war, plague, high taxes, or a combination of these would spark a sudden uprising. At first it would take the authorities by surprise, and they would either be killed or flee to the safety of the local towns or castles. In the case

of peasant revolts, the unexpected success of an uprising would encourage other peasants to join and vent their frustrations on their own lords with incredible ferocity and cruelty. The rebellion would sweep through the countryside like wildfire, destroying any opposition in its path. However, the sudden nature of such outbursts also carried the seeds of their destruction, because they had very little, if any, organization or planning. Eventually, the authorities would gather their forces and crush the rebellion, since the rebels were poorly armed and trained compared to the professional warriors facing them. The aftermath would often see massacres and executions as retribution against the rebels and to discourage any further uprisings.

In the cities, workers tried to form their own protective organizations to win higher wages and better working conditions. This alarmed the guilds, which outlawed such organizations. That in turn enraged the workers who resorted to violence. The first such revolts occurred even before the Black Death hit Europe. The plague and its results merely intensified an already existing crisis.

The most serious of these, that of poor laborers known as the *Ciampi*, took place in Florence (1378) and followed a course similar to other popular revolts of the time: initial success (which in this case lasted four years), eventual victory for the authorities, and severe reprisals which only added to existing bitterness. The savagery of such revolts and the atmosphere of fear and hatred they created led the ruling classes in the cities to support princes and tyrants who could establish law and order. In Flanders, the dukes of Burgundy also established law and order under their strong autocratic rule. The greater security plus the collection of power and wealth in the hands of these rulers would be important factors supporting the cultural flowering of the Renaissance

Two revolts typified peasant uprisings, one in France and one in England. The *Jacquerie*, named after the popular name for French peasants, broke out in 1358, ten years after the Black and in the midst of the Hundred Years War with its destruction, high taxes, and forced labor to repair fortifications. On May 28, about 100 peasants in the village of St. Leu assaulted the nearest manor

house and massacred the lord and his family. From there, the revolt spread quickly across the countryside with the usual atrocities and a reported 160 castles burned. Many towns, either out of sympathy or fear of the peasants, opened their gates to them.

The turning point came when some nobles returning from crusade in Eastern Europe came across and defeated some peasants at the town of Meaux. This encouraged them to organize and gather their forces against the main peasant force. The nobles then lured the peasant leader, Guillaume Cale, into a parley and murdered him. Deprived of their leader, the peasants were easy prey in the battle that followed. Hundreds were burned in a local monastery, and thousands more were hanged in their doorways as a warning against future revolts. Less than a month after the start of the revolt, it was over, although the fear and bitterness it bred lived on.

The Wat Tyler rebellion broke out in England in 1381. The immediate causes were much the same as those of the *Jacquerie*: high war taxes, a recent outbreak of plague, and a resulting agricultural crisis. The course of events was also similar. The rebels advanced all the way to London, looting and pillaging as they came. They even managed to seize and murder several of the king's officials. However, a daring ride in front of the rebels by the boy king, Richard II, who offered them concessions and supposedly his leadership in the revolt, settled them down. A parley was then arranged with the peasants' leader, Wat Tyler, which ended in his murder. This demoralized the peasants and allowed the nobles to defeat them and restore order in England much as the French nobles had in France. However, despite their ultimate defeats, the popular revolts of the day had two important results. First, they damaged the nobles' military reputations and power and paved the way for the emergence of kings and the modern nation state. Secondly, workers' and peasants' wages did rise, also leading to a more even distribution of wealth.

Decline of the Church and nobles. The Black Death also created problems for the nobles and clergy in two main ways. First, the huge population loss in the cities' caused a virtual collapse of the urban grain markets, a major

source of income for noble and church landlords with surplus grain to sell. This especially hurt the nobles and clergy, whose incomes were still based on land and who relied on selling surplus grain in the towns for badly needed cash. There were two main strategies for making up for this lost income.

Both nobles and clergy resorted to selling freedom to their serfs. This raised some quick cash, but it also deprived them of future revenues, which contributed to their decline and the corresponding rise of kings and nation states. At the same time, the serfs were now transformed into a free peasantry with more incentive to work harder since they were working more for themselves. This also helped lead to a more even distribution of wealth which contributed to a revival of agriculture, towns, and trade, especially after 1450 when the climate seems to have improved. But with the guilds and nobles weakened by the turmoil of the last 150 years, a new broader consumer market evolved, but one where the average person had less money to spend than the average noble beforehand would have had. Since these people could not afford the guilds' expensive goods and the guilds refused to adapt to this market, rich merchants established cottage industries and sold their goods outside of the guilds' jurisdiction. The profits they made and the absence of the guilds' restrictive regulations helped these merchants establish a new economic system, capitalism, which would replace the guild system and lead the way into the modern world.

The Church had several other fund raising options in addition to selling serfs their freedom: selling church offices (simony), letting one man buy several offices at the same time, charging fees for all sorts of church services, and selling indulgences to buy time out of Purgatory after one died. These practices plus the Church's inability to cope with the crisis of the Black Death led to growing public discontent. As a result, the Church would experience serious challenges to its authority in the Later Middle Ages.

The Nature of the Disease

Rats play “Ring around the Rosie”, also a nursery rhyme about the Black Death. The rosie represented the rash victims of the plague got. The ashes referred to burning the bedding and clothes of deceased victims.

Yersinia Pestis is the bacillus that spreads plague. However, the bacillus needs a host to spread Bubonic Plague. That host was the common household flea. . In order to reach a new host, fleas can jump 4” vertically and 6” horizontally, which is 150 times their size. The flea itself needs a host on whose blood it can live. The bacillus multiplies and clogs up the flea’s stomach, forcing it to bite its host to regurgitate the blood, thus infecting its host. When its host dies, the flea must seek a new host. Its favorite host was the Asian black rat.

The Asian black rat can survive a 50’ fall and scale brick walls. It has a vertical leap of 2 feet, a horizontal leap of 4 feet, and can squeeze through a hole the size of a quarter. Unless it constantly gnaws to file down its teeth, which grow 4-5”/ per year, they will grow up into its brain and kill it. These creatures can even survive by eating excrement.

However, when the plague kills the rats, the fleas need a new host.

Dogs and cats will do just fine. So will humans. In fact, fleas were so common in medieval households that their presence was seen as little more than a nuisance, as a number of contemporary paintings of women picking fleas

off their bodies showed. (Women were typically the subject, since they were mostly at home where the fleas proliferated.) That was part of the problem: fleas were barely noticed.

Symptoms, while varying from person, followed this basic pattern:

Day 1: The 1st symptoms consisted of headaches & weakness, followed by aches & chills in the upper groin.

Day 2: A white coating would appear on the tongue, accompanied by rapid pulse, slurred speech, confusion, fatigue, apathy, and staggering.

Day 3: Lymph nodes near the flea bite would swell to the size of an egg or apple, especially in the armpits and groin. Thus the term *bubonic*, from the Greek *boubon* for groin. As one victim put it: "*...Woe is me of the shilling [i.e., buboe] of the armpit! It is seething, terrible... a head that gives pain and causes a loud cry...a painful angry knob....Great is its seething like a burning cinder...a grievous thing of ashy color.*" — Unknown

Other symptoms included a fluttering heart as it tried to pump blood through suffocating tissue, and subcutaneous hemorrhaging which showed up as bluish black splotches under skin, giving rise to the other common term Black Death

Day 4 saw wild anxiety & terror in the victim as well as intense pain & a bizarre neurological disorder commonly called the Dance of Death from the involuntary jerking around.

Varieties. There were three basic varieties of the plague, largely defined by how the victim was infected.

The Bubonic variety, coming from flea bites, killed 70-80% of its victims within five days .

The Pneumonic variety, transmitted by coughing & sneezing, which were also symptoms of the disease, was more contagious, typically killing an estimated 90% of those infected within 3 days.

The Septicemic variety directly entered the bloodstream, leading to death much sooner, often without symptoms, and having a lethality of nearly 100%. Some victims would go to bed apparently healthy and never wake up, which was probably the best way to go, all things considered.

Personal Accounts of the Black Death

"Neither physicians nor medicines were effective. Whether because these illnesses were previously unknown or because physicians had not previously studied them, there seemed to be no cure. There was such a fear that no one seemed to know what to do. When it took hold in a house it often happened that no one remained who had not died. And it was not just that men and women died, but even sentient animals died. Dogs, cats, chickens, oxen, donkeys sheep showed the same symptoms and died of the same disease. And almost none, or very few, who showed these symptoms, were cured. The symptoms were the following: a bubo in the groin, where the thigh meets the trunk; or a small swelling under the armpit; sudden fever; spitting blood and saliva (and no one who spit blood survived it). It was such a frightful thing that when it got into a house, as was said, no one remained. Frightened people abandoned the house and fled to another." --Marchione di Coppo Stefani

"How many valiant men, how many fair ladies, breakfast with their kinfolk and the same night supped with their ancestors in the next world! The condition of the people was pitiable to behold. They sickened by the thousands daily, and died unattended and without help. Many died in the open street, others dying in their houses, made it known by the stench of their rotting bodies. Consecrated churchyards did not suffice for the burial of the vast multitude of bodies, which were heaped by the hundreds in vast trenches, like goods in a ship's hold and covered with a little earth." -Giovanni Boccaccio

"Father abandoned child, wife husband, one brother another, for this plague seemed to strike through the breath & sight. And so they died. And no one could be found to bury the dead for money or friendship... And I, Agnolo di Tura, called the Fat, buried my five children with my own hands, and so did many others likewise."— Agnola di Tura

"One man shunned another...kinsfolk held aloof, brother was forsaken by brother, oftentimes husband by wife; what is more and scarcely to be believed, fathers and mothers were found to abandon their own children to their fate, untended unvisited, as if they had been strangers."--Unknown

"Realizing what a deadly disaster had come to them the people quickly drove the Italians from their city. However, the disease remained, and soon death was everywhere. Fathers abandoned their sick sons. Lawyers refused to come and make out wills for the dying. Friars and nuns were left to care for the sick, and monasteries and convents were soon deserted, as they were stricken, too. Bodies were left in empty houses, and there was no one to give them a Christian burial."--Unknown

"Bring out your dead": Dealing with Plague

A doctor who treated victims of the Black Death. The beak, filled with perfumes & other substances to ward off the plague, supposedly would filter out the bad fumes. The lenses would likewise protect the eyes from infection through transference by sight.

Burial. In many cases, there were so many dead and so few living that mass burial pits had to be used. Finding people to carry out this grim task wasn't so easy. In Florence, a religious order known as the Campagna della Misericordia collected bodies left on doorsteps until the last of them died. Since such graves were usually quite shallow, dogs and wolves would sometimes come and dig up the bodies.

Explanations for the Black Death were plentiful and imaginative:

- Earthquakes, which led to crevices through which toxic fumes escaped into the atmosphere.
- A triple conjunction of Saturn, Jupiter, & Mars that exerted unusually intense influence on earth
- Transference by sight when someone with the Plague looked at you
- Raining frogs, toads and lizards
- Lust with old women
- Baths which open pores through which Plague would get in
- Bad air, which made exercise especially risky, since it led to heavy breathing and then Plague.

The Black Death was particularly hard on European Jews. Because Judaism prescribed a very clean household, rats found little there to eat and moved on down to the messier Christian households where they shared the fleas in exchange for a few choice crumbs.

Christians, seeing the Jews suffered less from the Plague than they did, assumed they had done something like poison their wells or made a pact with the devil.

Already driven to hysteria by this mysterious disease, mobs in many cities, especially in Germany, massacred entire Jewish communities.

- In Basle several hundred were burned in a house built for the occasion.
- In Strasbourg 2000 were burned at the stake.
- In Worms 400 Jews burned themselves to death rather than be taken alive.
- Frankfurt-am-Main witnessed the same spectacle.
- Jews defending themselves in Mainz killed 200 Christians, leading to all 6000 being killed
- Similar incidents took place in Konigsburg, Freiburg, Augsburg, Nuremberg, Munich, , & Regensburg.

By 1350, few Jews remained in Germany or the Low Countries, many having fled to Eastern Europe.

Avoidance and cures. One of the best cures available was lancing or draining pus from the buboes, but common wisdom, often an oxymoron, thought that would make things worse, so the pus remained inside the victim to do its work. Another measure was to quarantine entire families in their houses when a member got plague. This may have protected people outside of the family, but it generally condemned to death everyone trapped inside. This seems to have worked in Milan, where it was strictly observed and few people died.

Then there were the silly cures:

- Sleeping on your right side, then your left.
- Breathing in urine fumes or bathing in urine, which probably would keep people with plague, (and everyone else for that matter) at a safe distance away from you.

- Drinking pus from the buboes
- Writing “Abracadabra” in this magical manner was another surefire cure

Another practice was for groups of penitents to travel around to atone for society’s sins and avert the plague. Such processions often included flagellants who whipped themselves to purge their sins. Unfortunately, by going from town to town, they also spread the plague, until the Church tried to ban them.

Popular Uprisings in the Late Middle Ages

Flemish town militia defeat French knights at Courtrai in 1304

Even before the Black Death wreaked its havoc, there were signs that the old medieval order was coming apart. Among these were popular uprisings that challenged the Old Order.

The Sicilian Vespers (1282) was the first major example of such an upheaval, being directed against the Angevin dynasty, which conquered

and misruled Sicily after the death of the emperor, Frederick II. This revolt escalated into a full-blown war between the Angevins and Aragon, with the Aragonese eventually taking Sicily.

The Matins of Bruges and battle of Courtrai. In 1297, Philip IV of France added Flanders (modern Belgium) to the crown lands, taking the rightful Count of Flanders, Guy of Dampierre, hostage, an act that angered many Flemish townsmen.

Possibly in reaction to this, the English king Edward I began to sell wool directly to customers, bypassing the rich burghers of Bruges who had the exclusive right to import wool as middlemen from England. When the burghers appealed to the French king, to restore their monopoly, Philip installed a garrison in the city, in the process driving a number of people from their homes in order to quarter his troops.

On the night of May 18, 1302 townsmen, led by Pieter de Coninck and Jan Breydel, massacred the garrison and any other French they could find, some 2,000 people. In order to identify the French, they were ordered to say "*schild en vriend*" (shield and friend), which was Bruges' shibboleth (a phrase whose pronunciation identifies its speaker as being a member or not a member of a particular group). Those unable to pronounce it correctly were killed.

Philip sent an army of about 8,000 men, including 2,500 knights and squires, to crush the insurrection. They were met by a force of 9,000 town militia from Bruges, Ghent, and Ypres. These were almost exclusively infantry armed with long spears and maces. While mounted nobles had disdain for infantry, counting one knight as worth ten of the enemy, these were well trained militia unlikely to break and run at the first sight of enemy cavalry thundering towards them.

The two armies met on the field of Courtrai, which was crisscrossed by canals and streams, making a cavalry charge difficult and even hazardous. The French first sent in servants to

bridge the canals with boards and then their infantry to soften up the Flemish. However, when they saw their infantry winning, they charged in to get all the glory, getting tangled with their own men and bogged down in the canals and streams, where the Flemish militia speared them like fish.

The Battle of Courtrai was also called the Battle of the Golden Spurs because of all the golden spurs the victorious Flemish townsmen supposedly took from the bodies of French knights and dedicated to the Virgin Mary.

The Ciompi rebellion (1378-82) in Florence was named after the wool carders, a low class of workers unaffiliated with any guild, although other workers, such as vegetable sellers and pottery vendors, and minor guilds were involved as well. They had a long list of grievances against the rulers of the textile guild, which gives us a good idea of urban working conditions then:

- They worked 16-18 hours per day for fixed wages often below subsistence level.
- Even so, wages were often withheld for any waste or damage to raw materials.
- The Church backed the rich guild masters leading to a letter from the bishop declaring workers could be excommunicated for wasting wool.
- Resisting an employer could lead to prison, flogging, or even cutting off one's hand.
- Agitators for the right to organize were subject to hanging, 10 being hanged in 1345.

Wool carders are brushes used to comb through and straighten woolen fibers in preparation for later spinning and weaving.

In 1378, workers rioted and rushed the Signoria's palazzo and demanded the right to organize workers into their own guild, reform the

system of fines and punishments, and have a voice in Florence's government. The fearful town council gave in and a truly democratic government, led by Michele di Lando (left), was established which gave the Ciompi the right to organize their own guild.

However, the radical reforms of the Ciompi, frightened more moderate elements among the minor guilds, who aligned with the major guilds to undermine the new government, which crumbled after only 41 days. The Ciompi's reforms gradually eroded away until by 1382 the major guilds had reasserted their power. Scared by this event, the guilds were willing to submit to the strong rule of the Medici banking family.

The Jacquerie in 1358 was a spontaneous outburst of frustration by French peasants against the higher taxes that came from Plague & defeat in the Hundred Years War. Being spontaneous, as most peasant revolts were, the Jacquerie caught the nobles off guard and spread like "wildfire" across the countryside. Many towns also joined the rebels, often out of fear rather than sympathy, although Paris was involved in its own rebellion. However such revolts, being unplanned and poorly organized, were typically put down just as quickly. In this case, the turning point came when French knights returning from crusade encountered and massacred some rebels at the town of Meaux.

The leader of the uprising, Guillaume Cale (AKA Jacques Bonhomme) seems to have been a capable soldier who had forged the peasants into as much of an army as possible in such a short time. They made swords out of scythes and billhooks, armor from boiled leather, and even fashioned banners with the Fleur-de-lys motto "Montjoie" to show their loyalty to the king. In fact, peasant rebels commonly thought of themselves as loyal subject just trying to free the king from the power and influence of the nobles.

The decisive event in the revolt was the treacherous execution of Cale after being lured into a parley with the nobles. The excuse for going back on the promised safe conduct to Cale was that, as a peasant rebel, he wasn't a full

human being and didn't enjoy the privilege of a truce. Before beheading him (below), the nobles' leader, Charles the Bad of Navarre, added to Cale's pain and humiliation by crowning him with a red-hot circlet of iron.

As with most peasant revolts, the Jacquerie ended in massacre when the untrained and now leaderless rebels quickly broke and ran at the first charge by the nobles' cavalry. Punishment as always was swift and brutal. Often rebellious peasants were hanged, sometimes in their doorways as a warning to others who might be thinking about revolt.

The Wat Tyler rebellion broke out in England in 1381. The immediate causes were much the same as those of the *Jacquerie*: high war taxes, a recent outbreak of plague, and a resulting agricultural crisis. The course of events was also similar. The rebels advanced all the way to London, looting and pillaging as they came. They even managed to seize and murder several of the king's officials.

However, a daring ride in front of the rebels by the boy king, Richard II, who offered them concessions and supposedly his leadership in the revolt, settled them down. A parley was then arranged with the peasants' leader, Wat Tyler, which ended in his murder. This demoralized the peasants and allowed the nobles to defeat them and restore order in England much as the French nobles had in France.

However, despite their ultimate defeats, the popular revolts of the day had two important results. First, they damaged the nobles' military reputations and power and paved the way for the emergence of kings and the modern nation state. Secondly, workers' and peasants' wages did rise, also leading to a more even distribution of wealth.

WOMEN'S CHANGING STATUS IN LATE MEDIEVAL EUROPE

"Wives, submit yourselves unto your husbands as unto the Lord"--St. Paul

"...every reasonable man must prize, cherish, love woman...She is his mother, his sister, his friend; he must not treat her as an enemy."-- Christine de Pisan (b.1364)

Introduction. One of the major trends in Western societies over the last 150 years has been women's progress towards equal status with men. The roots of this lie in medieval Europe, although it is best to look separately at the three main social classes of middle class, peasants, and nobles, since they each told a different story.

Middle class women saw little or no gain, and maybe even a decline, in their status as town revived during the high and late Middle Ages. This was typical of pre-industrial towns, since most townspeople originally came from peasant backgrounds where the labor was more equitably shared, since every person's labor was critical for bringing in and processing the crops. When families moved to towns, the men typically became craftsmen who ran their own shops with little or no help from the women. This loss of economic status led to a corresponding loss of social status, and can be seen in practices across a number of pre-industrial urban cultures such as the wearing of veils, not just in Muslim, but also the ancient Greek society and foot binding in China. Women in urban societies were also married off at earlier ages and as pawns in family alliances, although this could happen among peasants as well. That being said, practices could vary a bit from country to country. For example, a woman in England could take over her husband's business after he died if he had no adult sons to succeed him. In general, however, urban living was no bargain as far as women's status was concerned.

Peasant women actually laid the firmest foundations for later gains in status. Part of this comes from the fact that they shared in the farm work and thus had status closer to that of their husbands than did their counterparts in town. This is typically overlooked because we have few written sources by or about women overall, and even fewer

for peasant women who were almost always illiterate (as were their husbands). However, in the 1300s, a colder climate and bubonic plague would improve their status in an unforeseen way.

People realized that overpopulation had made the disasters of the fourteenth century especially bad. Therefore, they made efforts to limit population growth so they didn't have to keep splitting up family lands until the plots were too small to support anyone. The primary method for this was to delay the age of marriage for both men and women. Men would typically wait until they could independently support themselves, which usually meant when their parents died or were too old to manage the family lands. Thus the multi-generational extended family of several generations living together under one roof gave way to the nuclear family of just parents and children in the household. However, most relatives still stayed in the same village or close by, thus providing the same basic safety net of support that extended families had provided for centuries. The real fragmentation into isolated nuclear families would not take place until the industrial revolution in the nineteenth century and the invention of the suburbs a century later.

Women also married later, which was especially critical to population control by restricting the number of active childbearing years. Thus women who previously might have married in their teens, now married in their twenties. However, women in their twenties were a bit harder to force into an arranged marriage than girls in their teens (despite what the behavior of the fourteen year old Juliet in Shakespeare's play might suggest).

Two bits of peasant culture support this. One is a common betrothal ceremony. When a couple had mutually agreed to get married, the man would approach the woman in the presence of neighbors and ask her if she were married, which everyone of course knew was not the case. He would then say he thought they should get married, and the crowd would agree. But then someone would say the prospective bride should have a say, to which everyone agreed. She would then assent to the marriage and they were betrothed.

Another bit of evidence comes from children's games, which typically mimic adult behavior. In

one game, a circle of girls protects one girl from the boys who are trying to break in and “marry” her. After the boys have tried to win the girl over with all sorts of promises, she chooses whom she will marry. The point in each of these examples is that peasant women in Western Europe had a say in whom they would marry, giving them more say in their lives than found in other cultures. Women would build on this status during the suffrage movement of the nineteenth and twentieth centuries.

Noble women, the courts of love, and the birth of “romance”. Women of the noble class underwent a very different sort of change in status. Their position in the warrior class gave them status over men for lower classes, but they were still subordinate to their husbands who almost exclusively did the fighting. However, the need for and value of warriors gradually started to drop as more settled conditions took over in the high Middle Ages. Meanwhile, there was a rising tide of piety, especially toward the Virgin Mary who symbolized a more gentle and merciful side of Christianity, and this was reflected on the esteem given to women overall.

One can see this reflected in the account of an Arab observer in the 12th century: *“The Franj (Franks, Western Europeans) have no sense of honor. If one of them is walking in the street with his wife and encounters another man, that man will take his wife's hand & draw her aside and speak to her, while the husband stands waiting for them to finish their conversation. If it lasts too long, he will leave her with her interlocutor & go off.”*

The scene shifts to Duke William IX of Aquitaine, father of one of the more assertive women of the age, Eleanor of Aquitaine. When Arab love poetry coming up from Spain was introduced to William’s court, it caught on, first with the duke and then with his subordinates. Following is a selection from one such poem:

*“A gazelle's are her eyes, sun-like is her splendor,
Like a sandhill her hips, like a bough her stature:
With tears I told her plaintively of my love for her,
And told her how much my pain made me suffer.
My heart met hers, knowing that love is contagious,
And that one deeply in love can transmit his
desire...”*

Traveling troubadours, who depended on the generosity of their hosts to make a living and previously had subsisted on stirring tales of battle, added these poems to their repertoire with great success, especially with the ladies of the household. In Southern France, where they started, they had to be careful not to make the songs too explicitly romantic with the man of the house right there. Therefore, at first, this was all very idealistic and non-physical in nature, but that changed when it spread to northern France and generated a new movement: the courts of love.

The courts of love were set up as a mirror image of regular courts. Whereas, in the king and nobles’ courts, men ruled by right of strength and power, and prowess in battle or tournaments was celebrated, in the courts of love, women presided and romantic virtues, poetic ability and good manners determined one’s place.

According to Andreas Coppelamus, an early writer on courtly love: *“Love is a certain inborn suffering derived from the sight of or excessive meditation upon the beauty of the opposite sex which causes each one to wish above all things the embraces of the other & by common desire to carry out all of love's precepts in the other's embraces.”*

Supposedly, a true lover never slept soundly, but always tossed & turned in bed. True love improved a man in every way. Fools became wise; klutzes became graceful & polished; cowards became heroes. It was even doubted whether a man who didn't truly love a woman could be a true knight. In fact, it was ideas like that last point that probably worked the courtly love ideals into the mainstream of society ruled by men.

The courts of love established strict rules on what true love is.

It was always between people of nearly equal social standing. Ironically it was supposedly acceptable for a noble to rape a peasant without losing his lady’s favor since peasants were considered incapable of feeling love.

It was always adulterous. The Church idea that sex was only for reproduction led to the belief that people so bound to each other couldn't love each other. Therefore, courtly love must be outside

marriage and one was not in fashion if one didn't have boyfriend or girlfriend outside of marriage.

It was always idealized & pure. This was a fairly new notion, considering love before was often spelled l-u-s-t (e.g., Ovid). With courtly love, the true test of love was for a couple to sleep together without doing anything but sleep.

It was religious in tone. This fit well with being idealized and pure, but hardly with the Church's stance on sex & love.

It was always secretive and expressed through sly glimpses, shadows of a smile and other signs of affection. Although it was best to keep one's extramarital affairs secret, women naturally wanted to advertise the attentions of other men to themselves. This led to a highly stylized ritual behavior where every word or action had significance.

It was always long lasting, faithful, & arduous, as seen in this story by Boccaccio:

"A knight who had offended his mistress was told, after two years of refusal, that if he would have one of his fingernails torn off & if 50 loving & faithful knights presented it to her, she might forgive him. He hastened to obey her. The nail was brought to her by 50 knights- all certified to be in the good grace of their ladies- resting on a velvet cushion. She was so touched by his obedience & commitment that she forgave him."

Of course this raises the question of how the ladies got the men to buy into this new code of behavior. For one thing, women did have higher status than before, and therefore more say in who received their favors.

One possible scenario may be that if one nobleman at court brushed his teeth and bathed regularly, talked about nice things rather than the latest foe he decapitated in battle, and used a handkerchief instead of his hand as the receptacle for blowing his nose, he must have gotten all the ladies' attention. Therefore, other guys would have to do the same if they wanted a date for Saturday night.

Since nobles set the tone for the rest of society, these new ideas about romance, everlasting love,

and chivalrous behavior toward women spread to the lower classes and became firmly embedded in our culture. Not until the later twentieth century would these values come under attack as being demeaning to women. However, if one considers the position women had been in before, this was a giant step forward.

Privacy in the Middle Ages? Forget it

A bishop blesses newly weds to ensure their fertility and ability to bear strong healthy children. This shows how marriage was a public as well as a private affair, since it bound two families and their fates together.

Our concept of privacy where we each have our own space, bedroom, or “man-cave”, is a very recent phenomenon. Before the Black Death, a European peasant family typically lived together in a one-room hut, slept together in the same bed, and even ate from the same plate. After the Black Death, when the survivors inherited the wealth of those who didn't survive, that changed a bit with people having their own beds, and plates. But togetherness was still more the rule than the exception.

Naturally, this was reflected in society, which even saw such personal things as marriage as public matters. The picture above with the bishop blessing a newly wed couple in their bed with the entire community present certainly illustrates this point. Even more to the point is the picture below of the groom escorting the wedding guests out of his bedroom to have some time alone with his bride. Their blissful moment of privacy won't last for long, however, as the guests will come storming back in, probably drunk, to make sure everything went well.

Even the concept of family encompassed a broader group of people than just close blood relatives. Peasant households before the Black Death would have extended families of multiple generations living under the same roof. Shortened lifespans meant there were always plenty of orphaned nephews, nieces, and cousins to take in, not to mention the occasionally disabled or elderly relative unable to live alone. Families could also be less stable and more diverse, as women might die in childbirth or men in fights or farming accidents, the surviving parent getting remarried, often to someone who was also widowed and with children, thus blending two unrelated families together.

The “families” of nobles and royalty would be even more extensive, with soldiers, officials, and servants filling up their households, maybe even spilling over into the lord’s bedroom. In the French monarchy, household officials, such as the seneschal, chamberlain, constable, and butler would expand their duties as royal officials as the Capetian Dynasty expanded its power across France.

Queens probably experienced the ultimate lack of privacy, especially at that most intimate of moments, giving birth. This was to make sure the queen didn’t substitute another baby (such as a boy for a girl) in order to fulfill her highest duty: producing a male heir to the throne. Failure to do so could lead to civil war over a disputed succession. Thus a queen found guilty of infidelity was charged with treason, since this cast doubt on the legitimacy of the chosen heir that might lead to civil conflict.

No one suffered from this custom more than Marie Antoinette, mainly because the first eight years of her marriage to Louis XVI had been childless and people were anxious for an

heir. Therefore, when she gave birth to her firstborn (which turned out to be a girl), her room was packed with spectators, including two chimney sweeps who climbed on top of the furniture for a better view. In fact the crush of people was so great that, if not for tapestries hung around the queen’s bed, she would have been literally buried in spectators during the blessed event. As it was, the heat of all those bodies probably contributed to her fainting after giving birth. Luckily a doctor was on hand to do a bloodletting to revive her. Amazingly she survived this ordeal.

After the Black Death, the extended family would be replaced by the nuclear, or “extended nuclear” family (since relatives still lived close to one another and largely functioned as a family unit). This provided a bit more privacy and opened the way for the emergence of the individual in the Renaissance. However, the level of privacy we are used to wouldn’t completely evolve until the twentieth century.

Women as Healers

Medieval medical tradition was strongly based on the theories of a second century physician, Galen. Since human dissections were frowned upon, he had to dissect animals, especially pigs, which he thought were closer to humans in terms of anatomy. Of course, he was often wrong in his assumptions about human anatomy based on that of pigs. But Galen had the force of tradition and support of the Church behind him, so his theories were generally accepted.

Medieval medical theory was also heavily based on Aristotle’s theory of four humors (blood, phlegm, black bile, and yellow bile)

which corresponded to the four terrestrial elements (air, water, earth, and fire). All sickness was seen as an internal imbalance of humors, not the result of outside factors. Thus all treatments had to do with restoring the balance by purging the excess humor through bleeding, enemas, or vomiting. However inaccurate this theory was, it was strongly backed by the Church and medical establishment, which consisted solely of men to the exclusion of women.

However, there was another completely separate and less publicized medical tradition: midwives. Throughout much of history these women were often the only healers available for women and poor people in general. Also, they usually knew as much, if not more, about herbal cures and anatomy than male doctors trained in the questionable traditions of ancient medicine.

Not that midwives didn't have their own superstitions using such things as hyena's feet, snake sloughs, canine placentas, sticks, and vulture feathers along with opening all the drawers and untying any knots in the house to ease the birthing process.

Midwifery has been the realm of women throughout history in most cultures such as the ancient Egyptians, Israelites, Greeks, Japanese, and Persians. Two Hebrew midwives Shifra and Puah, are even mentioned by name in the book of Exodus.

Luckily, many of the herbal cures these women learned through trial and error had applications beyond childbirth. Therefore, midwives often provided the only medical care that many or most people could get. This is even reflected in the contemporary novel, *The Hunger Games*. A study of Russian folk medicine showed that roughly half of its 400 herbal treatments were legitimate for at least relieving symptoms of an ailment, if not curing it.

From Midwives to Witches

Unfortunately, midwives/herbal healers had to be careful because their practices often ran counter to accepted theories of the medical establishment and Church. Also, since only women were involved in midwifery, the source of their knowledge was a mystery to men, who sometimes suspected they were witches practicing black magic and reacted by burning them at the stake.

The stereotype of witches as hags with disheveled hair and warts on their noses may also be partially rooted in fact. For one thing, many, maybe most, midwives were without male relatives, being single women or widows. Given the medieval corporate mentality of valuing people largely according to what group they belonged (family, guild, city, etc.), such women in essence belonged to no group having no families and being barred from citizenship and membership in the guilds. This also barred them from any profitable trades, forcing them into either prostitution or midwifery. Therefore, their isolation, by medieval standards, made them virtual nobodies. Below: Witches brewing up a storm.

Since their clientele were mostly women, who also had little money to spend, these midwives/herbal healers typically had to survive on very limited means in hovels at the edge of town or in the nearby woods. Not having access to hairdressers or nice clothes, they must have presented a somewhat ugly sight, even by medieval standards.

Likewise, their diets would consist of items not usually found on the tables of richer people in town (e.g., eye of newt). A common stereotype of witchcraft, the witch's brew, may have arisen from midwives' diets or because of their familiarity with different healing herbs that other people didn't understand.

Being so isolated, haggard, and mysterious, rumors of unsavory practices sprung up to fill in any gaps of knowledge about them. If something went particularly wrong, such as an epidemic, they could be convenient scapegoats and be charged as witches. By the same token, their greater success than real doctors in treating ailments might lead to such charges as well.

Even townswomen who knew them and used their services would be reluctant to defend them or even admit they knew them, since they might also be charged with witchcraft by association. Wives and daughters might also fear the wrath of their menfolk if they were to find out their women had been using such services.

Keep in mind that the lives of men and women intersected much less than now, so men were much more in the dark about midwives and the world of women in general, and would tend to be more suspicious of their mysterious practices.

As the Florentine proverb put it: "*A good woman and bad one require equally the stick.*" Such treatment must have constantly been in the forefront of women's minds when deciding what they could safely tell their husbands.

The Perils of Womanhood

Old man and Maid by David Teniers. Notice they aren't alone as someone, presumably the old man's wife, is watching from the upper left.

Sexual harassment is nothing new to our times. In medieval and early modern times teenage girls from poorer homes typically would work as domestic servants for richer families to supplement their own families' income. Being poor, young, and female, they were especially vulnerable to attentions of their employers. It was often a lose-lose situation for them, since, if they went along and got pregnant, they would get fired, and if they didn't go along, they also might get fired.

Complicating matters was the Church practice of sanctioning secret marriages done by clergy but without the parents' consent or knowledge. While this enhanced the Church's prestige at the expense of the family, its secretive nature and the absence of public witnesses led to lawsuits over whether the father was actually married to the mother. If the father admitted to being secretly married to her by the Church, the civil courts would also declare him married. If he denied being married, he judged a fornicator and had to pay twice the normal dowry to the mother, since she was now considered less marriageable. In disputed cases that remained unresolved, the courts usually ruled in the woman's favor, assuming she had been seduced and/or forced into the relationship. To avoid more of these disputes, towns started requiring public weddings before witnesses.

Another unfortunate practice involving young women was prostitution. Contrary to many male fantasies, women did not enter “the world’s oldest profession” because it offered loads of fun and exciting career opportunities. Rather, it was typically an act of desperation driven by poverty, and even fathers desperate for money. Farmers might also bring their daughters into town to sell their services, especially during trade fairs when business was particularly good.

Since the age of marriage for young townsmen was commonly the mid to late twenties, towns actually kept brothels in order to control or channel their wilder testosterone driven tendencies and minimize street violence. However, tighter moral standards emerging from both the Protestant and Catholic Reformations along with the spread of syphilis in the 1500s led to a movement to close these brothels after 1550. This wasn’t necessarily good news for women, since prostitution continued, but without the protection from violence by the state.

The perils facing young unmarried women inspired the following testament from a dying mother to her daughter in the 1600s:
“Don’t eat and drink too much at parties. Eat and drink ahead of time and accept drinks only from other girls. If a boy peels a fruit for you, do not accept it. When boys come and sit beside you, don’t answer their questions; say only “yes,” “no,” and “I don’t know.” And do not smile at them. When boys happen to come into your bedroom, hide behind the bed and threaten to hit them in the face.”

SCHISM AND HERESY: THE DECLINE OF THE CHURCH (c.1300-1450)

The Avignon Papacy or "Babylonian Captivity" (1309-77). The Later Middle Ages were a time of turmoil for the Catholic Church, as the growing power of kings and popes in the High Middle Ages led to rising tensions over various forms of authority and jurisdiction. Although they had largely won their struggle with the emperors in Germany, the popes were less successful in dealing with the rising power of the French and English monarchies. Problems centered on control of two things: the local clergy and Church taxes. The popes had a habit of rewarding their Italian supporters with church offices all across Europe. Both common people and local native clergy resented this and looked to the king for help against these Italian clergy. As a result, the popes found much of their own local clergy aligned against them and with the kings.

Meanwhile, during their struggle with the Holy Roman Empire, the popes had granted kings the right to collect church taxes in return for aid against the German rulers, justifying their actions by declaring these wars crusades. But when war broke out in 1294 between France and England, both countries' kings used the precedent of collecting church taxes for the popes' wars to justify collecting church taxes for their own wars. When Pope Boniface VIII refused to let Philip IV of France do this, Philip and his agent, Nogaret, planned to subject the pope to the inquisition for crimes he allegedly had committed. When this plan failed, Nogaret and the pope's enemies in Rome kidnapped Boniface. Although he was soon rescued by loyal followers, he died a few days later.

Among the charges brought against Boniface, who was 86 years old at the time, were blasphemy, murder, sorcery, and consorting with a familiar spirit (pet demon).

The College of Cardinals, probably feeling pressure from the highhanded acts of the French king and his agents, elected a Frenchman, Clement V, as the new pope. Clement set out for Rome, but never made it there, stopping at Avignon, a papal city close to French territory. For the next 70 years (1309-77), the popes, all of who were French born, stayed in Avignon. During this period (known as the

Babylonian Captivity after the 70 years of captivity the Old Testament Jews had spent in Babylon), the popes came under increasing criticism for being corrupt and under the thumb of the French kings. Whatever the truth of these charges, the Avignon papacy symbolized the decline of the medieval papacy. The kings' increasing ability to claim the loyalty of the local clergy and to collect church taxes helped create several quasi-national churches that officially were part of the Roman Catholic Church but were increasingly under royal control. The Babylonian Captivity, along with the Hundred Years War then going on, also triggered challenges to papal authority from two other directions: church councils and popular heresies.

The scholar, Petrarch, called Avignon the "Babylon of the West."

The Great Schism and Conciliar movement. The resentment that the Babylonian Captivity aroused against the Church worsened when the pope tried to move back to Rome. By the 1370's, the turmoil of the Hundred Years War was making life at Avignon increasingly dangerous. The capture and ransoming of Pope Innocent VI by a company of English mercenaries (who had little use for a French pope, anyway) convinced Gregory XI to move to Rome. However, Rome was a more dangerous place to live in during times of "peace" than France was during war. It took Gregory three tries to get into Rome, and once he got in, he quickly decided he wanted to leave and return to Avignon. Unfortunately, Gregory died before he could get out.

For the first time in 70 years, Rome was the scene of a papal election, and the Roman mob clamored outside for an Italian pope. Under such pressure, the College of Cardinals elected an Italian, Urban VI, as the next pope. Unfortunately, Urban was something of a violent and bigoted man whose actions drove all but three cardinals back to Avignon where they elected a second pope. Thus began the Great Schism, a period of turmoil when the Church was divided in its loyalty between two lines of popes, one French and one Italian. To no one's surprise, each pope refused to recognize the other and even excommunicated him and his followers. This led to enormous anxiety among devout Christians, who found themselves supposedly excommunicated by one pope or the

other. With neither pope willing to resign, something had to be done.

The most popular suggestion was a general church council such as the ones summoned to solve major disputes in the past. There were several problems with this solution. First of all, popes traditionally called such councils, and neither pope was willing to call such a council. This made the legality of such a council questionable if not called by at least one pope. Second, different rulers in Europe supported particular popes, largely for political reasons. Such political divisions made it almost impossible to get people to agree on the site of a council, not to mention the deeper issues involved. Finally, the whole issue of a Church council raised the question: if a council could depose the pope, who was the real head of the Church? This was a question that lingered on long after the Great Schism had faded away.

At last, a council was called at Pisa, Italy in 1409. It deposed the two rival popes and elected a third. Unfortunately, neither original pope recognized the council's power to depose a pope, so now the Church had *three* popes.

When the third pope died, he was succeeded by John XXIII, often called an anti-pope, who was so corrupt that no pope took the name John until the 1950s. Among his scams was a plan to pack the next Church council at Constance with his own followers by creating lots of new Italian bishops. However, he was thwarted by a rule that each nation got only one vote. John then tried to flee before the council could depose him, but was captured, deposed and imprisoned. However, the next pope freed him and made him a cardinal. He died soon after and was buried in the Baptistry of Florence.

However, by this time, people were committed to the idea of a church council, and another one was called at Constance, Switzerland. All three popes were deposed, and a fourth, Martin V, was elected. Although one of the deposed popes held on in Avignon until 1429, the Great Schism ended here. Its effects did not, because it caused people all over Western Europe to question the authority of the pope in the Church. Although a single pope once

again ruled the Church, his reputation and authority were permanently undermined.

The challenge from below: the Lollard and Hussite heresies. Besides discontent within the ranks of the clergy, the Babylonian Captivity also caused popular discontent in the form of heresies. During the Hundred Years War, the French popes at Avignon were especially unpopular in England, and it was here that the first of these heresies emerged. Its leader was an Oxford scholar, John Wycliffe (called Wicked Life by his enemies). His main point was that the *Bible* is the sole source of religious truth, and therefore anything not in the *Bible* did not belong in the Christian faith or practice. In Wycliffe's view this meant that such mainstays of Catholic practice as confession, penance, pilgrimages, veneration of saintly relics, excommunication, Church ownership of property, and the gap in status between the clergy and laity (non-clergy) should all be abolished since there was no mention of them in the *Bible*.

Possibly Wycliffe's most revolutionary act was translating the Latin Vulgate *Bible* into English so the common people could read it for themselves. Such an act made it much more difficult for the Church to keep its monopoly on religious truth. It also led to a variety of interpretations of the *Bible* by some of Wycliffe's followers known as Lollards (meaning mumblers or babblers). The more radical Lollards did such things as chopping up images of saints for firewood, holding mock masses, and eating communion bread with onions to show it was no different from regular bread.

Because of England's hostility to the French and the popes at Avignon, initial reaction to the Lollards was mild until the Wat Tyler Rebellion broke out in 1381. After that, the authorities were much sterner with the heresy, burning some fifty Lollards at the stake over the next 40 years. Wycliffe himself was mildly reprimanded. He died peacefully in 1384. However, his heresy did not.

Among the Lollards were a number of influential people, including Queen Anne, who came from Bohemia (modern Czech Republic). She sent several copies of Wycliffe's writings home where the heresy caught on. In addition to this heresy, there was also a growing national consciousness among the Bohemians aimed mainly against the

German ruling class. This combination of heresy and a growing national consciousness would prove to be a devastating force in the events about to unfold.

Public sermons in the streets of Prague criticized Church corruption while translators produced 33 handwritten copies of the *Bible* in the Czech language. At the center of all this turmoil was Jan Hus, a popular preacher and professor who was heavily influenced by Wycliffe. Hus' writing and preaching stirred up more and more anti-church and anti-German feeling. This led to a condemnation of Hus' works, which in turn provoked a wave of riots and protests across Bohemia. Faced with the possibility of a full-scale rebellion against the Church, the pope and the Council of Constance summoned Hus, under promise of a safe conduct, to defend his views. The council unwisely went back on its word, had Hus declared a heretic, and burned him at the stake. Rather than depriving the Bohemians of a leader, this act provided them with a martyr around whom they could rally. The resulting Hussite Wars (1420-36) showed how powerful a combination nationalist feeling and popular piety could be.

The Church's excuse for going back on its promise of safe conduct to Hus was that as a heretic, he was not worthy of having oaths made to him being kept.

The Church launched five crusades against the Hussites, all of them dismal failures. The Hussites combined new firearms technology with the ancient Bohemian tactic of making circular walls of wagons (*wagenburgs*) to create a seemingly invincible army. Hussite armies even invaded Germany, plundering at will all the way to the Baltic Sea. By 1433, the Church had had enough and opened negotiations with the Hussites to keep them from spreading their heresy across Europe. The Hussites, not ready for a complete break with the Catholic Church that had led the faith for centuries, were also willing to compromise. The Church allowed certain religious liberties in return for the Hussites' allegiance to the Church.

Although the Hussites had returned to the Church, their importance lived on. For, just across the border in Saxony some 85 years later, another reformer by the name of Martin Luther would lead

another revolt against the Church, raising many of the same points Wycliffe and the Hussites had raised. Only this time, the break, known as the Protestant Reformation, would be permanent and alter the course of European and world history.

Hussite Warfare

The Hussite army on the march. The chalice on the banners signifies their demand to be given wine as well as bread at communion. The Church would only let clergy have the wine, fearing the laity would spill it, thus spilling Christ's blood.

Hussite armies were a perfect example of the transition from the medieval to modern worlds, using an ancient Slavic formation, the *wagenberg* (wagon-fort), along with firearms to break up enemy cavalry charges. Sometimes, *wagenbergs* would be left open, but arranged internally in the form of a maze, so enemy cavalry would charge in and get lost. Hussites on the surrounding wagons could then attack them with guns and flails while they tried to find their way out.

An estimated 1/3 Hussite soldiers were armed with a very early type of firearms (above). It took two people to handle one of these guns: one to hold and aim it and the other to light the fuse to fire it. Such guns took a long time to load and fire and were quite inaccurate. But they could pierce cavalry armor and scare enemy horses not used to their loud noise.

THE HUNDRED YEARS WAR AND THE EMERGENCE OF THE FRENCH AND ENGLISH NATIONS (1337-1453)

Introduction. Nothing better epitomizes the turmoil of the Later Middle Ages than the prolonged and desperate struggle between France and England known as the Hundred Years War. Technically, this was a series of wars intermittently separated by periods of uneasy peace, but the fact that it took over a century to resolve this struggle justifies treating it as one war. Although, on the surface, the issues involved just concerned who held certain territories and the French throne, there were deeper processes going on that gave this struggle an importance far beyond its battles. The main process taking place was the painful separation of the two nations from a feudal and dynastic concept of the state that had kept French and English histories intertwined with one another since the Norman conquest of England in 1066. The growing use of the English language throughout the war especially illustrated this process. Whereas French was the primary language of the English court at the start of the war, by the end it was English. Also, Geoffrey Chaucer had written *Canterbury Tales*, one of the first great works of English literature, and John Wycliffe had translated the *Bible* into English, all this showing a growing sense of an English nation and culture.

Causes. Probably the greatest problem was England's control of Gascony (AKA Guyenne), a rich wine producing area in southwestern France with close trade ties to England. Since 1259 the English king had held this province as the French king's vassal, and herein lay the problem. It was humiliating for the sovereign king of England to have to do homage to the French king as his overlord, especially when the latter would arbitrarily use his position as the English king's overlord in any disputes between the two. Gascony had already been at the center of two previous wars between France and England in 1294-98 and 1324-27. Therefore, the Hundred Years War can be viewed as part of this deep-seated dispute. To complicate the situation, the Gascons (who spoke Gascon, not French) preferred the English kings' lighter rule to that of the French king. Even the French historian of the war, Froissart, would often refer to the Gascons as "the English", since they

joined the English raids on France and defended Gascony against the French with minimal help from England throughout the war.

Both sides supported independence movements by the others' subjects. England, which had strong trade ties with Flanders, favored the Flemish towns' rebellion against France and the Count of Flanders, which had produced the shocking defeat of French chivalry at Courtrai in 1302. Likewise, France supported Scottish revolts against England, which suffered a humiliating defeat at Bannockburn in 1314. Although both kingdoms avenged these defeats and reasserted their rule over the rebels, they each had to keep a vigilant eye on affairs closer to home while dealing with their rivals across the Channel.

Then there was Edward III of England's claim to the throne of France. Edward was the son of Edward II of England and Isabella, the daughter of the French king, Philip IV. Since Philip had three sons, this marriage seemed to pose little danger of making an English king heir to the French throne. However, as luck would have it, all three of Philip's sons (Louis X, Philip V, and Charles IV), ruled without leaving a male heir. When Charles died in 1328, Edward III of England was the only living male descendant of Philip IV.

To counter Edward's claim, Philip's nephew, also named Philip, invoked an old law code, known as Salic Law, that said the French throne could not be passed through the female line of the royal family. The French lawyers and nobles, not wanting the strong and energetic Edward ruling over them, chose Charles' first cousin who assumed the French crown as Philip VI.

Historians have made much of Edward's claim to the French throne, more than Edward seems to have done. Despite a number of disputes with Philip VI, Edward never put forth his claim to be king of France until 1340, making it seem more a result, rather than cause, of the war. Ironically, English kings would still claim the title of king of France all the way to 1801.

The new face of war. One of the most dramatic signs of the transition from the medieval to modern world was the changing nature of warfare. The English were especially innovative in this regard,

probably because they faced a much larger and more powerful enemy and thus felt more of a need to experiment with new ways of fighting. The armies of the Hundred Years War would differ from the armies of the Dark Ages in three major ways. One change was that, for the most part, these were not feudal armies of noble vassals fighting to fulfill their personal obligations to their lords. Rather, they were largely collections of mercenary companies containing many members of the lower classes and even criminal element. Their captains would contract their services to a king in return for the promise of pay, plunder, and ransoms for any captured enemies. Such armies may have been more stable and reliable than the old feudal armies, but they also created serious problems. Since they were rarely paid in full or on time and their ranks were often filled with the more disreputable types in society, they were prone to desertion, plundering, and violence against the civilian populace.

Two other big changes had to do with weaponry. One was the longbow, adopted from the Welsh by Edward I in the late 1200's. This was a specialized weapon that took a full year to make and years to master. As a result, only richer free peasants (yeomen) and professional mercenaries had the leisure time for practice. The longbow was both powerful and had a rapid rate of fire. Formations of English long-bowmen, protected by rows of sharpened stakes and intervening formations of English knights, could unleash ten to twelve volleys of arrows per minute, a devastating rate of fire as the French would find out. Another weapon that would assume greater importance as the war continued was gunpowder. Both the English and, later on, the French would use cannons effectively to demolish castle walls and the medieval order they stood for.

While the history of the war was long and involved, it followed a basic pattern. At first, the English, with strong leaders and new weapons and tactics, would win striking victories against much larger French armies. This would continue until weak leaders would take power in England and more decisive one would take over in France. Then the French would adapt to the English weapons and tactics and gradually recover their lands. However, England would once again see strong leaders while France would suffer weak ones again and the pattern would start all over. This pattern cycled

around two times, dividing the war into four basic phases.

Phase I: England ascendant 1337-1369. The first major battle of the war, Sluys (1340), was a naval battle and determined who would control the English Channel. Naval battles in the Atlantic were rare, since the seas were too rough for oar driven galleys, and the square sail then in use could not tack well into the wind. Therefore, one navy or the other was usually confined to port, depending on the wind. Without the use of oars, ramming and clipping enemy ships was impractical, so naval battles were mainly land battles fought at sea, with each side trying to grapple and board the other side's ships. In such a battle, the English had a definite advantage, since their longbows provided the firepower to clear enemy decks and let English soldiers storm their ships. As a result, the Battle of Sluys was a decisive victory for the English and gave them the freedom to raid France while securing their own coasts from seaborne raids.

For several years, small English armies would raid and plunder French territory while being careful to avoid any large French forces, since the English themselves were not sure of how effective their longbows would be against French knights. However, in 1346 a large French army succeeded in cornering a much smaller English army and forcing it to fight at Crecy. Lined up behind protective wooden stakes, the English long-bowmen launched volley after volley of arrows as "thick as snow", first mowing down enemy crossbowmen and then bringing succeeding waves of charging French knights crashing to the ground. By sundown, the English had won a stunning victory against what seemed like insurmountable odds, considering enemy numbers and the high regard in which French knights were held all over Europe. Crecy opened the French countryside to the English, allowing them to seize the port of Calais, which they held until the 1550's.

However, the French refused to recognize that the outcome at Crecy using these new tactics of long-bowmen in coordination with knights was anything besides a fluke. Therefore, after an interlude in the fighting brought on by the Black Death, they went after the English army again. This time they tracked down Edward the Black Prince and an army of some 8000 men at Poitiers (1356). Once again

the French knights charged the English lines, and once again the hissing volleys of English arrows littered the field with French dead and wounded. Among the numerous prisoners held for ransom was the French king. Poitiers confirmed Crecy's verdict that the balance of power on the battlefields of Europe was clearly shifting away from the heavily armored knight.

The aftermath of Poitiers saw the English conquer large areas of France in the western coastal areas. Meanwhile, peasant revolts, such as the Jacquerie, were challenging new taxes and the nobles' power in society. Given all this turmoil and their inability to beat English armies, the French concluded the Treaty of Bretigny in 1360, recognizing Edward's new conquests in return for his relinquishing any claim to the French crown.

However, peace did not return to France, because the English did not want to disband their so-called free companies of mercenaries in England where they could raise all sorts of havoc. Instead, they turned them loose in France where they continued to loot and pillage as if peace had never been signed. One free company made a living from capturing castles and then selling them back to their original owners. Another company, under Sir Robert Knollys (knighted by Edward for his exploits and atrocities in France), controlled forty castles and plundered at will from Orleans to Vezelay. In response to these ravages, French peasants fortified their churches, slept on islands in local rivers, and dug tunnels to escape the English. Seeing no apparent difference between peace and war, the French resumed the war in 1369.

Phase II: The French resurgence (1369-1413). By now, the French had learned to avoid open battle against the English long-bowmen, choosing instead to bolster town and castle fortification, cut off any isolated raiding parties, and deny the English the plunder that made the war worthwhile to them. Thanks to this strategy, the French recovered most of their lands from the English. This, the return of the Black Death, and then the Wat Tyler rebellion in 1381 all combined to make the war very unpopular in England. Therefore, in 1396, it was the English turn to ask for peace, giving up most of their French possessions in the process.

However, the tide soon turned back to favor the English for a couple reasons. First of all, the rule of the mentally unstable French king, Charles VI (1380-1422), unleashed factional strife between the noble houses of Orleans and Burgundy over who would control the king and French policies. Therefore, France was in a state of turmoil and open to attack. Also, about this time, a warlike English king, Henry V, took the throne and decided to launch a new campaign in France.

The English resurgence (1413-1428). Henry entered France with a small army of 1000 knights and 6000 long-bowmen. Like Edward III and the Black Prince before him, Henry was trapped by a much larger French army that forced his tired and hungry army to fight at Agincourt (1415). By this time, knights were wearing suits of plate armor weighing up to 65 pounds, a much harder shell for the longbow arrows to penetrate. Despite this, the longbow still played a vital role in winning Agincourt. For whatever reasons, the French chose to avoid the formations of long-bowmen and instead attacked the groups of English knights in between. This had the effect of cramming the French into ever-narrower spaces that gave them no room to raise their weapons. Meanwhile, their comrades in back, unaware of this, kept pushing forward, creating even more of a crush up front that the English knights exploited mercilessly. At the same time, the English long-bowmen were hitting the French from the sides. This combination of being unable to maneuver and being attacked from three sides made Agincourt as much of a disaster for the French as Crecy and Poitiers had been.

Agincourt unleashed an avalanche of misfortunes upon France. The Duke of Burgundy, bitter over the murder of his father by the Duke of Orleans, defected to the English side. Paris fell to the enemy, while famine and turmoil stalked the land. Equally decisive and portentous for the future was another new weapon that was changing the face of warfare: gunpowder. Cannons had been used as early as Crecy in 1346, but mainly as glorified noisemakers. However, by the early 1400's, the English had a large and effective siege train of cannons that pulverized the old medieval fortifications of towns and castles. By 1420, the English and their Burgundian allies had control of the northern half of France, forcing the French to agree to the Treaty of Troyes, by which Henry

would take the French throne after Charles VI died. However, Henry died shortly before Charles and was succeeded by the infant, Henry VI. The French refused to give the throne to this child, and war resumed.

Joan of Arc and the final French triumph (1428-53). At first, the Duke of Bedford, regent for the young Henry VI, ably continued the English advance against the pale and feeble Charles VII. It was then that a remarkable peasant girl, known to history as Joan of Arc, came to the French court, claiming divine voices had told her to lead France to victory. Despite the snickering at this simple peasant girl by the court, her persistence and genuine faith in her mission persuaded Charles to let her accompany the French army trying to relieve the city of Orleans. For whatever reasons, the French succeeded in saving Orleans, thus opening the road to Reims where Charles could officially be crowned.

To the soldiers, Joan was a symbol of French defiance, and her example restored the army's spirit. However, her luck soon ran out. In 1430, the Burgundians captured Joan and sold her to the English who tried her as a witch for hearing demonic voices. After a long and exhausting trial, she was convicted by a French church court and burned at the stake in the market place of Rouen in 1431. Years later the Church would reverse its decision and declare Joan a saint. She was only 19 years old when she died.

Joan's death backfired against the English in much the same way as the execution of the Hussite leader, Jan Hus, had backfired against the Church a few years before. Charles VII took heart and led a vigorous offensive against the English, while the French people agreed to a war tax to pay for soldiers and artillery to free their land of the now hated English. Now it was the French turn to use cannons to demolish English fortifications and sweep through France. Meanwhile, high war taxes and the lack of plunder to pay for the war made it increasingly unpopular in England. As a result, Parliament cut most funds for fighting in France. In 1451, at the Battle of Castillon, the French, using another experimental weapon, primitive firearms, defeated the last English army in France. Two years later in 1453, the same year the Ottoman Turks used artillery to help them storm the walls of

Constantinople, the English were out of France except for the port of Calais. The Hundred Years War was over.

Conclusion. What had all this accomplished? The main significance of the Hundred Years War was that France and England, bound together for centuries by outmoded feudal ties and concepts, were now wrenched apart, leaving in their wake two distinct nations free to follow their own destinies. The Hundred Years War also symbolized far reaching military and social changes. Although nobles would be around for centuries to come, the longbow and gunpowder showed that their days were numbered. Gunpowder in particular meant that nobles were no longer safe, either on the battlefield or behind their own castle walls. And with their military dominance went the nobles' unchallenged social preeminence. Gunpowder technology was also expensive. As a result, only kings and princes were able to afford armies with cannons and firearms, thus stripping nobles of even more of their power and prestige, leaving the way open for the rise of the modern nation state.

Psychos and “Soldier Riots”: The New Face of War

“War without fire is like sausage without mustard.”—Henry V of England

English mercenaries burn a French village in *The Messenger*, one of the most brutally realistic films about Joan of Arc and the Hundred Years War.

Nothing more dramatically showed the transition from the medieval to modern world than the changing nature of warfare. The English, who faced a much larger and more powerful enemy were especially innovative in this regard.

However, these were no longer just feudal armies of noble vassals fighting to fulfill personal obligations to their lords. Rather, they were mostly collections of mercenary companies drawn from the lower classes and even criminal element. In fact, one study indicates 12% of the English soldiers were condemned criminals, choosing military service over the executioner's axe.

Captains would contract their companies' services to a king in return for the promise of pay, plunder, and ransoms for any captured enemies. Such armies may have been more stable and reliable than the old feudal armies, but they also created serious problems. Since they were rarely paid in full or on time and their ranks were often filled with the more disreputable types in society, they were prone to desertion, plundering, and violence against the civilian populace.

However, the brutal attitude of these soldiers suited the English leaders, who planned to wear down and break the French through a series of *chevauchees*: raids intended to completely devastate the countryside. Soldiers would torture the men to reveal where they kept their valuables, mutilate and rape the women, even the pregnant ones, and murder the rest they could catch. Not even the clergy were exempt from such treatment. When a French archbishop was taken to the top of a tower to witness the countryside in flames as far as he could see, he fainted from shock.

Even worse, during times of "peace" when the mercenaries were without employment, many of them, both French & English, would organize into companies known as *routiers* & continue to ravage the countryside. Making this especially bad was the fact that, in contrast to wartime when these men were under at least some level of restraint by their commanders, during peacetime there was not even that much restraint on their behavior. No wonder that by the end of the war, the French would refer to the English as the Godoms ("God damns")

Psychos and "soldier riots." A particularly brutal and psychotic mercenary (above) closes in to murder and rape a French girl in *The Messenger*. Most soldiers in history weren't as crazy as this one, being more interested in food and plunder than gratuitous violence. However, they were generally unwilling to get in the way of the occasional psycho that would be in their units. Unfortunately, in the absence of any discipline from above, more and more "normal" soldiers would get pulled in to a spiraling orgy of violence until it reached epidemic proportions with tragic results for the civilian population.

Such "soldier riots", for lack of a better term, have occurred repeatedly throughout history and can be seen as an especially brutal variant on mob violence, the difference being they are carried out by trained killers who are already heavily armed. Just a few of the more notorious examples from twentieth century history were Nazi atrocities (in particular against Slavic peoples in Eastern Europe, the "Rape of Nanking" by the Japanese in World War II, and the massacre of Vietnamese civilians at My Lai by American soldiers.

Longbows and cannons. There were also big changes in weaponry. One was the longbow, adopted from the Welsh by Edward I in the late 1200's. This was a specialized weapon that took a full year to make and years to master. As a result, only richer free peasants (yeomen) and professional mercenaries had the leisure time for practice.

The longbow had both power and a rapid rate of fire. Formations of English long-bowmen, protected by rows of sharpened stakes and intervening formations of English knights, could unleash 10 arrows a minute up to a range of 150 meters, piercing plate armor at 60 meters.

In contrast, the crossbow, favored by the French had a greater range and required little training (making it a popular weapon among town militia), but it weighed 20 pounds and could only be fired 2 times a minute.

English long-bowmen may have used “time on target” firing where the ranks fired in sequence from back to front so that all the arrows fell at once. Such a technique could have devastating psychological effects, since there seemed to be nowhere to escape.

American artillery in World War I used the same technique against the Germans. Women, known as *computers* were hired in order to calculate the respective firing times for different lines of artillery. Later in the war, this process was automated by a new type of electronic calculator, which also became known as the computer.

Different types of arrowheads were used for different purposes. From left to right: a general-purpose point, armor-piercing bodkin point, chainmail-piercing point, and a hunting point used against unprotected horses.

As decreed by the king, English yeomen (richer peasants) would practice “at the butts” on Sunday afternoons. This is what produced the strength and training necessary for England to have the large numbers of skilled long-bowmen it used in France. The

French had no comparable system for training long-bowmen, so had to rely on slower and heavier crossbows. In addition to long-bowmen, English armies had numbers of very nimble Welsh infantry armed with long knives who would sneak under horses to cut their bellies or looked for wounded soldiers to kill and strip.

The other innovation decisively affecting the Hundred Years War was combining gunpowder with the cannon. At first, cannons fired stone balls chiseled to fit into the cannon barrel. These were soon replaced by cast iron cannonballs that pulverized castles’ tall thin walls.

However this new technology could be as hazardous to its users as its intended victims. Gunpowder was of uneven quality, so one never knew how big a charge was being loaded. That, along with poor casting, could cause the barrel to explode upon firing. After the siege of Cherbourg, the French king congratulated his gunsmith for only four of his cannons blowing up during the operation.

First Blood at Sluys (1340)

English and French clash at Sluys, the first major engagement of the war.

Where this war was fought depended on who could control the English Channel and take the war to the enemy’s land. Thus the first major clash in the Hundred Years War was a naval battle.

Naval battles were fought like land battles, with each side trying to board and take over the enemy ships. With nowhere to run, such battles could be especially fierce and desperate. However, naval battles were rare in the North Atlantic with its strong winds, since the square sails in use severely limited tacking into the wind and typically confined one navy or another to port.

The English fought in groups of 3 ships, two with long-bowmen and one with men-at-arms. The archers would clear the enemy decks so their men at arms could storm aboard their ships.

The French did have a number of Genoese oared galleys with rams that would favor them in a battle in open waters. However, they chose instead to form three lines of ships lashed together in an estuary, allowing the English to get upwind of them and wait for the tide to turn. Then, with the wind, tide and sun at their backs, they crashed into the French ships, pouring volleys of arrows into their ranks at five times the firing rate of enemy crossbowmen.

The first wave of French threw both their wounded and themselves overboard. When the French admiral was captured and hanged, the second wave panicked and also jumped overboard. At that point the battle became a massacre with bodies covering the water and the decks of French ships.

The light from the burning ships was so bright that the slaughter continued into the night, with only 30 French ships escaping this disaster. It was said that if fish could talk, they'd speak French from all the French blood they drank.

Obviously, no one wanted to break the news to the king, so they had the court jester run in yelling: "*Oh the cowardly English, the cowardly English! They don't jump in the water like our brave Frenchmen.*" The king got the message and the English now had control of the Channel and a foothold in France.

The Longbow Proves its Worth at Crecy

For several years after the battle of Sluys, French and English armies raided each other's territories in France, but did little in the way of fighting. Then, in 1346, Edward III's son, Edward, known as the Black Prince for the color of his German armor, led a particularly daring and destructive raid. This time the French army went in pursuit and trapped a much smaller English army near the town of Crecy.

The English took up a strong position on a hill and arranged their army in alternate groups of bowmen and knights. The French camped so far from the English that they didn't arrive until 4 PM with the sun in their faces. The French king wanted to stop and attack the next morning, but his huge army kept pressing forward until it drove the front ranks to within sight of the English.

Therefore, the French nobles felt that honor dictated they charge immediately.

Genoese crossbowmen opened the attack for the French. However, a sudden storm had soaked their crossbow strings, while the English had coiled theirs under their helmets. This forced the Genoese to approach the enemy lines closer than usual. Suddenly, before they could get in range they came under storm of arrows "as thick as snow". Having discarded their heavy shields (pavises) on the march, they had no protection, so they immediately broke and ran.

At this, the French cavalry charged, slashing and cutting through their own retreating men. Hearing the screams of the Genoese, the French in the rear thought it was the English

screaming and pressed forward to share in the glory and plunder.

This just created a densely packed mob at the foot of the slope, making it nearly impossible for the long-bowmen to miss their mark. French horses that were hit bolted in panic increasing the chaos in the ranks. Horses piled on top of horses “like a litter of piglets”.

Some French reached the English men at arms, only to be cut down. Among them was, John, the blind king of Bohemia who charged with his reins tied to those of horses flanking him. Prince Edward was so moved by the blind king’s bravery, that he adopted his motto: Ich dien (I serve) for his own coat of arms.

The French launched 15 waves well into the night, all of which faltered and broke under the murderous rain of arrows. Finally, the English advanced on foot into the carnage to finish off the wounded. One estimate put French losses at 10,000 men. When the French king left the field, he could only find 60 knights to accompany him. The rest had died or fled.

Everyone, including the English, was stunned by the scope of their victory. The French, reputedly the bravest and fiercest warriors in Europe, had been cut to pieces by a much smaller army consisting mainly of lowly archers.

Crecy led to the capture of several coastal cities. The most important of these, Calais, would serve the English as their primary base of operations to the end of the war. Edward turned out its people and repopulated it with English settlers, making it a little bit of England under the jurisdiction of the Archbishop of Canterbury for the next 200 years. They would hold Calais until 1558.

Another Disaster at Poitiers (1356)

By 1356, Europe had recovered sufficiently from the shock of the Plague to resume normal activities, including warfare. Edward the Black Prince launched another devastating *chevauchee*, a 600-mile march of total destruction that only spared those rich enough to be ransomed while killing all the rest. The baggage train groaned beneath the weight of all the plunder, but the English also suffered from the French scorched earth policy to deny them provisions.

The battle opened with 300 picked French knights charging on horse, but the English long-bowmen easily brought down their horses. Then the rest of the French knights, 13,000 of them arranged in three waves, advanced in full armor on foot, probably to protect their horses from English arrows. However, the march was across a muddy field, which wore them out before they even reached the English.

Once the French were within range, the English unleashed a hail of arrows so thick that they darkened the sky. Still, the first wave reached the English lines and a savage hand-to-hand battle ensued. However, when the English threatened to capture the French king, the first wave retreated and ran into the second wave, which panicked and ran without even fighting.

The third French wave now advanced against the battered & exhausted English army whose archers had to retrieve arrows from the battlefield or throw stones. Finally, they joined in the melee with axes & spears. The fighting was so fierce that it was heard in Poitiers seven miles away.

With the battle hanging in the balance, Edward attacked the French king’s battalion with his

last reserves, sneaking from behind. This triggered panic and the French king's surrender, at which his army fell apart and slaughter ensued.

Poitiers cost France its king, its constable and both marshals (their "pentagon"), one fighting archbishop, thirteen counts, five viscounts, 21 barons, and over 2000 knights & noble men-at-arms.

The English had so many prisoners (some archers 4,5, or 6 apiece), that they released many of them on the promise of paying their ransoms by Christmas. The French camp yielded huge amounts of plunder, including the king's jewel casket and a salt-cellar in the form of a silver ship.

Poitiers confirmed Crecy's verdict that armored knights no longer ruled the battlefield unchallenged. Possibly its greatest fallout was the shame of so many French fleeing without even fighting.

When the dauphin, the future Charles V approached the Estates General (France's version of Parliament) for money to ransom his father, they demanded government reforms. The Paris mob even forced him to wear a cap with the Paris colors, red and blue.

Neither War nor Peace (1360-69)

"Houses and churches no longer presented a smiling appearance with newly thatched roofs but rather the lamentable spectacle of scattered smoking ruins amid nettles and thistles springing up on every side. The pleasant sound of bells was heard indeed not as a summons to divine worship but as a warning of hostile intention, so that men might seek out hiding places while the enemy were still on the way. What more can I say?" --Prior Jean de Venette

The Treaty of Bretigny brought France no peace, because England failed to disband its mercenaries in England where they could raise all sorts of havoc. Rather, it turned these so-called *free companies* loose in France where they terrorized the people in what amounted to *chevauchees*, but ones with no strategic purpose or apparent leadership to restrain the worst sorts of atrocities. Although technically English, these companies attracted Germans, Gascons, Flemings, and even French to their ranks.

Typically, a company would seize a castle as a base from which to pillage surrounding towns and villages. One company made a living by capturing castles and selling them back to their owners.

To protect themselves, French peasants fortified their churches, slept on islands or boats in the middle of rivers, or dug tunnels into local hills and riverbanks. It was neither peace nor war, just some new kind of hell for the French people. Some even believed the English were demons, apparently thinking the knifemen's belts hanging from some of the mercenaries were tails.

Several leaders from humble backgrounds made their fame and fortune from these operations. One of them, Robert Knollys, commanded a company that plundered at will from Orleans to Vezelay and came to control forty castles. Locals reportedly would throw themselves in a river and drown at the mere word of his approach. Knollys was even knighted and handsomely rewarded for his service to the English crown. He later retired with the riches plundered from France and became known as a benefactor of churches and a founder of almshouses.

The free companies became especially dangerous when they combined into grand companies. The most renown of these was the White Company led by Nicholas Hawkwood, originally the humble son of a tanner. The White Company created tremendous havoc in

France, even capturing the pope at Avignon in 1361 and holding him for ransom.

Later, Hawkwood led the White Company into Italy where he had a renowned career as a condottiere (mercenary captain). Eventually, he retired married a daughter of the Visconti family, rulers of Milan, and retired with a pension of 3000 gold ducats from Florence.

Seeing no apparent difference between peace and war, the French resumed the war in 1369.

Agincourt (1415)

By 1413, the tide had turned back in favor of the English for a couple reasons. First of all, there was the rule of the mentally unstable French king, Charles VI, who suffered a malady that, among other things, made him believe he was made of glass and that he would shatter if anyone touched him. This unleashed factional strife over control of the king and policies between two noble houses: Orleans (who ruled when the king was sane) and Burgundy (who ruled when the king wasn't). This turmoil left France open to attack.

Meanwhile, England was recovering from a period of weak rule as the warlike Henry V took the throne and revived the English claim to the French throne. In 1415 he landed in France and laid siege to Harfleur in Normandy. Through the skillful use of artillery, he brought down the gate defenses and forced it to surrender in September. By now, it was too late in the year to march on Paris, so Henry embarked on a *chevauchee* just to let the French people know their king was there.

However, a French army probably triple the size of the English army was tracking Henry down. Over the next three weeks, the French kept

cutting off Henry's escape until he had to make a stand with his exhausted and sick army of some 1000 knights and 5-6,000 archers at Agincourt (10/26/1415).

The English were arranged in alternating formations of archers and knights, with archers on the wings in four ranks. They faced a French army of around 25,000 men drawn up in 3 lines with 500 mounted men on each flank (many of whom supposedly slept on their horses the night before to keep their armor from getting muddy).

The next morning, the English marched to within 300 yards of the French, a dangerous move if the overconfident French had been alert (which they weren't) and placed sharp stakes at chest level to the horses in a staggered pattern. They then opened fire in a high arc probably more to hit the French horses' rumps and send them rearing and plunging about. This plus the clatter of thousands of arrows clanging on armor prompted the angry French to charge, apparently unaware of the sharpened stakes, which were probably masked by English archers standing in front of them.

As the French cavalry came thundering down, knee to knee, at a full charge, the archers loosed one or two more volleys to bring down horses in front, tripping more behind them while others tried to rear back. But the momentum of the charging mass carried the rest of them forward.

At the last minute, the English dropped behind their stakes, causing a violent collision as horses were impaled, their riders thrown to the ground and pounced upon by the English. The surviving cavalry on the flanks veered off and retreated. The English unleashed several more volleys hitting the retreating horses sending them into a maddened and uncontrollable flight that crashed into the dismounted French knights coming up.

The collision sent a violent ripple through the crowd as men clutched at neighbors stumbling forward and backwards over them. Being so densely packed, they had no control over their movement and in many cases were lifted off the ground by the surging mass. Some men were knocked down into the mud and trampled to death in 60-70 pounds of armor.

Meanwhile, the English poured more arrows into their ranks, creating more disruption and more time for them to prepare for the next attack. As the French advanced, the English fired at a more deadly flat trajectory, pouring 5000 arrows a minute into the French ranks where casualties mounted, especially from wounds through visors and joints. As the French got closer, arrows even started piercing their plate armor.

Oddly, the French knights narrowed their attacks to the three groups of English knights, ignoring or avoiding the archers either from fear of arrows or because it was beneath their dignity to fight social inferiors. As a result, the French were squeezed into three narrow prongs, giving them little or no room to wield their weapons. In addition, the crush of men surging uncontrollably from behind pushed them helplessly toward the English who cut them down. The next men coming up stumbled over their fallen comrades, creating a tumbling effect as more and more bodies piled up.

Meanwhile, the French along the edges kept suffering from the volleys of arrows still being poured into their ranks. As the archers ran low on arrows and saw the enemy stalled and in confusion, they started attacking them in groups, one archer keeping a knight occupied from front while others got around behind, hit his knees, brought him down, and threatened to hammer a spike through his visor unless he surrendered.

However, many French asking for quarter were refused because the battle was hanging in the balance and the English couldn't spare men to guard prisoners.

The second wave of French coming up only aggravated an already awful situation.

Total time of battle up to now: 30 minutes

The second wave wasted much of its energy fighting those retreating and trying to slog through the mud in their heavy armor. One of them died of a heart attack as a result. The second wave did no better than the first.

The Field was now populated by the dead, wounded, and fugitives tracked by bounty hunters while prisoners were herded to the back in large groups without their right gauntlets and helmets.

However, the third wave, which outnumbered the now exhausted English, was still coming up. Therefore, in the face of the uncertainty of the final outcome, Henry ordered the prisoners massacred because he couldn't spare men to guard them. Some of the lower ranking mercenaries refused, not out of a sense of mercy, but because they wanted money from ransoms. Nevertheless, Henry found 200 archers who carried out the grisly task. In spite of this, the English still took 1000 prisoners.

Meanwhile, the third wave suffered the same fate as the first two, giving the English an incredible victory.

The next day, the English scoured the field, stripping the dead and finishing off the wounded, many of them mercy killings.

When Henry's sick and hungry army finally reached Calais, the townsmen charged such exorbitant prices for food, many soldiers lost their hard-won plunder as the price of a meal.

Thus the fortunes of war.

The Disasters of War (1413-29)

“There one might see wandering here and there children of two or three years old begging for bread as their parents were dead. These wretched people had only sodden soil under them and they lay there crying for food-- some starving to death, some unable to open their eyes & no longer breathing, others cowering on their knees as thin as twigs. A woman was there clutching her dead child to her breast to keep it warm, and a child was sucking on the breast of its dead mother. There one could easily count ten or twelve dead to one alive, who had died so quietly without call or cry as though they had died in their sleep.”- John Page on the siege of Rouen

After Agincourt, everything caved in on France.

For one thing, a civil war broke out between when the Duke of Orleans hacked the Duke of Burgundy to death while he was kneeling to the king on a bridge. Although the Orleans faction now dominated the French court, it was a bitter victory, because Burgundy now joined the English side (1419). Years later, a Carthusian monk showing Francis I the Duke of Burgundy’s skull, said *“This is the hole through which the English entered France.”*

While the French nobles indulged in civil war, Henry launched a serious campaign to conquer France, systematically reducing towns and castles, making especially good use of cannons. At the siege of Caen he placed cannons in tops of Abbey towers in a suburb to bombard town, firing stone shot and hollow iron balls filled w/flaming tallow that opened a breach in the walls. When an English knight fell in the moat during the assault, the French heaped flaming straw on him and burned him to death. When the enraged English took the town, they massacred 2000 inhabitants in revenge.

At the siege of Rouen, the desperate defenders, to save food, expelled 12,000 citizens, mostly women, children and the aged. However, since the English wouldn’t let them through, they starved and froze between the English and French lines. When the city finally surrendered and people brought food to the starving survivors, the shock of food after such long deprivation killed many of them. Of Rouen’s 15,000 people, only 6,000 survived.

As reports of English atrocities spread, people in other towns quickly surrendered or fled, such as Lisieux where only two cripples were left when the English arrived.

In 1420, England and France signed the Treaty of Troyes, sealing it with the marriage of Henry to Charles VI’s daughter, Catherine. It recognized Henry's claim to the throne after the deranged Charles VI should either die or shatter.

Despite this treaty, the war went on as Henry resumed his conquest of France, reducing one town after another.

The winter of 1420-21 was an especially harsh one for the French people. In efforts to escape the English, peasants flocked into the towns, thinking they would be safer. They weren’t.

Bodies of children were found in trash heaps where they died looking for food.

Wolves roamed Paris’ half deserted suburbs, picked up the scent of death, and left.

Then Charles VI died.

Unfortunately Henry had died one month earlier, leaving an infant as his successor.

So the war continued.

Luckily for England, the infant, Henry VI was well served by John, the Duke of Bedford, both an able administrator and general. Thus the next seven years were the most successful for the English...and the worst for France as the alliance of England and Burgundy unleashed a continuing avalanche of disasters upon the French.

In Normandy, freebooters, called flayers from the habit of flaying (skinning) their victims, reduced the land to a wilderness. And what the flayers didn't take or destroy, the English garrisons did.

Then, out of the most unlikely of places, came hope.

The Maid of Orleans (1429-31)

Joan of Arc enters Orleans after lifting the English siege.

In 1429, at the court of Charles, the dauphin (uncrowned king, since his way to Reims, where French coronations took place, was blocked) there arrived a humble peasant girl named Joan who claimed divine voices had told her to lead France to victory. The Dauphin, a very superstitious man, had the court theologians examine her and they found no sign of heresy or insanity. So, despite court snickering, Joan's persistence and genuine faith in her mission persuaded Charles to let her accompany a French force of 4,000 men to relieve the city of Orleans from an English siege. When the French stormed the enemy earthworks, the English raised the siege.

Whatever Joan's role in this victory, the French soldiers believed she was sent by God and successfully stormed several other English strongholds. These victories opened the road to Reims where Charles was officially crowned as Charles VII.

To the soldiers, Joan was a symbol of divine favor, and her example restored the army's spirit, especially after a seemingly miraculous recovery from a wound. However, her luck soon ran out. In 1429, the Burgundians captured Joan during an improperly supported attack on Paris and sold her to the English who tried her as a witch for hearing demonic voices that, among other things, spoke to her in French rather than English. After a long and exhausting trial, she was convicted by a French church court and burned at the stake in the market place of Rouen in 1431.

Years later the Church would reverse its decision and declare Joan a saint. She was only 19 years old when she died.

However, the English execution of Joan, much like the Church's execution of Jan Hus a few years earlier, backfired in the worst possible way.

It had created a martyr.

The Return of the King (1431-53)

Charles VII of France

Charles VII especially seems to have undergone some sort of transformation after Joan's death. He became a king in reality as well as name and led a vigorous offensive against the English. His leadership and hatred of the English convinced the French people to agree to a special tax, the *taille*, to pay for soldiers and artillery. This would be the primary form of tax income for the French monarchy until the French Revolution in 1789.

The 1430s saw fortune turn back against the English. There were crop failures and a severe depression in trade. In England, the weak Henry VI was unable to control the nobles who kept their own personal armies. In 1455, these armies would contribute to thirty years of civil war known as the Wars of the Roses.

The war in France was also going badly for England. At Chartres, French soldiers entered the city hidden in supply wagons and drove out the English.

Paris, still under English control, suffered from an especially harsh winter in 1435, bringing starvation and temperatures so cold that people were tearing down houses for firewood. In that year also the capable Duke of Bedford died with no leader of his caliber to replace him.

Less than a week later, Burgundy defected back to the French side.

The next year, 1436, the French retook Paris.

By the mid 1400s, more elaborate armor, mercenaries, and gunpowder were making warfare much more expensive than ever. Calais' garrison alone cost one-half of the English king's normal revenue. High war taxes and the lack of new plunder made the war increasingly unpopular in England. So did defeat as the French swept through France, demolishing English fortifications with their new artillery.

In the face of all these problems, Parliament cut most funds for fighting in France. The end wasn't far off.

It came in 1451 at the Battle of Castillon. The French, using another experimental weapon, primitive firearms, defeated the last English army in France. Two years later in 1453, the same year the Ottoman Turks used artillery to help them storm the walls of Constantinople, the English were out of France except for the port of Calais, which they managed to hang onto until 1558.

The Hundred Years War was over.

11.1 THE PRINTING PRESS & ITS IMPACT

Introduction. At the height of the Hussite crisis in the early 1400's, when authorities ordered 200 manuscripts of heretical writings burned, people on both sides realized quite well the significance of such an act. Two hundred handwritten manuscripts would be hard to replace. Not only would it be a time consuming job, but also trained scribes would be hard to find. After all, most of them worked for the Church, and it seemed unlikely that the Church would loan out its scribes to copy the works of heretics. Although the Hussites more than held their own militarily against the Church's crusades against them, their movement remained confined mainly to the borders of their homeland Bohemia. This was because there was no mass media, such as the printing press to spread the word. A century later, all that had changed.

The Problems with Hand-written Books. Hand-written books were prone to mistakes from a variety of sources. One of these was the system used for copying books. Since university students couldn't generally afford their own copies of textbooks, they would rent 8-page sections, known as *peciae*, from a book dealer. To get their own or more copies, richer students and book dealers would hire poorer students to copy the *peciae* for them.

Such students were often inadequately literate to understand the texts they were copying, especially since they were written in Latin. Poor handwriting (of either the scribe copying the older text, the scribe making the new copy, or both) compounded the difficulty (and legibility) of the task. So did the condition of

the text, which may have gone through many less-than-careful sets of hands between being literally chewed up by bookworms. (Surviving copies of medieval manuscripts often have such bookworm holes going all the way through them.)

Yes, there are such things as bookworms. However, instead of there being a single species of bookworm, per se, a number of insects, such as silverfish, booklice, and even termites and roaches, that feed on the starchy material in the pages of a book collectively fall under this category.

Other factors contributing to the mess would be the poor lighting produced by oil lamps, the boredom and fatigue of mindlessly copying page after page of oftentimes incomprehensible and illegible text. Thus, a scribe might doze off while copying a common Latin word, such as *idem*, on line seven of a page, wake up and pick up at *idem* on line eleven, thus eliminating four lines of text. Boredom, fatigue, and poor pay could also generate anger and resentment in a copier, who might write jokes or nasty comments about the book dealer in the margins.

Because they were only paid for eight pages of copying, scribes would often cram in the last few lines of a page along with using tons of abbreviations to avoid the cost of using more paper or parchment. In addition, different scribes typically copied different *peciae* of each copy of a book, complicating efforts to sort out who had copied what specific mistakes and where they had originated. Of course, later copiers would mindlessly incorporate all of these mistakes and imperfections into their copies, along with a few of their own. And so it would go through the generations, one set of mistakes being piled on top of another along with generations or centuries of abuse, until later generations of scholars tried to sort out the mess.

Like any other invention, the printing press came along and had an impact when the right conditions existed at the right time and place. In this case, that was Europe in the mid 1400's. Like many or most inventions, the printing press was not the result of

just one man's ingenious insight into all the problems involved in creating the printing press. Rather, printing was a combination of several different inventions and innovations: block printing, rag paper, oil based ink, interchangeable metal type, and the squeeze press.

Much of this started with the rise of towns in Western Europe that sparked trade with the outside world all the way to China. That trade exposed Europeans to three things critical to the invention of the printing press: rag paper, block printing, and, oddly enough, the Black Death.

For centuries the Chinese had been making rag paper from a pulp consisting of water and discarded rags that was then pressed into sheets of paper. When the Arabs met the Chinese at the battle of the Talas River in 751 C.E., they carried off several prisoners skilled in making such paper. The technology spread gradually across the Muslim world, up through Spain and into Western Europe by the late 1200's. The squeeze press used in pressing the pulp into sheets of paper would also lend itself to pressing print evenly onto paper.

Chinese paper was made from bamboo stalks that were stripped of leaves of smaller branches, and then boiled in a tub for three days to break them down into thin hair-like fibers. The mixture, known as a slurry, was cooled in a large brick tub where a specialist dipped a silk screen, then extracted it, letting most of the water drain through the silk, leaving a thin layer of slurry. The screens were stacked and allowed to partially dry, after which the slurry, having coalesced into sheets of paper, was dumped from the screens onto a stack of similar sheets. After drying some more, the sheets were hung outside to completely dry, after which they were full sheets of paper.

Chinese movable type. A Chinese inventor, Bi Sheng, actually came up with movable type in the 1040s, carving Chinese characters into uniformly sized clay blocks that were then fired. He then arranged them in vertical rows inside a rectangular frame, inked them with a mixture of gum and soot made from burned pine, and pressed a piece of paper over them to get a printed page.

The problem was that storing and cataloging a writing system of literally thousands of characters was extremely tedious and impractical. Therefore, the Chinese reverted to the simpler technique of carving entire pages of text out of wood, a system devised back in the eighth century. Supposedly, there were 500,000 copies of one Buddhist text printed with this technique.

The Black Death, which also spread to Western Europe thanks to expanded trade routes, greatly catalyzed the invention of the printing press in three ways, two of which combined with the invention of rag paper to provide Europe with plentiful paper. First of all, the survivors of the Black Death inherited the property of those who did not survive, so that even peasants found themselves a good deal richer. Since the textile industry was the most developed industry in Western Europe at that time, it should come as no surprise that people spent their money largely on new clothes. However, clothes wear out, leaving rags. Consequently, fourteenth century Europe had plenty of rags to make into rag paper, which was much cheaper than the parchment (sheepskin) and vellum (calfskin) used to make books until then. Even by 1300, paper was only one-sixth the cost of parchment, and its relative cost continued to fall. Considering it took 170 calfskins or 300 sheepskins to make one copy of the *Bible*, we can see what a bargain paper was.

However, the Black Death had also killed off many of the monks who copied the books, since the crowded conditions in the monasteries had contributed to an unusually high mortality rate. One result of this was that the cost of copying books rose drastically while the cost of paper was dropping. Many people considered this unacceptable and looked for a better way to copy books. Thus the Black Death rag paper combined to create both lots of cheap paper plus an incentive for the invention of the printing press.

The Black Death also helped lead to the decline of the Church, the rise of a money economy, and subsequently the Italian Renaissance with its secular ideas and emphasis on painting. It was artists in Northern Europe who, in their search for a more durable paint, came up with oil-based paints. It was

fairly simple to adapt these to an oil-based ink that would adhere to metal type.

Block printing, carved on porcelain, had existed for centuries before making its way to Europe. Some experiments with interchangeable copper type had even been carried on in Korea. However, Chinese printing did not advance beyond that, possibly because the Chinese writing system used thousands of characters and was too unmanageable. For centuries after its introduction into Europe, block printing still found little use, since wooden printing blocks wore out quickly when compared to the time it took to carve them. As a result of the time and expense involved in making block prints, a few playing cards and pages of books were printed this way, but little else.

What people needed was a movable type made of metal. And here again, the revival of towns and trade played a major role, since it stimulated a mining boom, especially in Germany, along with better techniques for working metals, including soft metals such as gold and copper. It was a goldsmith from Mainz, Germany, Johannes Gutenberg, who created a durable and interchangeable metal type that allowed him to print many different pages, using the same letters over and over again in different combinations. More importantly, Gutenberg combined all these disparate elements of movable type, rag paper, the squeeze press, and oil based inks to invent the first printing press in 1451.

The first printed books were religious in nature, as were most medieval books. They also imitated (handwritten) manuscript form so that people would accept this new revolutionary way of copying books. The printing press soon changed the forms and uses of books quite radically. Books stopped imitating manuscript forms such as lined paper to help the copiers and abbreviations to save time and space in copying. They also covered an increasingly wider variety of non-religious topics (such as grammars, etiquette, and geology books) that appealed especially to the professional members of the middle class.

The problems and process of early printing. The real trick to creating a working printing press was making metal type that was of uniform thickness so that all the letters would press down on the paper. What made Gutenberg

especially suited for this was his trade as a goldsmith, because he was skilled in working with soft metals, in particular copper, that were more durable than wooden type but easier to work with than harder metals like iron.

Printing wasn't yet the lightning fast process we have today. For each page, the type had to be inked, the paper had to be individually laid down, and the printer had to use a good deal of strength in pulling back the bar to press the inked type to the paper. After removing the page and hanging it up to dry, he would start all over.

It was still a lot better than having to hand copy each page.

One way to shorten the process was the *folio*, which involved printing two pages at once on a double sized sheet. Later, two more pages would be printed simultaneously on the backside of the sheet. Of course, this involved a lot of prior planning, because in assembling the folded sheets into a book, two consecutive pages would rarely be printed side by side. For example, an 8-page folio would have pages 1 and 8 printed side by side and backed by 2 and 7. Similarly, pages 3 and 6 would be printed together and backed by 4 and 5.

Assuming pages are numbered sequentially from the very first to the very last page, the sum of any two pages printed together within a book always adds up to the same number as the sum of any other two pages. Back when books were still assembled by hand, this could be a valuable check on the correct pairings of pages for each folio sheet.

Behind the printing press were trays of interchangeable type for setting up new pages. The need to organize the letters in a way for efficiently finding them led to standard alphabetization.

Printing was such a revolutionary way to copy books that when Jacob Fust, Gutenberg's

partner, started selling Bibles in Paris, local book copiers, acutely aware that printed books could put them out of business, wanted Fust arrested for conspiring with the Devil to be able to make so many identical copies so quickly. Of course, this begs the question of why the Devil would help make so many copies of the word of God. Fust got off the hook.

Aldus Manutius invented italics, supposedly based on the handwriting of the medieval Italian scholar, Petrarch. The wide variety of fonts we have today got started by early printers who adopted the most fashionable handwriting style for their type. One font had no fewer than 240 characters.

By 1482, there were about 100 printing presses in Western Europe: 50 in Italy, 30 in Germany, 9 in France, 8 each in Spain and Holland, and 4 in England. A Venetian printer, Aldus Manutius, realized that the main market was not for big heavy volumes of the Bible, but for smaller, cheaper, and easier to handle "pocket books". Manutius further revolutionized book copying by his focusing on these smaller editions that more people could afford. He printed translations of the Greek classics and thus helped spread knowledge in general, and the Renaissance in particular, across Europe. By 1500, there were some 40,000 different editions with over 6,000,000 copies in print, compared to an estimated total of only 30,000 copies in 1400.

Printing images and in color. Maybe as important as the revolution in printed words was the revolution in printed images made possible by engraved woodblock images. This became especially apparent in 1536 with the publication of Vesalius' *De Fabrica*, which contained the first truly accurate drawings of human anatomy, making it possible for medical students everywhere in Europe to view how the human body really looked and functioned, thus pushing medical knowledge still further.

Not that the literal truth was the only thing being printed. The printing press also proved useful for religious and political propaganda. The first major example of this was the Protestant Reformation, when Protestants in

particular printed scathing cartoons of the pope and Catholic Church. Such images were even more powerful and persuasive when done in color.

Color printing was done with separate copper plates, one for each color being used, the different color plates applied one after the other to create the full color image. The trick was tightly calibrating the two plates so the colors stayed separate.

The impact of the printing press. The printing press had dramatic effects on European civilization. Its immediate effect was that it spread information *quickly* and *accurately*. This helped create a wider literate reading public. However, its importance lay not just in how it spread information and opinions, but also in what sorts of information and opinions it was spreading. There were two main directions printing took, both of which were probably totally unforeseen by its creators.

First of all, more and more books of a secular nature were printed, with especially profound results in science. Scientists working on the same problem in different parts of Europe especially benefited, since they could print the results of their work and share it accurately with a large number of other scientists. They in turn could take that accurate, not miscopied, information, work with it and advance knowledge and understanding further. Of course, they could accurately share their information with many others and the process would continue. By the 1600's, this process would lead to the Scientific Revolution of the Enlightenment, which would radically alter how Europeans viewed the world and universe.

The printing press also created its share of trouble as far as some people were concerned, since it took book copying out of the hands of the Church, thus making it much harder for the Church to control or censor what was being written. It was hard enough to control what Wycliffe and Hus wrote with just a

few hundred copies of their works in circulation. Imagine the problems the Church had when literally thousands of such works could be produced at a fraction of the cost. Each new printing press was just another hole in the dyke to be plugged up, and the Church had only so many fingers with which to do the job. It is no accident that the breakup of Europe's religious unity during the Protestant Reformation corresponded with the spread of printing. The difference between Martin Luther's successful Reformation and the Hussites' much more limited success was that Luther was armed with the printing press and knew how to use it with devastating effect.

Some people would go as far as to say that the printing press is the most important invention between the development of writing and the computer. Although it is impossible to justify that statement to everyone's satisfaction, one can safely say that the printing press has been one of the most powerful inventions of the modern era. It has advanced and spread knowledge and molded public opinion in a way that nothing before the advent of television and radio in the twentieth century could rival. If it were not able to, then freedom of the press would not be such a jealously guarded liberty as it is today.

Random Facts About Early Printing

The medieval mind rejected alphabetic order as irrational. Thus there was no indexing of topics within books or of books within libraries. Not until the printing press was there regular use of punctuation, spacing, paragraphs and capital letters and efforts to create uniform spelling. William Caxton's choice of dialect and the large number of books he published helped lead to a more standardized English.

Because the early printed page was arranged as a composition and work of art, typesetters were known as compositors.

Since people typically conceive of a new technology within the limitations of the old technology, early printed books still used lined paper and a multitude of abbreviations even though space, time of copying, and neat rows of writing were no longer an issue. For example, *nris*, the old abbreviation for the Latin word

***nostris*, is still being used in the printed text below**

Ancient and medieval dialogues between two points of view were a popular form for printed books for years.

Dedications originally were to patrons or hopeful patrons.

The idea of copyrighting authors' works began in the 1400s.

Cloth binding for books was invented in the early 1800s.

The term "lecturer" comes from the Latin word for reader, since teachers often read the one available book aloud to his students. Similarly, because of the scarcity of books before the printing press, reading was largely a social activity where one person read aloud to others. Not until printing and the wide availability of books did reading become a silent and solitary exercise, just one of a number of inventions that have made for much less social activity in the modern world.

The book has weakened individual and collective memories and divided the intellectual world into specialized niches without one center of knowledge. Before the profusion of printed books and corresponding explosion of knowledge, the traditional concept of a scholar was someone who had read all the known classical literature.

75. THE ECONOMIC RECOVERY OF EUROPE (c.1450-1500)

The turmoil of the Later Middle Ages (c.1300-1450) continued and accelerated the changes that started with the rise of towns and kings in the High Middle Ages (c.1100-1300). Although these were certainly difficult times to live through, they also paved the way for the modern institutions, movements, and values that would emerge after 1450: the Renaissance with its new attitudes toward the secular world and Man's place in it, the nation state with its relatively centralized bureaucracy and army, and the age of exploration with the new perspective it gave on Europe's place in the world, and capitalism with its new attitudes toward money and profit.

Social changes. The turmoil of the Later Middle Ages did not affect everyone equally. Nobles and clergy, in particular, saw their power decline. The longbow, gunpowder, and massed formations of infantry pikemen effectively challenged the armored knight's supremacy on the battlefield. Even his place in the castle grew ever more precarious as new and more destructive cannons were constantly being developed. Similarly, religious scandals, corruption, and heresies had hurt the Church's reputation and influence. Economically, the Later Middle Ages had seen labor shortages that led to higher prices. Inflation cut increasingly into the wealth of the nobles and clergy, since it was based on land with a more static value. By 1450, most peasants in Western Europe had been able to buy freedom from their lords, wither sharecropping or paying them fixed rents instead of labor. Even those rents only helped in the short run, since inflation soon reduced their value, while the nobles and clergy often had little skill or desire to spend within their means.

The nobles' decline meant other social classes could rise in power and status. Peasants benefited by buying their freedom and many even buying their own land. The greater incentive provided by working for themselves rather than their lords generated higher rates of agricultural production and the revival of Europe's population. The middle class benefited by making money from selling them

goods to the nobles for a profit and even giving them loans for interest so they could buy those goods. The middle class was also assuming larger roles as bureaucrats and bankers for the emerging national monarchies in Western Europe. Thanks largely to the natural alliance of kings and middle class against the nobles, kings were the only ones with the power and wealth to afford the new gunpowder technology that was becoming a necessary part of any respectable army.

Although there were still some powerful and influential nobles, others were forced to seek employment in the king's army or at his court as *courtiers*, basically idle hangers-on whose job was to make the king's court look impressive. Still others lost their noble status altogether by having to support themselves through such *ignoble* pursuits as agriculture and commerce. Nonetheless, nobles were still considered *the* class to be. Consequently, wealthy members of the middle class would buy titles of nobility from the king (who always needed cash), give up their businesses, and settle down on landed estates just like other nobles. In this way, the nobles' ranks were constantly replenished by new blood, although their importance as a class kept on its path of gradual decline. The changes sweeping through Europe were making it increasingly harder to find a meaningful place in society for themselves.

Thus, by 1500, the peasants in Western Europe free and often in possession of their own land, the middle class' status was steadily rising, both through their money and positions in royal bureaucracies, and kings were tightening their grips on power through their bureaucracies and armies.

Economic revival, as usual, was based firmly on agriculture revival, but other factors also helped. For one thing, the turmoil of the Later Middle Ages, which had weakened the Church and Nobles, was largely subsiding in Western Europe by 1450. Out of this emerged strong monarchies that could safeguard the peace and promote trade and commerce. Secondly, the nobles, ruined by inflation and the collapsed urban grain market triggered by the Black Death, had sold most of their serfs their freedom by 1450. Finally, the peasants who had survived the Black Death and inherited the

property of those who died had attained a higher standard of living. The fact that most peasants were now free and that many owned their land provided incentive to work harder that led to better agricultural production. One good indication that this was taking place was the fact that Europe's population rose from an estimated 50 million in 1450 to 70 million by 1500. This revival had three effects that would combine to create a dynamic new economic system: capitalism.

First of all, the dramatic population growth of the late 1400's meant that towns and trade could also rapidly recover and surpass their previous prosperity. In 1450, the wealthiest banking family in Europe was that of the Medici of Florence, whose fortune consisted of 90,000 florins. By the 1500's, another banking family, the Fuggers of Augsburg in Germany, had taken over first place with nearly one million florins to their credit, over ten times that of the Medici half a century before. What this suggests is that the amount of trade and money in circulation had increased a great deal.

The second effect was that there were new consumer markets, but with a very different distribution of wealth from before. In the High Middle Ages, nobles had provided merchants with much of their market since they controlled so much of Europe's wealth at that time. By 1450, this had changed. Most nobles had lost money and status and could not afford the fine woolens and other goods made by the guilds. Instead there were common laborers and peasants, each with a modest amount of money to spend. A lot of money was there. It was just spread out more widely.

This change in the consumer market from a few rich nobles to a large number of people each with modest amounts of cash led to a change in production techniques as well. Up to this point, guilds had controlled the production and selling of manufactured goods, while nobles could afford the high quality and prices that the guilds maintained. The new type of consumer emerging by 1500 could not afford them. In response to this, some wealthy businessmen went outside the town walls and the jurisdiction of the guilds to the various peasant cottages in the countryside. Here the peasants would produce lower quality woolens than the

guilds produced. The businessmen would pay them lower prices for those woolens and turn around and undersell their guild competitors. In this way, older medieval cities and guilds, such as in Flanders, went into decline, while other centers of production took their places. This also led to the growing concentration of wealth in the hands of a few rich businessmen instead of being spread out among the guilds. Thus by 1500, the consumer market was more spread out than before, while the means of production and investment were concentrated in fewer hands.

The third effect of Europe's reviving economy was that its expanding internal markets prompted Spanish and Portuguese explorers to search for new trade routes to the sources of spices in the Far East. Besides opening up whole new continents for discovery and exploration, this also vastly expanded the volume of Europe's trade.

Economics as a Secular Act of Faith

On the surface, trading something of inherent value (such as food or clothes) for something as pretty, but inherently useless, as gold or silver seems pretty crazy. And trading a piece of paper saying it's worth gold or silver seems crazier still. Of course, money and credit vastly facilitated and expanded trade and are essential parts of our economic system.

However, we should never lose sight of the fact that our whole economic system relies largely on one ephemeral but critical element: faith. As long as people believe the economy is working, they will spend money on new TV's and invest in new businesses and the stock market. And as long as people keep buying and investing, factories will keep producing new products, thus hiring workers who get paychecks and, feeling good about their jobs and the economy, will keep buying TV's, etc., etc.

But if people stop believing, the whole process goes into reverse.

It's all about faith, not just by one person, but whole societies. So, to a large extent, our whole civilization is based on a form of mass insanity.

New business techniques. In order to handle this higher volume of trade, new techniques of handling money became prevalent about this time. The Italian city-states especially pioneered these new methods. The prosperity that these new business techniques brought Italy largely explains why Italy would lead the rest of Europe in the Renaissance. Very briefly, these techniques were:

1) *Joint stock companies.* These allowed people with small amounts of cash to take part in business enterprises such as merchant expeditions. Their importance was that, instead of hoarding their money, people put it into circulation in Europe's economy, allowing it to grow even more.

2) Insurance companies. These reduced the risk of losing all of one's investment in a business venture. The result was much like that of joint stock companies, in that it encouraged people to invest, rather than hoard, their money, which stimulated further growth in Europe's economy.

3) Deposit banks and credit. Credit allowed a businessman to use more money than he actually had to embark on some venture, paying his creditor back with interest when he made his profit. Europe's economy grew much more quickly this way than if it had been limited by the amount of cash on hand at any particular time. Unfortunately, with a strictly cash economy, someone transferring funds long distance ran the risk of losing his money to brigands, pirates, or storms.

Luckily, there were two parties with complementary needs that led to a solution. One was the Church, which needed to send its taxes to Italy from all over Europe. The other consisted of Italian merchants, especially Florentines, who wanted to take money from Italy to destinations across Europe in order to carry on trade. With credit, the same merchant could send an agent to London with a note saying he was worth so much money guaranteed by the bank back in Florence. The agent could get that money in the form of church taxes bound for Italy, use it in England, and then send a credit note back

to Florence worth the amount he borrowed in Church taxes. If brigands ambushed an agent either way, all they got was a credit note that they could not spend. Meanwhile, the Florentine banker got hold of all the funds he needed in England, and the Church in Italy safely collected its taxes from England...all without transferring one bit of cash.

As this practice caught on, there were other people who wanted to transfer funds across Europe without the risks that came from traveling with cash. Therefore, they would deposit cash with a merchant who had branch offices all over Europe, take a letter of credit to their destination, and reclaim their cash from the merchant's branch office there. Naturally, the merchant would charge a fee for this service. He would also use the money deposited with him for his own business deals, hopefully making a profit on the depositor's cash before he reclaimed his money. Thus was born our modern institution of banking, an essential ingredient in the capitalist system.

There were dangers to this system, especially debtors not repaying their creditors. Kings were especially bad risks in this respect. For example, in the 1340's, Edward III of England failed to repay the Bardi and Peruzzi firms of Florence. This caused their bankruptcies, which sent ripples throughout Western Europe's economy since so much of it was tied up with these two banking houses.

These new business techniques combined to create a feedback cycle that accelerated the growth of Europe's economy. More money was invested in new business ventures. This increased trade, which stimulated more production of goods. That, in turn, created more jobs for people, who had more money to spend, which was safer because of the new business techniques, and so on.

Overall, the system worked quite well, providing money for the expansion of Europe's economy and the growth of its monarchies. Two other important factors should be mentioned. One is the dramatic improvement in mining techniques in Europe at this time. Germany in particular saw a fivefold increase in mining production between 1400 and the early 1500's, which put much more silver into circulation.

Secondly, the adoption of Arabic numerals improved accounting techniques so trade and business could run more efficiently. All this increased economic activity and prosperity transformed European values and attitudes toward money and helped create a new economic system called capitalism.

Florins and Ducats

Two gold coins, the Venetian ducat (left), which maintained a purity of 99.9% for 500 years, and the Florentine florin, especially symbolized the increasingly money based economy. While Roger II of Sicily started minting coins called ducats around 1140, the first regular issue of gold coins was by Florence in 1252, followed in 1284 by Venice. Because of their stability, large-scale monetary deals and sums were often expressed in terms of one or other of these coins.

Capitalism is an economic activity that involves using large sums of money or **capital** in large-scale commercial, manufacturing, or agricultural activities. It had some medieval roots, but also some non-medieval elements that did not develop until around 1500. We can isolate four main characteristics of capitalism:

1) Private ownership of the means of production.

This was largely a break from the Middle Ages when guilds controlled the means of production. We have seen how wealthy businessmen started to break the guilds' monopoly by having peasants produce textiles in the countryside. This process continued and accelerated after 1500. Modern communism theoretically has the means of production owned by the workers, represented by the government, which in some ways seems closer to medieval guilds than its main rival, capitalism.

2) The law of supply and demand determines prices.

Once again, this is a break from the guilds which kept prices artificially fixed no matter how plentiful or scarce its goods were. Communist governments also control prices in a similar way.

3) There is a sharp distinction and often little contact between the workers and the capitalist who owns the means of production. Such a distinction existed to a much smaller degree between guild masters and their laborers, and this became a serious problem in the later Middle Ages. Such a gap between capitalists and their workers would widen considerably and become especially bad in the early Industrial Revolution of the 1800's.

4) The profit motive. Although medieval guilds and merchants made profits, those profits were largely restricted by the Church's ban against charging more than a "fair price" for goods and services. The emergence of the profit motive by 1500 especially shows the changing attitudes and values in European civilization.

Capitalism helped lay the foundations for the rise of national monarchies in Europe by providing them with the capital to build up strong professional armies and bureaucracies. The states that best adapted to capitalism, in particular the Dutch Republic in the 1600's and England in the 1700's, would emerge as the economic and political powerhouses of Europe and eventually establish dominance of the world in later centuries. European prosperity in the later 1400's also made patronage of the arts possible and helped create one history's greatest cultural movements: the Renaissance.

Money, Women, and literacy

Although during the Middle Ages, most of the few books being written and copied were of a religious nature, the rise of towns and trade after 1000 C.E. led to a new literate class of merchants with different uses for literacy, namely keeping accounts and writing business contracts. They also might have other reading interests outside of religious topics, although that didn't matter much as long as Churchmen were the main group copying books. However, with the printing press printers quickly saw the potential

for exploiting this new reading market, and started printing books on more secular topics.

Interestingly enough, it wasn't just a male market either, because the wives of merchants and guild masters had a somewhat higher status, especially in Northern Europe where they actively helped in their husbands' business. In England, a guild master's widow could even run his business if she had no sons or until her sons were old enough to take over on their own.

Consequently, women involved in helping with the family business would know how to read as well. Two paintings in the 1500s, one by Quentin Metsys and the other by Marinus Claesron van Reymerwarle, tell us this in their portrayals of merchants and their wives counting their profits. Even more telling, the woman in each painting has her fingers on an open book, symbolizing she can read. While literacy rates for men would remain far higher for men than women for centuries, the gap was starting to close.

Continuing feudal burdens

To say that the peasants had bought their freedom needs to be qualified, because a myriad of feudal dues and obligations remained to provide some income to the nobles and misery to the peasants. For example, peasants were often still obligated to use the lord's mill, paying, on average, one bag of flour for every twenty that was milled. Similarly, they might have to pay to use his oven, roads, and bridges. Then there was the corvee, several weeks of forced labor in the summer to repair the lords' bridges and roads.

Maybe the most hated of the nobles' feudal rights was the captaineries, which gave them hunting rights on the peasants' lands. Besides trampling the crops in pursuit of game, this might even involve delaying the time of planting or harvest because partridges needed ground cover for nesting and laying their eggs. One noble, the Prince de Conde, even raised wolves and turned them loose on the peasants' lands for his hunting enjoyment. Any peasants or their children lost during these festivities should have been paying closer attention.

These feudal burdens would remain in France all the way to the night of August 4, 1789 during the French Revolution when the National Assembly would finally abolish all vestiges of feudalism.

The Would-Be Gentleman

Or A Quick and Dirty Guide to Social Climbing in Early Modern Europe

Qualifications for nobility were different from one country to the next. For example, in England, it was purely through heredity, so there was a fairly small class of nobles (known as the peers or peerage) compared to France. However, there was no specific legal status or class known as the gentry, who have popularly been seen as the lower nobility.

In France, there were three ways to become a noble:

- 1) Inheriting the status from your father if he had permanent noble status;
- 2) By a special letter from the king; or
- 3) Buying the status.

By the 1700s, there were 4,000 offices one could buy that conferred nobility. To buy noble status, one must buy an office that conferred nobility. Some offices (e.g., judges in the Paris Parlement and the hundreds of "royal secretaries") immediately conferred permanent nobility on the first generation holding that office. Others (e.g., mayors and tax collectors) typically did not receive permanent status only after the third generation of a family holding that office

Keep in mind that buying an office (and noble status) was like buying a car or house today. It was the personal property of the person who bought it and could be handed down to succeeding generations. By the same token, one could sell an office, thus depriving one's descendants of that office and noble status, unless he sold it after attaining permanent noble status, which he could then hand down to his heirs without the office being attached.

Military offices were one category of positions that commoners could not buy. While this kept a lot of rich people with no military talent from infecting the army with their incompetence, it also kept out a lot of potential new talent, often to France's detriment in its many wars all the way down to its revolution in 1789.

Noble status was just the first step in social climbing among the elite. There were four main factors determining your position within the noble hierarchy:

- how long your family been noble, three generations being a major threshold;
- what other families you had married into;
- what offices and titles you and your family members had achieved; and
- what notable actions they had performed

One critical step was finding a suitable marriage into a family with power, prestige, and wealth, especially the latter, because an aspiring noble needed a sizable dowry to climb the ladder of success. However, a suitor had to be careful not to set his sights too high, because trying to win a bride from an extremely prestigious and powerful family would likely meet with rejection and damage his still fragile status

Having children was another important decision for building a powerful family. Having too many sons could dissipate a noble's wealth, but having no sons to succeed him would be the end of the line. Of course, the fly in the ointment was the high rate of infant and child mortality, probably 50% by age twenty. But child mortality varied widely from family to family, so one never knew how many, if any, children would survive him. If a noble were blessed with several healthy sons, he could limit the size of his family by finding "romance" with a mistress or various peasant girls. (However, his wife didn't have such options, since any children born would be of suspect legitimacy.) If a noble's legitimate sons all died, he could have any bastard sons declared legitimate noble heirs by a letter from the king.

Money was important to a noble, not as goal in itself, but as a means to social prestige. Thus an

ambitious noble needed to make astute investments within the legal restrictions of his class. Practicing certain ignoble occupations, such as commerce or manual crafts, would cost one his noble status. Other trades, such as medicine, glass blowing, exploitation on mines and maritime and wholesale commerce were tolerated. So was tilling the soil, as long as it was the noble's own land and not someone else's.

Three types of investments were in tax farms, textiles (wholesale) and land. Tax farms were the most lucrative, but also disreputable, so a noble involved in that might lose status in the eyes of his peers. Textiles were also lucrative, but also riskier, while land was the safest long-term investment.

A noble with land also had two main options on how to manage it. He could collect fixed monetary rents, which were stable, but also more subject to inflation. Or he could let his peasants sharecrop and take a percentage of the grain as rent. He could then either sell the grain in town or store it and wait for a year when grain production was down and then sell it for a greater profit. One danger here, however, was that rats and spoilage would reduce his grain stores each year.

An aspiring noble also wanted to get a title, such as duke or count. In the middle ages, these were titles held by noble families that had fought their way up in society as members of the warrior class and established as much power and independence from the king as they could. However, over the centuries, the monarchy had gradually regained control of these titles through such things as marriage and the extinction of family lines, whereby the titles reverted to the king by a custom known as escheat. By 1600, the king controlled these titles and could grant them at will to those gaining his favor. The hierarchy of titles was:

- 1) Duc (duke)
- 2) Marquis (marquis)
- 3) Comte (earl)
- 4) Viscomte (viscount)
- 5) Baron (baron)

Of course, a lowly first generation noble couldn't expect to get a title on his own. He needed help from a patron, so he would vie for the patronage of a powerful noble who could work in higher circles of power for his benefit and protect him from enemies who would try to subject him to fines, confiscations, and the humiliation of scandal. Thus a lower noble's fortunes were tied to those of his patron, and if that patron fell from favor, so did his clients.

And no self-respecting noble is going to be taken seriously if he doesn't have his own castle in the country, or what we now refer to as a chateaux. Many or most castles fell into disrepair, but a number of them, in particular along the Loire River close to Paris, were renovated as country estates. Except now they were built more for comfort, and less for defensive purposes.

Nobles of the sword and the robe

Naturally, the older noble families showed disdain for any upstarts who had bought noble titles. Therefore, they drew a sharp distinction between themselves and the newcomers. Older noble families referred to themselves as nobles of the sword, implying their noble titles went back to when nobles actually did most of the fighting. Newer noble families who had just bought their titles and offices (such as Charles Alexandre de Calonne pictured above by Elizabeth Vigee Le Brun) were called the nobles of the robe, a reference to the bureaucratic or judicial robes they might wear as holders of their new offices. However, after three or four generations, these nobles were no longer newcomers compared to all the other nobles who had bought their titles more recently. Therefore, they could consider themselves members of the old nobility and now refer to themselves as nobles of the sword, even if they didn't know one end of a sword from the other (although they would learn pretty quickly if caught in a duel).

The Truth Behind Fairy Tales

Fairy tales, or more properly folk tales, give us one of the few insights into how common people felt about medieval society. Take, for instance, the villains, who typically are evil ministers or women, often with diabolical magical powers

that allow them to control events. Since the king's ministers and advisors typically came from the noble classes, their portrayal as evil largely reflects the commoners' views of nobles as the enemy and source of their troubles.

Women also feature prominently among villains, because of the belief that it was an inversion of the natural order for women to be in power. Therefore, such women must be evil. This also means that real women in power, such as Marie de Medici and Marie Antoinette of France, were typically seen as evil and scheming (maybe even witches) and had a hard time getting fair treatment from historians of the time (almost all of them men). Only recently have historians been reassessing these women's lives and giving them more balanced treatment.

By contrast, kings are seen as good, because they were the natural allies and protectors of peasants and townsmen against their common enemy: the nobles. Therefore, if things are going badly in the kingdom, it's not because the kings are bad, but because they are under the influence (or spell) of evil ministers or queens. Once the spell is broken, the king or his son the prince (AKA Prince Charming) can again rule and bring the kingdom prosperity.

THE BIRTH OF BANKING

The word *bank* comes from the Italian word *banco* referring to the bench or counter at markets and fairs where moneylenders did their business. If they lost all their money and went out of business, officials would literally break the *banco* with an ax, signifying they were *bankrupt*.

One of history's most important financial innovations was banking, which was closely bound up with credit. The main problem spurring on this development was the need to safely transport large amounts of cash over long distances in order to carry on trade across Europe. Such journeys were particularly beset by two dangers: natural disasters, especially storms, and attacks by pirates or brigands. Luckily, there were two parties with complementary needs that led to a solution. One was the Church, which needed to send its taxes to Italy from all over Europe. The other consisted of Italian merchants who wanted to take money from Italy to destinations across Europe in order to carry on trade.

At some point, a merchant started sending agents to other countries to trade. However, instead of carrying cash, they had letters of credit that they would present to local Church officials in return for cash that they could use there for trading. When they or church officials returned to Italy, they would bring letters of credit worth the amount borrowed from the Church and present them to the Italian merchant who would then give the church the money he owed them. In that way, both parties could transfer large amounts of money across Europe without carrying any cash.

As this practice caught on, there were other people who wanted to transfer funds across Europe without the risks that came from traveling with cash. Therefore, they would deposit cash with a merchant who had branch offices all over Europe, take a letter

of credit to their destination, and reclaim their cash from the merchant's branch office there. Naturally, the merchant would charge a fee for this service. He would also use the money deposited with him for his own business deals, hopefully making a profit on the depositor's cash before he reclaimed his money. Thus was born our modern institution of banking, an essential ingredient in the capitalist system.

THE ITALIAN RENAISSANCE (1400-1600)

*"...everything that surrounds us is our own work, the work of man: all dwellings, all castles, all cities, all the edifices throughout the whole world, which are so numerous and of such quality that they resemble the works of angels rather than men. Ours are the paintings, the sculptures; ours are the trades sciences and philosophical systems."--
Gianozzo Manetti, 1452*

Introduction: why Italy? On rare occasion one comes across a period of such dynamic cultural change that it is seen as a major turning point in history. Ancient Greece, and especially Athens, in the fifth century B.C. was such a turning point in the birth of Western Civilization. The Italian Renaissance was another. Both were drawing upon a rich cultural heritage. For the Greeks, it was the ancient Near East and Egypt. For the Italian Renaissance, it was ancient Rome and Greece. Both ages broke the bonds of earlier cultural restraints and unleashed a flurry of innovations that have seldom, if ever, been equaled elsewhere. Both ages produced radically new forms and ideas in a wide range of areas: art, architecture, literature, history, and science. Both ages shined brilliantly and somewhat briefly before falling victim to violent ends, largely of their own making. Yet, despite their relative briefness, both ages passed on a cultural heritage that is an essential part of our own civilization. There were three important factors making Italy the birthplace of the Renaissance.

1) Italy's geographic location. Renaissance Italy was drawing upon the civilizations of ancient Greece and especially Rome, upon whose ruins it was literally sitting. During the Middle Ages, Italians had neglected and abused their Roman heritage, even stripping marble and stone from Roman buildings for their own constructions. However, by the late Middle Ages, they were becoming more aware of the Roman civilization surrounding them. Italy was also geographically well placed for contact with the Byzantines and Arabs who had preserved classical culture. Both of these factors combined to make Italy well suited to absorb the Greek and Roman heritage.

2) The recent invention of the printing press spread new ideas quickly and accurately. This

was especially important now since many Renaissance ideas were not acceptable to the Church. However, with the printing press, these ideas were much harder to suppress.

3) Renaissance Italy, like the ancient Greeks, thrived in the urban culture and vibrant economy of the city-state. This helped in two ways. First, the smaller and more intimate environment of the city-state, combined with the freedom of expression found there, allowed a number of geniuses to flourish and feed off one another's creative energies. Unfortunately, the city-state could also be turbulent and violent, as seen in the riot scene that opens Shakespeare's *Romeo and Juliet*. Secondly, the Italian city-states, especially trading and banking centers such as Venice and Florence, provided the money to patronize the arts. Therefore, the wealth and freedom of expression thriving in the urban culture of Italy both helped give birth to the Renaissance.

The Medici were a wealthy Florentine banking family and the primary patrons of Renaissance culture in the 1400s. While seen as the de facto ruling family of Florence, they were careful not to hold high offices and draw attention to themselves at this time. However, this wasn't as strange as it may seem, because Italian society was ruled through personal and family ties, much like the mafia, more than it was through official state institutions and offices. Cosimo de Medici (1389-1464) carefully built up the family fortune, making it possible to patronize the arts. He also established and protected the peace and balance of power in Italy through the Treaty of Lodi, thus creating the conditions for the Renaissance to flourish.

Lorenzo the Magnificent (above, 1449-92), Cosimo's grandson, carried on the family legacy of patronizing the arts. On Easter Sunday, 1478, he narrowly survived an assassination attempt during mass by the rival Pazzi family, although it did kill his brother, Giuliano. After this he assumed tighter control over Florence and married into a powerful Roman family to gain allies and influence outside of his home city.

Even more than his grandfather, Lorenzo is remembered as a patron of Renaissance artists, including Botticelli, Verrocchio, Leonardo da Vinci, and Michelangelo. Thanks to his astute diplomacy, Florence and Northern Italy experienced peace and prosperity.

Unfortunately, after Lorenzo's death in 1492, things fell apart with a severe religious reaction led by Savonarola taking over the city followed by an invasion by the French, which effectively brought Florence's golden age to an end.

Renaissance literally means rebirth, in this case the rebirth of classical Greek and Roman culture. The traditional view of the Renaissance was that it suddenly emerged as a result of the fall of Constantinople in 1453, which drove Greek scholars to seek refuge in Italy and pass classical culture to Italy. Historians now take this as too simplistic an explanation. For one thing, knowledge of Greek and Roman culture had never completely died out in medieval Europe, being kept alive during the Dark Ages in the monasteries, and during the High Middle Ages in the growing universities. Secondly, a revived interest in classical culture can be traced back to the Italian authors, Dante and Petrarch, in the early 1300's. Thus the Italian Renaissance was more the product of a long evolution rather than a sudden outburst.

Petrarch (1304-74) was an Italian scholar who is widely considered the “Father of Humanists”. Like the great medieval theologian, Thomas Aquinas, he saw religious faith and reason as compatible. Because of his love for classical culture, he supposedly coined the term “Dark Ages” to describe the early medieval era.

The Tuscan dialect in which he, Dante, and Boccaccio wrote would become the basis for standard Italian in the 1600s. Since he traveled across Europe for pleasure, Petrarch is also called the First Tourist, claiming to be the first man since Philip V of Macedon in the third century B.C.E. to scale a mountain as a recreational activity. During his travels, he went through monastery libraries and uncovered a

number of crumbling Latin texts, including previously unknown letters by Cicero.

In 2003, Petrarch's body was exhumed to use his skull to create an accurate image of what he looked like. Unfortunately, DNA tests showed that the skull fragments in his tomb belonged to someone else, although the body was likely his, since it bore the marks of injuries he was known to have suffered, including once being kicked by a donkey.

Still, the term "renaissance" has some validity, since its conscious focus was classical culture. The art and architecture drew heavily upon Greek and Roman forms. Historical and political writers used Greek and Roman examples to make their points. And renaissance science, in particular, relied almost slavishly upon Greek and Roman authorities, which was important, since this set up rival authorities to the Church and allowed Western Civilization to break free from the constraints of medieval thought and give birth to the Scientific Revolution during the Enlightenment.

New patterns of thought. Whether one sees the Renaissance as a period of originality or just drawing upon older cultures, it did generate four ideas that have been and still are central to Western Civilization: secularism, humanism, individualism, and skepticism.

1) Secularism comes from the word secular, meaning of this world. Medieval civilization had been largely concerned with religion and the next world. However, the new economic and political horizons and opportunities opening up for Western Europe in the High and Late Middle Ages got people more interested in this world. During the Renaissance people saw this life as worth living for its own sake, not just as preparation for the next world. The art in particular exhibited this secular spirit, showing detailed and accurate scenery, anatomy, and nature, whereas medieval artists generally ignored such things since their paintings were for the glory of God. This is not to say that Renaissance people had lost faith in God. Religion was still the most popular theme for paintings. But people were now finding other things worth living for in addition to the afterlife.

2) Humanism goes along with secularism since it makes human beings, not God, the center of

attention. The quotation at the top of this reading certainly emphasizes this point. So did Renaissance art, which portrayed the human body as a thing of beauty in its own right, not like some medieval "comic strip" character whose only reason to exist was for the glory of God. Along those lines, Renaissance philosophers saw humans as intelligent creatures capable of reason (and questioning authority) rather than being mindless pawns helplessly manipulated by God. Even the term for Renaissance philosophers, "humanists", shows how the focus of peoples' attention had shifted from Heaven and God to this world and human beings. It also described the group of scholars who drew upon the more secular Greek and Roman civilizations for inspiration.

3) Individualism takes humanism a step further by saying that individual humans were capable of great accomplishments. The more communal, group oriented society and mentality of the Middle Ages was giving way to a belief in the individual and his achievements. The importance of this was that it freed remarkable individuals and geniuses, such as Leonardo da Vinci to live up to their potential without being held back by a medieval society that discouraged innovation.

Besides the outstanding achievements of Leonardo, one sees individualism expressed in a wide variety of ways during the Renaissance. Artists started signing their paintings, thus showing individualistic pride in their work. Also, the more communal guild system was being replaced by the more individualistic system of capitalism, which encouraged private enterprise.

4) Skepticism, which promoted curiosity and the questioning of authority, was largely an outgrowth of the other three Renaissance ideas. The secular spirit of the age naturally put Renaissance humanists at odds with the Church and its purely religious values and explanations of the universe. Humanism and individualism, with their belief in the ability of human reason, raised challenges to the Church's authority and theories, which in turn led to such things as the Protestant Reformation, the Age of Exploration and the Scientific Revolution, all of which would radically alter how Western Europe views the world and universe. These four new ideas of secularism, humanism, individualism, and skepticism led to innovations in a variety of fields

during the Renaissance, the most prominent being literature and learning, art, science, the Age of Exploration, and the Protestant Reformation.

Literature and learning throughout the Middle Ages were centered on the Church. Consequently, most books were of a religious nature. There were Greek and Roman texts stashed away in the monasteries, but few people paid much attention to them. All that changed during the Renaissance. For one thing, increased wealth and the invention of the printing press created a broader public that could afford an education and printed books. Most of these newly educated people were from the noble and middle classes. Therefore, they wanted a more practical and secular education and books to prepare them for the real world of business and politics.

In response to this, new schools were set up to give the sons of nobles and wealthy merchants an education with a broader and more secular curriculum than the Church provided: philosophy, literature, mathematics, history, and politics. Naturally much of the basis for this new curriculum was Greek and Roman culture. Classical authors such as Demosthenes and Cicero were used to teach students how to think, write, and speak clearly. Greek and Roman history were used to teach object lessons in politics. This curriculum provided the skills and knowledge seen as essential for an educated man back then, and served as the basis for school curriculums well into the twentieth century. Only in recent decades has a more technical education largely replaced the curriculum established for us in the Renaissance.

Along the same lines, a more secular literature largely replaced the predominantly religious literature of the middle Ages. History, as a study of the past (Greek and Roman past in particular) in order to learn lessons for the future, was emerging. So was another emerging new discipline deeply rooted in history: political science. The father of this discipline was Nicolo Machiavelli (1469-1527). His treatise on governing techniques, *The Prince*, urges the prince to carry on with whatever ruthless means were at his disposal. This serves as a stark contrast to St. Augustine's concept of the "just war."

Another book of a secular nature was Castiglione's *The Courtier*, which spelled out the ideal education and qualities of a nobleman attending a prince's

court. Unlike the usually illiterate and rough mannered medieval noble, Castiglione's courtier should be versed in manners (such as not cleaning one's teeth in public with one's finger). This ideal of the well-rounded "Renaissance Man" harkens back to the Greek ideal of a well-rounded man and has continued to this day.

Art is the one field most people associate with the Renaissance since it saw the most radical innovations and breaks with the middle Ages. Since medieval art was religious in tone and for the glory of God, artists neglected mundane details, thus making the art seem flat and lifeless. Faces and bodies were cartoon-like, having no individual features or anything approaching accurate anatomical detail. Other details such as background, perspective, proportion, and individuality were all virtually unknown.

Renaissance art contrasted sharply with medieval art in all these respects. More paintings were on secular themes, especially portraits. And even the religious paintings paid a great deal of attention to glorifying the human form and accomplishments. Starting with Giotto in the early 1300's, Renaissance artists increasingly perfected and used such things as background, perspective, proportion, and individuality. In fact, Leonardo's detail was so good that botanists today can identify the kinds of plants he put into his paintings.

Although painting was especially prominent during the Renaissance, other art forms also flourished. For example, architecture broke somewhat with the medieval Gothic style during the Renaissance, relying more heavily on classical forms, in particular columns, arches, and domes as well as building on a massive scale. Possibly the supreme example of this is the dome of St. Peter's in Rome which was designed by Michelangelo and towers 435 feet from the floor.

Baptisteries

Italian custom prevented babies from entering a church until they had been baptized. Therefore

the front of an Italian cathedral was often graced with a baptistry. Thus the baptistry (such as that of Pisa above) became nearly an integral part of an Italian city's religious architecture along with the *campanile* (bell tower) and cathedral (*duomo*, meaning house [of God]).

Bridges

Bridges, were high-rent districts in cities because they were relatively safe from fire, since any urban fires trying to cross the river would bottleneck at bridges where efforts could be concentrated to contain them. Also, they were probably cleaner, since they had their own natural "sewer systems" flowing underneath. In addition, they were easily supplied by water transport, and caught any business crossing the river.

Music in the Renaissance saw developments that would later blossom into classical music. Instruments were improved and the whole family of violins was developed. Counterpoint (the blending of two melodies) and polyphony (interweaving several melodic lines) also emerged during this period.

Science saw little advancement, but it was also important for future developments. In particular, classical authorities were discovered who contradicted Aristotle, whose works were accepted by the Church almost as gospel. Finding conflicting authorities forced Renaissance humanists to ask questions that would lead to developing new theories, which in turn would lead to the birth of modern science in the 1600's and 1700's.

The Age of Exploration also showed Renaissance ideas at work. It was secular in its interest in the world. It certainly displayed skepticism by challenging accepted ideas about the world. And the fact that it pitted individual captains against the forces of nature shows it was both humanistic and individualistic.

The Protestant Reformation was one other result of the Italian Renaissance. The spirit of skepticism challenged the authority of the Church, thus opening the way for much more serious challenge later posed by the Protestants. The Protestant Reformation, in turn, would pave the way for new

patterns of thought in social, political, economic, and scientific matters.

Starting in 1495, Italy's political disunity would attract various outside powers, triggering a devastating round of wars and invasions that ended its most innovative cultural period. However, in the process, the invaders took the ideas of the Italian Renaissance back to Northern Europe and sparked what is known as the Northern Renaissance.

Why Florence led the Renaissance.

Initially, Florentines had gained their wealth as pro-Papal Guelphs who had been allowed to collect Church taxes for the popes. Using this revenue, they developed one of the premier woolen industries in Europe.

Then the Black Death hit in 1347, and Florence, like other cities, suffered horrendous population losses and with that severely reduced tax revenues. To compensate for this, the Florentines heavily taxed the Church, which reacted by excommunicating the city. All this seems to have accomplished was to anger the Florentines against the Church. As a result, Florence had a much more secular outlook that not only tolerated, but even encouraged new ideas, thus making it the center of the Italian Renaissance.

Leonardo da Vinci

Leonardo da Vinci (1452-1519) is arguably the most recognizable figure of the Renaissance, largely because he cut against the grain of the old corporate mentality of the middle ages more than anyone else. Born in the village of Vinci near Florence, he received little formal education (none in Greek), which kept him out of the inner circle of humanists in Florence. However, Vinci's rural setting got him involved in nature and observing everything in minute detail: rocks, water, clouds, plants, and animals.

At age 13, he was apprenticed to Verrocchio, one of the top painters and sculptors of the day in Florence. Such training involved more than slapping paint on a canvas and pouring bronze. An artist also had to know what pigments to use for certain colors and how to mix them properly, as well as how to prepare clay, make molds, and prepare bronze for casting statues. Beyond that,

he had to study human anatomy, which might include attending dissections of human cadavers.

Leonardo's first painting was the angel to the far left in Verrocchio's *Baptism of Christ*. What made it so startling and realistic was the angel actually seemed to be looking at someone rather than off into empty space. Supposedly, Verrocchio gave up painting after seeing the technical genius of his apprentice.

Because of his lack of acceptance into the inner circle of Medici humanists, Leonardo went to Milan where its ruler, Ludovico Sforza, hired him as the court musician and to make costumes, props, court portraits, and, in one instance for a French royal visit, a Lion automaton that reared on its hind legs and spilled lilies (symbol of the French monarchy) from its breast.

Leonardo's fascination with robots didn't stop there. He built a second robot lion in 1515 that walked and moved its head, and designed a third one that was finally built in 2009 based on rudimentary sketches in his notebooks. Powered like a clock by winding it up with a crank from its side, it can walk ten paces, turn its head, move its tail, and bare its fangs. In addition, Leonardo had designs for a human robot that could even play drums, with a device for controlling the tempo.

To a large extent, Leonardo's move to Milan was a turning point in the Renaissance away from the pioneers who looked for the ideal man in the classics and antiquity. By contrast, his real interests lay in the structure of things and how the world worked, so living in Milan gave him more freedom to explore these interests: drawing maps, casting cannons, installing central heating, designing war engines, irrigation systems, palaces, and whole new cities, along with a multitude of various other schemes.

Leonardo had a whole new vision of the world and its underlying realities. The window to this vision was his collection of notebooks, which were full of sketches taking nature to pieces, not to copy it, but to understand it. In his notebooks we find anatomical drawings, especially of blood

vessels and hollows in the head that compare favorably to modern x-ray photos.

His fascination with flight produced ideas for the parachute, the hang-glider, and even a design for an aerial screw helicopter (below). While his design for the helicopter (aka, ornithopter), would not have provided the needed lift, that of his hang-glider has been proven to be valid. In 2008, a Japanese inventor, Gennai Yanagisawa, inspired by Leonardo's designs for the helicopter marketed a personal helicopter, the GEN H-4, for \$58,250.

Other ideas for inventions included machines for grinding needles and mirrors, a rolling mill, an automatic file cutter, an instrument for measuring wind speeds, a steam cannon, a portable bridge, the machine gun, and the tank (which his age could not have powered.) Supposedly, 150 years before Galileo, he even saw how a pendulum could be used to keep time.

In 1482 Leonardo was commissioned to cast a bronze equestrian statue of his patron's father, Francesco Sforza of Milan. It was supposed to be the largest equestrian statue in the world, being twenty-four feet high and requiring seventy tons of bronze. Despite its massive scale and the problems associated with bronze statues, modern research shows that Leonardo had the fluid dynamics accurately calculated, even designing special furnaces so he could cast the horse in a single pouring of 165 seconds.

Unfortunately, after seventeen years of research and building a clay model for the project, war broke out and the bronze, as all too often happened, was requisitioned for cannons. While occupying Milan, French crossbowmen used Leonardo's clay model for target practice and shot it to pieces, ending any chance of him completing his epic project. One likes to imagine the diverted bronze getting vengeance as cannons against the impudent crossbowmen on a future battlefield in Italy.

Luckily for Leonardo, a group of Americans, using his somewhat incomplete drawings for the project, decided to make his horse. On September 10, 1999, exactly 500 years to the day after French crossbowmen demolished his clay statue, the finished bronze statue was officially unveiled in Milan.

In the end, few of Leonardo's ideas made it beyond his notebooks. Similarly, he completed only about a dozen paintings in his lifetime, a source of great frustration to his employers. As Pope Leo X, one of his many patrons put it: *"This man will never do anything, for he begins to think of the end before the beginning."*

So what was Leonardo's contribution? To a large extent, it was his eye for detail. Renaissance artists before Leonardo had included secular details, such as plants and animals, to make their paintings seem more realistic, but when viewed from up close, they generally would be hard or impossible to identify as particular species.

After this, thanks to the background work Leonardo did in observing and sketching in his notebooks, we can identify the exact species of plants in his paintings. And once he had raised the bar of accuracy for details to this level, no artist worth his salt could afford to aspire to less.

This had an even more profound impact on science (or natural philosophy as they called it then), which operated largely in the realm of vague or highly generalized theories. With Leonardo, we see greater reliance on precise observation and recording of data and phenomena, a major turning point in the history of science.

A key event in this respect was the publication in 1542 of Vesalius' *De Fabrica*, the first accurate book of human anatomy. This is seen as one of the key events in medical history, because for the first time, thanks also to the printing press, medical students across Europe could get an accurate look at the inner workings of human anatomy. The fact that it was students of the famous Venetian artist, Titian, who did the diagrams also underscores the fact that people didn't pigeon-hole the various disciplines, in this case art and science, into separate categories.

Thus Leonardo's detailed art was a crucial factor in the history of science.

The Prince

Machiavelli's *The Prince*, was written in the context of the vicious wars and political intrigue plaguing Italy since the French invasion in 1494. It still sparks controversy for the seemingly ruthless techniques the author advocated for a prince to survive such conditions.

For example, when addressing the question of whether it is better for a ruler to be loved or feared, Machiavelli weighs in on the side of fear, using the logic that one can control whether someone fears him more than he can make that person love him. However, he says that fear is quite compatible with an absence of hatred and that a ruler can best avoid being hated by refraining from stealing his subjects' property (including women, who were seen as a virtual subset of property). In fact, he says that taking a subject's property is worse than killing his loved ones, since memories of loved ones will fade while poverty will be a constant reminder of how a ruler took one's goods.

Even today, we use the term *Machiavellian* to describe a strategy of cold-blooded logic seemingly devoid of any morals.

The Gates of Paradise

Besides the initial outbreak of plague that hit Florence in 1347, wiping out 60% of its population, it was hit again in 1363, 1374, 1383, 1390, and 1400 when 12,000 people, some 20% of its population, died. Extreme measures were taken, such as violently ringing the church bells, discharging firearms into the air, and burning ox horn and lumps of sulfur in the streets, the theory being that the intense stench would drive off the plague. One thing it did accomplish was convincing lots of sparrows to drop dead from the trees and rooftops. Also, for whatever reasons, the plague subsided.

However, a new menace threatened Florence, Giangaleazzo Visconti, duke of Milan, against whom Florence had fought a war ten years earlier. Ginger bearded, cruel and ambitious, his coat of arms and coins showed a coiled viper crushing a struggling man in its jaws. In 1385 he had seized power in Milan by imprisoning and then poisoning his uncle and father-in-law, Bernabo Visconti. After that, he bribed the emperor Wenceslas IV to grant him the title of duke of Milan.

By 1401, Visconti had subdued Pisa, Siena, and Perugia, isolating Florence and cutting it off from trade with the sea. He even prevented Florence from importing wire to make brushes for carding their wool.

Having survived the plague, but now facing this second threat, the Florentines decided both to thank and appease God by dedicating a new set of bronze doors on their baptistery. To that end, they held a contest to see which artist was best qualified for the contract. Two finalists were chosen: Filippo Brunelleschi and another young, unknown goldsmith, Lorenzo Ghiberti. They were given one year to complete a 17' by 13' bronze panel depicting Abraham's sacrifice of Isaac. In the end, the judges couldn't decide between the two pieces and tried to award the contract to the two men jointly. Brunelleschi, being a somewhat cantankerous loner refused these terms, so Ghiberti took on the task.

In the meantime, just as he was about to crush Florence, Visconti suddenly died. The Florentines, feeling like David who had defied and defeated Goliath (with a bit of divine help) would later commemorate their defense of liberty with statues of David by three famous artists: Donatello, Verocchio, and Michelangelo.

Also, because of this seemingly miraculous deliverance, the Florentines spared no expense on the bronze doors of their baptistery. The north doors of the Baptistery depicting 28 scenes from the life of Christ took Ghiberti over twenty years to finish (1403-25). The completed doors weighed 17 tons and cost Florence 22,000 florins, nearly equal to the city's annual military budget.

The East doors (above, with a panel on the Drunkenness of Noah), which took Ghiberti over another quarter century to complete (1425-52), depicted ten scenes from the Old Testament. They were so spectacular that Michelangelo called them the “Gates of Paradise.”

A major issue with works of art is the ravages of time. This is especially the case with art that is exposed to the outside elements. Even efforts at restoration can do more harm than good. Such was the case with earlier attempts to restore the Gates of Paradise. Finally, in 2000 laser techniques developed for this purpose were used to restore Ghiberti’s panels. They are kept in a nearby museum in a plate-glass box, into which inert nitrogen is pumped to prevent future decay. Exact replicas of the panels hang on the Baptistery doors so tourists can see them in their original context.

Florence’s Duomo: Santa Maria del Fiore

In 1296, the Florentines, growing wealthy from the wool trade, laid the foundation for a new cathedral intended to be the largest in Christendom, with a dome surpassing that of the Hagia Sophia in Constantinople by twelve feet. Entire forests were needed to provide its timber.

Despite the Black Death in 1347, which destroyed 80% of Florence’s population, the cathedral’s nave and façade had been completed by 1355. However, there remained the problem of how to build the huge dome. Thus the wool merchants’ guild responsible for building and funding the cathedral resorted to the tried and true method of a competition to see who could present the best design.

The normal practice was for architects to build scale models made from wood, stone, brick, or even clay or wax. Such models were often highly detailed and large enough for judges to walk inside. For example, the brick and plaster model of the cathedral for Bologna was 59 feet long.

Below: Brunelleschi’s model of how his dome would look.

After rejecting a Gothic design as being ugly and awkward, its flying buttresses providing visible support, the Florentines adopted Neri di Fioravanti’s design based on his model which was 15 feet high and 30 feet long and proudly displayed in one of the side aisles of the growing cathedral. (A few years later, it collapsed under its own weight, not a good sign.)

Neri’s dome would be ten feet wider than previously planned, making it wider than the Pantheon in Rome. Sitting on a 30-foot high tambor (drum) that rested on an octagonal structure of walls 140 feet high, the dome itself would *start* rising at 170 feet. By comparison, the highest Gothic choir at Beauvais started at 126 feet and rose to 157 feet.

Based on a medieval Persian design widely used in Arabic architecture, it actually would consist of two domes, with a tall outer shell to give the church impressive height and a shallower inner shell that would provide partial support for the outer dome and be better suited to the interior proportions of the church. Furthermore, unlike hemispheric domes, such as the Pantheon in Rome, this dome was to be pointed like a Gothic arch with four interpenetrating buttresses or vaults.

Now all they had to do was figure out how to build it.

In fact the church sat for fifty years without any sort of dome until 1418 when another public competition was held to see who could come up with the best design for completing Neri’s model. The winner was Filippo Brunelleschi.

One major problem was the vast amounts of timber centering needed to support the masonry for the 12 to 18 months it took for the mortar to dry. If the centering were removed too soon, it would weaken the dome, running the risk of it collapsing. However, long-term pressure on the centerings could cause their wood to warp under the weight of the masonry, which would then shift, also bad for the dome. Timber was expensive, being scarce and difficult both to cut (without power saws) and transport.

Removing the centerings was also a hazardous task, in case the mortar wasn't dry yet. One proposal was to support the masonry by building a 300-foot high dirt mound in the church, a technique used in smaller Romanesque churches. One warden sarcastically suggested planting coins in the mound, which, when the time came, would encourage poor people to remove the dirt like pigs rooting for acorns.

Brunelleschi's very radical proposal was to forego wooden centerings altogether. Some considered him a lunatic for making such a suggestion. According to legend, he convinced the panel of judges to award the contract to whomever could stand an egg on its end. He then cracked an egg on its end and stood it up. Whatever the reason, he got the contract.

Precise calculation of the angle of the pitch needed for the two domes to rise along the eight sides of the octagonal drum was another major problem, especially since it had to be built so high up. Brunelleschi adopted a method by architects of Gothic cathedrals where they would draw templates on the ground to the precise measurements of the pitch of the vault and then build the centerings from that once they had all sides matching up on the ground.

Similarly, Brunelleschi cleared an area by the Arno River for such a project. Although he wasn't going to use centerings, he did make a guide between the two shells that could guide both domes as they went up.

Another problem was that the dome's bricks weren't laid in horizontal courses, but angled in at ever increasing angles as the dome rose and its radius shrank from 70 down to 10 feet. Eventually they would lean in at a 60° angle.

Brunelleschi had to invent all sorts of devices for constructing Santa Maria del Fiore's dome. Possibly the most important was the reverse gear which allowed his crane to raise and lower loads without having to unhitch the oxen driving it and re-hitch them on the opposite side of the turnstile.

The famous biographer of Renaissance artists, Giorgio Vasari said of Brunelleschi's machines:

"...by using counterweights and wheels for lifting he made it possible for a single ox to raise a load so heavy that previously it would hardly have been possible for six pairs of oxen to move it." These contraptions were so amazing that people paid to ride them like carnival attractions, until the Florentine government called a halt to the practice, since it was interrupting progress on the building.

Except for the lantern to hang from the center of the dome, the cathedral was finished by 1436 shortly before Brunelleschi died. Until the completion of St. Peter's Basilica in Rome, it had the largest dome in the world, a remarkable accomplishment for such a small city.

The world's greatest practical joke

Brunelleschi was also known for his elaborate practical jokes. When a good-natured carpenter, Manetto "il grosso" (the Fat) irked him for missing a social gathering, Brunelleschi enlisted the aid of a number of people to convince Manetto he was actually someone else.

One evening, after Manetto left his shop, Brunelleschi picked his lock, went inside, and barred the door. When Manetto returned and couldn't get in, Brunelleschi, who also was a great impersonator, claimed *he* was Manetto and told the real Manetto to go away. Manetto, half-convinced by Brunelleschi, left and was then addressed as another man, *Matteo*, by several people, including the artist Donatello and a bailiff who arrested him for gambling debts. Manetto spent an uncomfortable night in jail, convinced the mistaken identity would be taken care of in the morning, although even his fellow prisoners were addressing him as Matteo.

The next morning, two men, the real Matteo's brothers, showed up, bailed Manetto out as Matteo and berated him for his gambling debts as they took him to Matteo's home where everyone else insisted he was Matteo. That night, Manetto was drugged by a potion, carried to his own home and put to bed, but with his head at the foot of the bed. When he awoke in this confusing position he noticed all his tools had been rearranged. Then Matteo's brothers showed up and addressed Manetto by his real name, claiming Matteo had been claiming to be

Manetto for the last day. Soon afterward Matteo himself showed up and confirmed he had had this dream that he was Manetto for a day and as Manetto had rearranged his tools. By this time, Manetto was convinced that he had indeed switched identities with Matteo for a day.

Mind Your Manners: Renaissance etiquette according to Baldassare Castiglione

While we typically associate the Italian Renaissance with Florence, especially in the 1400s, other Italian cities also served as cultural centers, especially after the French invasion in 1494. One such place was the tiny city-state of Urbino under duke Federigo di Montefeltro who ruled from 1444-82. He was a highly successful condottieri (mercenary captain) in his early years and an accomplished scholar and patron of the arts later in life, largely to expiate his earlier sins as a soldier. His court was a model of its time and thus served as the setting for Baldassare Castiglione's book on court etiquette, *The Courtier*.

Some advice concerning Renaissance etiquette according to Castiglione's *Courtier*

- Don't offer someone a fruit from which you've taken a bite.
- Don't tell sad or gruesome stories at parties or mealtimes. Politely change the subject to something more cheerful if someone starts talking like this.
- Bragging about honors, wealth, or your intelligence doesn't go over so well either.
- Do not speak while yawning or yawn while speaking.
- Don't clean your teeth with your napkin or finger. That also goes for your nose.
- Don't lie all over the dinner table or fill both sides of your mouth with so much food that your cheeks stick out like a stuffed chipmunk
- Do not undress, comb, or wash your hair in front of others
- Don't stick out your tongue, rub your hands together, or groan out loud
- Do not talk too much especially if you don't know what you're talking about.
- Never blow your nose and then look inside your handkerchief, as if pearls or rubies had dropped out of your head, because they probably haven't.
- The ideal noble should be educated, quick-

witted, and physically fit, especially in the ability to throw rocks to impress the commoners.

The Renaissance in Rome

St. Peter's Basilica in Rome

By 1425, the "Babylonian Captivity at Avignon, Great Schism (1378-1429), Black Death, and feuds between powerful Roman families such as the Orsini and Colonna had brought the Papacy to its lowest point since the tenth century. An example of this was a mercenary named Braccio who liked to drop his enemies from towers or into boiling oil.

However, the end of the Great Schism in 1429 saw Rome reborn, not so much spiritually as culturally. The new pope, Martin V (1417-31) from the Colonna family was a strong personality who checked crime and violence and stimulated new architectural building. With the popes back in Rome, money from church taxes, court fees, and religious tourists (AKA pilgrims) came flooding back into Church coffers.

Not that everything was stable. For example, when Eugenius IV (1431-47) fled from Rome to Florence, his bishop, Vitelleschi who was left to restore order instead destroyed property and slaughtered his enemies until he was finally poisoned, maybe by Eugenius himself.

Nicholas V (1447-55) was largely responsible for starting the Roman Renaissance. Being an avid scholar, he built a huge collection of books, employing hundreds of copyists and the best scholars, such as Lorenzo Valla, to edit and copy not just Latin works, but also Greek ones that were starting to make their way to Italy after the fall of Constantinople in 1453. Nicholas paved the way for pagan Greek and Roman works of literature and secular studies in general to be accepted by the Church. He even paid 10,000 gold pieces for a good translation of Homer. In

1420, the Papal collection numbered barely 300 books. By Nicholas' death, the Vatican library contained 9,000 volumes and had attained the status as of one of the world's greatest libraries. As pope Pius II would say of the learned Nicholas: *"What was unknown to Parentucelli (Nicholas) lay outside the sphere of human learning."*

Nicholas also wanted to build Rome as a great city, reinforcing its fortifications, paving its main streets, and improving its water supply by restoring the old Roman Aqua Virgo aqueduct, which emptied into a basin later made into the Trevi Fountain.

But his real goal was to rebuild the Vatican, in particular St. Peter's basilica. To that end and showing little apparent regard for antiquity's ruins, he tore down the old basilica and stripped the Coliseum of 2522 cartloads of marble along with marble from the old Circus Maximus, Roman Forum, Arch of Titus, and temple of Venus. Completion of the new St. Peter's and a papal palace protected by the Castel de Angelo would have to wait for later popes. But Nicholas got it started.

Sixtus IV (1471-84) was a pleasure loving, but refined pope who built much of Renaissance Rome. Being born into poverty, he ruthlessly pursued wealth and luxury once given the chance, as the following description of one of his banquets indicates: "Before them were carried wild boars, roasted whole in their entire hides, bucks, goats, hares, rabbits, fish silvered over, peacocks with their feathers, pheasants, storks, cranes and stags; a bear in its skin, holding in its mouth a stick; countless were the tarts, jellies, candied fruits, and sweetmeats. An artificial mountain was carried into the room, out of which stepped a liveryman w/gestures of surprise at finding himself in the midst of such a gorgeous banquet; he repeated some verses and then vanished. Mythological figures served as covers to the viands placed on the table. The history of Atlas, of Perseus and Andromeda, the labors of Hercules were depicted life-size on silver dishes. Castles made of sweetmeats and filled with eatables were sacked and then thrown from the loggia of the hall to the applauding crowd. Sailing

vessels discharged their cargoes of sugared almonds..."--Daughter of the king of Naples

Sixtus also wanted to rebuild Rome as a great city, reinforcing its fortifications, widening and paving its main streets, and building bridges. By this time, Rome had only three of the ancient city's thirty triumphal arches left standing and one of its eleven aqueducts still functioning. Therefore, Sixtus restored the old Roman Aqua Virgo aqueduct to improve the city's water supply, until then drawn from the yellow, polluted and unhealthy Tiber River. The cistern for this restored aqueduct would later be transformed into the Trevi Fountain. He also had the Sistine Chapel built which Michelangelo would so famously adorn. To encourage growth of the city, he gave land to all who would build houses and palaces there.

As a patron of the arts, he brought in many famous painters, notably Signorelli, Botticelli, Perugino, and Ghirlandaio who formed the artist's guild of St. Luke. He also made an important contribution to science with a papal bull allowing bishops to give unidentified bodies and those of condemned criminals to physicians and artists for dissection. This would be a major step forward in the development of Vesalius' anatomy book that would help anatomy students across Western Europe.

Unfortunately, for security, the popes needed to consolidate their hold on the Papal States, for which they hired the best mercenaries of the day, such as Francesco Sforza and Federigo Montefeltro. However, as Papal power grew, it made more enemies and needed strong popes to maintain it. Indicative of this were the popes Alexander VI and Julius II.

Alexander VI (1492-1503). Rodrigo Borgia, whose family name became a byword for papal corruption and violence took the papal name, Alexander VI. Although an able administrator, he probably bribed his way into the papacy, reportedly engaged in wild and expensive orgies, and also made the mistake of getting involved in the big power politics that tore Italy apart starting with the French invasion in 1494. He also spent a lot of money and energy seeking lands and power for his illegitimate children,

most notably Cesare Borgia, whom he made cardinal at age 18, and his equally notorious daughter, Lucretia.

Pope Julius II (1503-13) was the son of a fisherman, who took full advantage of his rapid rise in the Church. As a cardinal, he had three magnificent palaces stocked with girlfriends, at least one of whom repaid him with syphilis, a disease reputed to be very popular with priests.

He took his name from a fourth century pope, but is associated more with Julius Caesar as a warrior. Like Ivan IV of Russia, he was known as the “Terrible” for his rages of punching or thrashing underlings with a stick. However, his wars are what he is most remembered for. According to a poem by Erasmus, when St. Peter wouldn’t let Julius into heaven, he went back to earth, got an army and stormed the pearly gates.

Papal beards. During the siege of Ferrara, Julius came down with a fever and grew a beard during his convalescence, something that was nearly as unheard of among popes as leading armies into battle. The tradition of clean-shaven popes went back to 1031 when the Council of Limoges concluded for some reason that St. Peter was clean-shaven. Likewise priests were prohibited from having beards so that the communion wine wouldn’t get caught in their whiskers.

Although an able warrior, Julius could barely survive in the constantly shifting politics of the big powers (Spain, France, and Holy Roman Empire) using Italy as their battleground. He is probably best remembered for enlisting Michelangelo to paint the ceiling of the Sistine Chapel. He also laid the foundation stone for St. Peter’s Basilica in 1506.

Julius died in 1513. He was actually improving from illness until doctors gave him medicine containing powdered gold, which killed him.

Renaissance Rome. Even if Rome didn’t start the Renaissance, it produced cultural works on the grandest scale. While expensive, these monuments drew more pilgrims who, overwhelmed by the city’s “religious” splendor, often didn’t care about the popes’ reputed scandals and illegitimate children.

Not that behavior in the streets was any better than in the papal palaces. Rome’s population of 50,000 had an estimated 3,000 priests and 7,000 prostitutes. Carnival especially brought out the worst excesses. Bulls were released in the streets to be slain by men on horseback. Condemned criminals were executed by men in harlequin outfits. There were reportedly prostitute contests, races between hunchbacks and cripples, and even the “racing of the Jews” who had to run down the streets in bizarre costumes while being prodded and insulted by the crowds.

Renaissance women

During the Renaissance women, in particular daughters of the rich, usually played a subservient and largely invisible role as wives and mothers. Their status as bearers of (hopefully male) children and little else is reflected in one man’s advice: “*Buy the Adimari girl. She’s good meat with lots of flavor.*” Indicative of this low status was the ring ceremony where the wedding contract was signed, specifying the dowry the bride’s family had to pay to get the groom’s family to take her off their hands. Juliet’s betrothal at age 13 in Shakespeare’s play to a man twice her age and without her consent was typical among upper class urban families.

Marriages were often not consummated until the bride had moved to her husband’s house, which might take weeks or months. On the happy couple’s first night together, it was customary for wedding guests, usually well lubricated with wine, to burst in on the happy couple to make sure the marriage had been consummated and that the bride had been a virgin.

Sometimes, especially among royalty, weddings were performed by proxy where one or both of the primary participants was not present and was represented by a stand-in. To Consummate

such marriages, the proxy couple would lie in bed and let their legs touch.

During a birthing, men were excluded from the room, the main facilitators being midwives who, having extensive knowledge of medicinal herbs, probably provided the best medical care of the day. In fact, if I had my choice between a midwife with a wealth of practical knowledge about medicinal herbs and a doctor trained in the theory that our health depended on the balance of four mysterious humors in our body and the way to restore that balance was through enemas, making me vomit, or taking blood out of my body, I'd take the midwife.

Although childbirth (above) was a risky event, its dangers have likely been exaggerated by Hollywood and novels that focus on royalty and the rich, who were particularly prone to puerperal, or “childbed”, fever. This was an infection typically passed on to mothers and newborns by physicians who didn't wash their hands. Since only the rich could afford such physicians, who were always male, and the poor had to rely on midwives, who did wash their hands, upper class women and their newborns were probably more exposed to the infection and died at much higher rates.

Women were also confined by the fashions they had to wear. In the sixteenth century, Catherine de Medici introduced the corset, which would leave women gasping for air for centuries. According to Catherine, the ideal waist size was 13 inches, a standard which Elizabeth I in her coronation portrait seems to have attained.

Throughout history, the “ideal” figure went through radical mutations in fullness, flatness, position and cleavage. Eighteenth century Europe, in particular, switched breast vogues with wild abandon. However, women, armed with whalebone, iron and padding, tried their hardest to meet the current dictates of fashion.

The early corset ended just below the bust, thus pushing the breasts up. The added lift was not enough for some, however. Toward the end of the 1700s, an early version of the Miracle Bra pushed the bust high — sometimes near the chin. Later, corsets flattened breasts by squeezing the upper body. Corsets were made of cloth,

whalebone and metal. One was even made entirely of metal — the “coat-of-armor” corset.

Up until the twentieth century, daughters of the rich were commonly forced to wear corsets, and boarding houses scolded girls who complained — after all, rib and organ pain usually disappeared after a few weeks.

Corsets eventually became controversial for health reasons, including fainting and muscle atrophy. Many women, however, defended corsets: “*(If) the various organs are prevented from taking certain form or direction, they will accommodate themselves to any other with perfect ease,*” said one woman in a letter to *Queen*, an 18th-century magazine.

Another popular torture/fashion trend for women was tweezing the hairlines to create an artificially high forehead and the image of height. To that effect, they wore ridiculously high platform shoes that, if nothing else, kept them from running away from their men.

One of the few circumstances allowing women to participate in the high culture of the Renaissance was when a ruler had no sons and invested in the education of his daughters. Such a woman was Isabella d'Este, one of two daughters of the Duke of Ferrara who gave his daughters an excellent humanist education. As the wife of the condottiere and marquis of Mantua, Francesco Gonzaga, she often acted as his regent when he was gone to war, trying to fix his many diplomatic mistakes. After his capture by the Venetians in 1509, she ruled Mantua on her own making Mantua one of the most splendid courts in Italy through her patronage of the arts.

Sofonisba Anguissola (c.1532–1625) was one of the first women to be recognized as a truly accomplished artist in her own right. For the sake of decency, women were restricted in subject matter to portraying women, children, and men to whom they were related.

77. A BRIEF OVERVIEW OF WESTERN PAINTING (c.1400-1945)

Introduction. Doing such a brief overview of Western painting may seem a bit ludicrous, but it does show how art and other threads of historical development influenced each other throughout history.

The Renaissance (c.1400-1600) is a good place to start, because no historical era has been better reflected in its art. Starting sometime around 1400, a more secular approach was capturing the age's spirit and imagination. Renaissance paintings reflected this move toward a more secular realism in two major ways. One was subject matter, many paintings portraying classical Greek and Roman history and legends or being portraits of individuals. The second way painting reflected the spirit of the age was through technique. The use of such things as perspective, proportion, shading, and closer attention details helped create paintings of striking realism compared to anything since the Roman Empire. It should be said that the single greatest patron of the arts was still the Church and religion was the most common theme, but even those paintings reflected the new techniques sweeping across Renaissance Europe.

Perugino's *Christ Giving the Keys of Heaven to St. Peter* (c.1481) is a perfect example of the use of a vanishing point and linear perspective to give a 3-d sense of depth to a picture

The Baroque. By the 1600s, the Renaissance had helped produce the Protestant Reformation, which gave rise to an age of Religious Wars (c.1560-

1648). This was a turbulent and violent age, and the art reflected it. Even the term Baroque, meaning twisted or distorted, suggested dramatic and even chaotic motion. However, there was also more portrayal of everyday life and common people in paintings by such artists as Caravaggio in Italy and a number of Dutch painters. The Dutch Republic became the most prolific center for art in the 1600s, since its wider distribution of wealth created a much broader market for art. Even moderately prosperous tradesmen could afford small paintings, thus supporting some 500 Dutch artists, so many that some were able to specialize in certain genres of art previously considered unworthy of being painted: landscapes, seascapes, still lifes, and interiors of homes.

Despite being a somewhat serene event, *Moor Presenting Lady with a Parrot* Berchem maintains dramatic tension by means of the clouds in the background.

The Rococo (1700s). The age of religious wars helped lead to two things, one cultural and the other political. Culturally, the seemingly endless fighting had discredited religion and fostered a more secular outlook. The result was the age of Enlightenment that especially stressed reason, secular philosophies, and the newly emerging modern sciences. Politically, the turmoil of the last century created a desire for more stability, giving rise to the Age of Absolutism along with the prominence of the nobles and their values. Together, these produced a very ornamental style of art known as Rococo that typically had lighter, sensual, and more secular themes to suit the nobles' tastes.

Fragonard's *Bathers* perfectly reflects the frivolous paintings favored by noble patrons in the 1700s

Liberty Leading the People by Eugene Delacroix shows the romanticized image people in the 1800s had of Liberty their nation., which typically were personified as a woman to symbolize their romanticized purity.

However, by latter half of the 1700s, many people were reacting against the cold rationality of the Enlightenment and the frivolous values of the nobles. A new spirit crept into the art, stressing romance over base sensuality and sentimentality over cold reason. Typical of the latter were the paintings by Jean-Baptiste Greuze, showing dreamy looking young women holding fluffy lambs or weeping over their dead pet birds. In reaction to the corrupt values of the old regime there was also more stress given to civic virtue and patriotism, setting the stage for the French Revolution.

Romanticism, Neo-classicism, and Realism (early 1800s). The two new ideas of the late Enlightenment, sentimentalism and emphasis on civic virtue and patriotism, were expressed in two new schools of art. One of them, Romanticism, which was also seen in the literature and music of the time, stressed our emotional side, idealized nature and everyday themes through the use of broad brushstrokes of color. Critics called the Romantics' work sloppy since the figures were often kind of blurry instead of precisely drawn (e.g., Turner's "Rain, Steam, and Speed"). The Romantics' more down to earth themes also reflected the more democratic spirit sweeping across Europe at the time.

By contrast, the other school of art, Neo-classicism, created precisely painted images from Greek and Roman myth and history to portray the selfless sacrifices of past heroes in order to inspire present day patriots. Jacques Louis David was especially prominent, doing paintings of such events as the *Oath of the Horatii* (below) from Roman legend and Leonidas at Thermopylae Pass from Greek history. However, as an apologist for the French Revolution and then for Napoleon, he adapted his style to contemporary events such as the Tennis Court Oath and the death of Marat during the Revolution.

As the century progressed, the two styles each contributed to a third school of art: Realism. Painters such as Gustave Courbet combined the realistic techniques of Neo-classicism with the contemporary themes portrayed by the Romantics. Thus Courbet did paintings of such mundane things as a peasant funeral and a dead trout, topics that

critics considered beneath the dignity of portraying on canvas. However, this helped set up the next big movement in painting.

Gustave Courbet (1819-77), *The Burial at Ornans* (1849-50). The Realists criticized both the dramatic exoticism of the Romantics and the stiff moralizing of the Neo-Classicalists with starkly realistic portrayals of everyday scenes and common people. This huge painting of a peasant funeral aroused great indignation for its portrayal of such a humble theme on an epic scale.

The second great art revolution: Impressionism and Post Impressionism (c.1863-1900). In the nineteenth century, the industrial revolution produced two new developments that dramatically changed European painting. The first, tin tubes of pre-mixed paint, eliminated the need for artists to mix all their paints in their studios, thus freeing them to take their craft outside and paint on location. Previously, the closest artists had come to this was drawing rough sketches on location and then doing paintings of those sketches in the studio. The second innovation was the camera, which mechanically produced images with photographic accuracy. This freed artists from slavishly having to recreate a scene exactly as it looked. Instead, they could approach their subjects in increasingly non-representational ways.

The Impressionists, such as Monet and Renoir, tried to free themselves from intellectualizing a subject as solid objects (e.g., trees or tables) and painting each of those objects separately. Instead, they tried to rapidly capture the individual impressions of light in a scene, which together would add up to a picture of that scene, but in a different way from a photograph. Now the emphasis was on the fleeting impressions of light and the emotional impressions they left with the viewer. This technique was

especially effective in portraying such things as smoke, rippling water, flags blowing in the breeze, and the splash of colors seen in a bouquet of flowers. Not since the Renaissance had such a revolutionary new approach to art been taken, and the critics and public didn't like it or accept it for nearly two decades. But the Impressionists had opened the door to any number of new approaches to painting.

Gare St. Lazare by Claude Monet shows how the less precise technique of the Impressionists could be used to capture the fleeting moment of smoke emerging from steam locomotive.

Thus the last decades of the nineteenth century saw a number of new approaches to art, sometimes lumped together as Post Impressionists, such as Vincent Van Gogh, whose *Night Café* is shown below. On the one hand there was the scientific or geometric approach, epitomized by Paul Cezanne's attempts to reduce a scene to a collection of basic geometric shapes. Georges Pierre Seurat created whole paintings of tiny colored dots mixed together that would add up to a picture. Paul Gauguin experimented with using solid fields of color rather than shading to create an effect. Another school of art originating in the late 1800s in Germany, Expressionism, focused on portraying emotional experience instead of physical reality. Probably the best-known Expressionist painting is Edvard Munch's "The Scream" (1893).

as Rene Magritte and Salvador Dali, influenced by the work of Sigmund Freud, painted images of the subconscious. Finally, the period also saw increasingly abstract and non-representational art, represented by Joan Miro and Fernand Leger.

The early twentieth century (c.1900-1945).

Building upon these dramatic artistic changes, painters in the early twentieth century explored progressively more radical approaches to art. Much of the art of this period should be seen in light of the catastrophic events of the period: World War I, the Great Depression, the rise of fascist dictatorships, and World War II ending with the nuclear attacks on Hiroshima and Nagasaki. These, along with the faster and more mechanized pace of modern life, led to a good deal of alienation and disillusionment with civilization. The giant of the age was Pablo Picasso, who went through a bewildering number of styles that especially reflected the century's rapid pace of change. One such style was Cubism, taking Cezanne's geometric approach one-step further and reducing a scene to a collage of cubes. Another approach was that of Surrealism, where artists such

Top to bottom: Picasso's *Woman with a Guitar*, Salvador Dali's *Maximum Speed of Raphael's Madonna* showing post World War II fascination with atomic energy, and Joan Miro's *Ciphers and Constellations in Love with a Woman*

Post Modern art. After World War II, the art world fragmented into a dizzying array of schools and

approaches that seemed increasingly out of touch with mainstream culture: Abstract Expressionism, Color field painting, Pop art, Op art, Hard-edge painting, Minimal art, Lyrical Abstraction, FLUXUS, Post-minimalism, and Photorealism. Largely replacing painting in popularity have been new visual media, especially film, video, and television

In recent decades a new term has come into use, postmodern, describing art considered largely contradictory to modern art in its use of such things as collages, objects of consumer or popular culture (e.g., Andy Warhol's Campbell's Soup can), words as a central artistic element and various multimedia. . By the late 1970s some critics were even speaking about the "end of painting", although some artists since the 1980s have returned to representational art, known in its modern incarnation as Figurativism.

[Back to flowchart](#)

THE REVOLUTION IN RENAISSANCE PAINTING

Introduction. Perhaps the most dramatic, or at least widely acclaimed, breakthrough in the Renaissance was in the realm of art, in particular painting. Not only did Renaissance art reflect growing concern with secular subjects, it involved new artistic tools and techniques that more accurately portrayed those subjects. Pre-eminent among those tools was the shift from tempera (egg based) paints painted on wood or as frescoes on walls to oil based paints applied to canvas.

Materials used. *Frescoes* were wall paintings applied to wet plaster that set into the wall when dry. While this did help preserve the painting, it had several drawbacks. First of all, frescoes dried quickly so an artist had to plan his work thoroughly in advance, since to change any mistakes involved redoing the whole painting. This made frescoes stiff and less spontaneous. Also, the rough surface of a plaster wall made it hard to work details, forcing the artist to use a pointed brush and even at times to stipple the surface dot by dot. To deal with these limitations, an artist would divide the wall into sections, one for each day's work. He would also do extensive preliminary drawings of the planned painting on the wall.

Tempera was the type of paint used, consisting of egg mixed with pigment. This created a light, but somewhat limited range of colors. It dried quickly, which prevented the layering of paints and the subtle shading (known as *chiaroscuro*) of a painting.

Oil based paints were developed as early as the 1100s and were first widely used in the Low Countries in the early 1400s. Since it dried slowly, oil had three major advantages over tempera. First, it could be layered, which made possible the use of *chiaroscuro* & *sfumato* (a technique giving a painting a misty, foggy, or smoky effect). Second, artists could mix colors with oils, giving them a broader and richer palette to work with than ever before. Finally, as evidenced by X-rays of paintings, artists could, and did, change mistakes, thus letting them be more spontaneous in their work.

While oil paints were widely used in the North, they did not reach Italy until about 1475. Artists in Venice were the first Italians to use oil enthusiastically, their paintings being distinguished by the rich reds they often used. From Venice, the use of oil based paints spread rapidly across Italy.

Canvas as a medium for painting had as dramatic an impact on art as did oil paints. Not having to rely on walls, especially Church walls, for a painting surface, artists could paint smaller portraits and paintings with other themes, opening up wider markets for their talents. Canvas was also more portable, so artists could work in the privacy of their own studios where they could better attract models (especially for nude paintings). These two factors, plus growing middle class patronage, led to a commercial revolution in art and the end of the dominance of the Church, kings, and nobles who previously had the money and walls artists needed. Consequently, they could now pursue a much broader range of topics for paintings.

New techniques in painting also helped transform Renaissance art. The most important of these was *linear perspective*, which allowed artists to attain three-dimensional effects on a two dimensional surface. Without it, paintings were crowded and limited in the number of people and details that could be represented. Greek and Roman paintings had achieved a high degree of perspective, but their techniques were lost during the Middle Ages. True linear perspective was first attained around 1420 in a remarkable experiment done by Filippo Brunelleschi, the same man who had designed the dome of Santa Maria del Fiore in Florence.

Brunelleschi painted Florence's Baptistery from the perspective of the facing cathedral doorway. He then drilled a hole through the vanishing point of the painting (which faced the Baptistery) and set a mirror in front of it. As someone in the cathedral doorway looked toward the Baptistery through the peephole, Brunelleschi could raise or lower the mirror so the viewer was alternately seeing the Baptistery or the reflection of the painting. Supposedly, his painting and mastery of perspective were so good, viewers could not tell the difference between the real Baptistery and the reflected painting. This dramatic demonstration, plus more secular themes, proper proportion, and attention to details, triggered a virtual revolution, not just in art, but in a whole new way of viewing the world that has become a vital part of our civilization. In the 1600s, this new perspective on the world would help lead to the Scientific Revolution.

Giotto: A new beginning

Rather than saying medieval painting was bad, it would be more accurate to say it was different. Its point of emphasis was religious, so paying undue attention to secular details

seemed unnecessary, if not a bit sacrilegious. Thus mutant animals, swastika kneecaps, and angry sock puppets, as The Tapestry of Creation from Girona, Spain in the 11th-12th centuries seemed to portray, didn't seem so out of place.

Giotto (1267-1337) served as a transition between medieval and Renaissance art. His paintings, which were usually religious, showed more realistic portrayals of humans, sometimes in an undefined spiritual space and sometimes in a more defined terrestrial location, such as his painting of St. Jerome (below). He was very popular in his own day and helped spread the new ideas and techniques in painting throughout Italy.

Giotto still had a long way to go to achieve the realism of later Renaissance paintings. Although he did a good job with rocky backgrounds and structures such as buildings and tables, his skies, were somewhat generic, while animals and especially plants were somewhat hard to identify. He still used a medieval sense of proportion, with his buildings the same size as humans, making them look like children's playhouses.

Giotto's portrayal of faces was realistic, but typically looked like they were drawn from a single model with an occasional beard thrown in

to distinguish them from one another. Finally, he seems to have suffered from what one might call "Butch Syndrome", where he portrayed babies as looking like forty-year old men who should be smoking cigars. Nevertheless, his work signaled a breakthrough in how people looked at and would portray the world around them. After Giotto there was no looking back.

How to Fresco

The *cartone*, from which we get such words as chart and cartoon, was a full-scale preliminary drawing an artist did before painting a fresco. He would then place over the appropriate part of the wall and poke pin or pencil holes around all the lines, leaving a detailed impression of the picture on the wall that he could use to guide his painting. The fresco was done in four phases.

1) Lay down a half inch layer of intonaco, a mixture of lime and sand that was permeable, absorbed colors and then locked them in. Intonaco was made by heating limestone or marble in a kiln, which produced a white powder called quicklime (calcium oxide). When soaked or slaked in water this created calcium hydroxide that was mixed with sand and applied to the wall. When the water evaporated, the calcium hydroxide reacted with carbon dioxide in the air, once again producing Calcium carbonate that hardened into stone and locked in the paint. Plasterers had to be very careful applying this mixture, because the quicklime generated so much heat that not only could it damage the painting if applied too liberally, but also the stone wall behind it.

2) Apply the cartone through spolvero, thousands of perforations with charcoal blown through them. A faster way was to put the cartone on the wall and trace it with the point of a stylus, leaving impressions in wet plaster

3) Painting a fresco (on wet plaster) so the paint would set in permanently once the plaster was dry.

4) Painting a secco, which was applying a second layer of paint to the dried plaster to add detail and shading. This had the advantage of being able to use a wider array of paints, such as ultramarine that might otherwise be damaged by the quicklime. The disadvantage, of course, was that it would deteriorate more quickly than the colors painted a fresco.

Quicklime was so corrosive, it was sprinkled on corpses to hasten their decomposition and cut the stench. This was especially used during times of epidemic when death (and stench) rates were unusually high. The need for marble and limestone to make quicklime at such times contributed heavily to the destruction of ancient monuments during the middle ages.

True colors

Many of the best colors came from Venice, which had the most access to trade with the East. Artists or even their patrons went there to fetch the needed pigments, the cost of travel offset by the lower cost in using one less middleman.

The most famous dealers in pigments in Florence were the Gesuati friars. Artists were members of the Guild of Apothecaries since they dealt with chemicals that sometimes doubled as pigments and medicines. For instance, gum tragacanth was used both as a binder and to cure coughs, hoarseness, and weals on eyelids.

There were four basic sources for pigments: minerals, earths (soils and clay), dyes (from plant and animal matter), and mixing chemicals.

Smaltino (used for the blue in sky and water) was made by pulverizing glass tinted with cobalt, which had arsenic that was also used as an insecticide. Our word smelt comes from the friars' technique of heating the cobalt to get

smaltino from it to be added to molten glass. In paintings made with smaltino, one can see grains of powdered glass under a microscope. Coarsely ground smaltino yielded dark blue. More finely ground it gave a paler blue. Coarsely ground smaltino was usually the first paint applied because it adhered better to the wetter plaster.

Many pigments came from the clays and soils in Tuscany.

- The yellowish brown soil found around the hills of Siena, if heated in furnace produced a reddish brown we still refer to as burnt sienna.
- Raw umber came from soils rich in manganese dioxide.
- Red ocher was derived from the ruddy clay dug in Tuscany. Minerals produced some of the deepest colors, but also involved laborious grinding.
- St. John's white was produced from quicklime in Florence that was slaked, and buried in a pit for several weeks, yielding a thick paste that was then exposed to the sun to cake.
- Terra Verde came from the grayish green glauconite quarried near Verona.
- Ultramarine (literally "blue that came from beyond the sea") was made with lapis coming all the way from Afghanistan. Therefore, it was the most expensive pigment used for blue, costing eight gold ducats per ounce, thirty times more expensive than azurite, the next most expensive blue.
- Indian Yellow came from feeding mangoes to cows and collecting their urine. It was then pressed into balls of pigment.
- The most lethal paint was orpiment, which contained arsenic sulphide.

For deep carmine red they used the bodies of female wingless insects that fed on prickly pear cactus. More commonly, the root of madder plants (below) was processed to get a deer red pigment.

Brushes were made from the fur of squirrels or short-tailed weasels known as ermine or stoats. However, the lime in the plaster destroyed such brushes. Therefore, Michelangelo used brushes made from hog bristles. Sometimes, he worked so frenetically that bristles were left in the fresco.

Art or porn?

Justifying nude paintings and statues was tricky business back when the Church was closely watching. The most common tactic was to label any nude figure as a character from Greek and Roman mythology or history. Usually, in the case of female nudes, this was the goddess Venus. This was pretty much how the game was played until the 1800s.

For example, in 1863, there were two female nudes displayed at a show in Paris, one entitled *The Birth of Venus* (left), and the other a common woman's name, Olympia. Even though the painting of Venus was every bit as provocative as the Olympia, it was the hit of the show, while the Olympia was the scandal of Paris, prompting rumors that viewing it would cause pregnant women to miscarry and men to go mad and bite people in the streets.

A New Perspective

Around 1413, Filippo Brunelleschi made a painting of Florence's Baptistery from the perspective of the facing cathedral doorway. He then drilled a hole through the vanishing point of the painting (which faced the Baptistery) and set a mirror in front of it. As someone in the cathedral doorway looked toward the Baptistery through the peephole, Brunelleschi could raise or lower the mirror so the viewer was alternately seeing the Baptistery or the reflection of the painting. Supposedly, Brunelleschi's mastery of perspective were so good, viewers could not tell the difference between the real Baptistery and its reflected painting.

Perspective had been born. Or more likely, reborn, since the Greeks and Romans seem to have mastered it too.

Although Brunelleschi's painting has not survived, his technique of creating the illusion of a three-dimensional image on a two-dimensional surface has.

Masaccio (1401-28), an artistic genius who unfortunately died at a young age, is credited with first using Brunelleschi's linear perspective in the painting *Trinity with the Virgin* (1425) along with pioneering the use of one light source to illuminate a painting.

Massaccio was known as Sloppy Tom, reflecting an apparent trend in Renaissance artists either to be naturally ugly or take little care in how they looked. Similarly, the popular nickname for famous medieval artist, Cimabue, meant "Oxhead."

The first "super-model"

Artists often like to use the same model in many or most of their paintings. Such was the case with Boticelli and a young woman named Simonetta Vespucci, who was considered the most beautiful woman in Florence. Boticelli painted her numerous times: as Venus, as the goddess Flora in *Spring Allegory*, as the Virgin Mary, and as Athena, along with at least two portraits. In fact, she was supposedly the only woman he ever painted. When she died from tuberculosis at age 22 all Florence mourned her passing. Even though she was married, Boticelli, along with most of the men in Florence, was in love with her, and he had himself buried at the feet of her grave when he died.

According to legend, Giuliano de Medici, Lorenzo's brother, had a vampire-hunter catch a vampire who turned Simonetta into a vampire to save her from dying. However, when she found Giuliano more appealing as a meal than a lover, he had her cornered in Florence's bell-tower, from which she jumped to her death.

Savonarola and the Bonfire of the Vanities

The French invasion of Italy in 1494 triggered a powerful religious reaction against Renaissance secularism. Its leader, the monk

Savonarola, imposed a harsh reign on Florence, burning many of its luxuries, including a number of paintings, in what became known as the Bonfire of the Vanities.

Savonarola was overthrown and executed in 1498, but not before he had profoundly influenced the work of artists such as Botticelli, who after that only painted religious themes, such as his Pieta.

Mona Lisa (1503-6) is probably the portrait of a Florentine merchant's wife, this painting shows Leonardo's genius in several ways: the great eye contact, the more relaxed 3/4 pose, the use of sfumato (layered thin translucent glazes of paint to give the impression of haze), and the busy background of jagged peaks, winding roads, and receding waters to give tension to this otherwise placid painting.

Leonardo used musicians and jesters to keep his subject amused through the sitting. He even lived in a hospital and dissected over 30 cadavers in his research to render the hands flawlessly.

People viewing this painting in the Louvre in Paris are typically struck by its small size, given how large it looms in the history of art. Most likely, the merchant who commissioned the painting could only afford a small portrait. In fact, for whatever reason (lack of payment?) Leonardo kept the painting for himself and later sold it to the French king, Francis I.

The Last Supper (1495-8) depicts the dramatic moment when Christ reveals that one of his disciples will betray him. Much of its genius is the depiction of the wide array of emotional reactions by the disciples: ranging from shock

and disbelief to dismay and feigned innocence (e.g., Judas, who is the fourth from the left, holding a bag of what is presumably the thirty pieces of silver for which he betrayed Jesus). Yes, all twelve disciples are there, the womanish figure sixth from the right apparently being the apostle John rather than Mary Magdalene, a blow to the theory of that being Jesus' wife.

The painting's effect comes from it being painted at the end of a long dining hall, to add to the appearance of depth. This also gives it a masterful effect of single point perspective with all the lines of the painting and room converging over Jesus.

Its poor condition is largely due to Leonardo experimenting with painting on dry plaster, as opposed to fresco. His experiment did provide him a wider palette of colors, but paint started chipping off almost immediately. They've been trying to restore it almost continuously ever since.

Two other bits of trivia about this painting. Because of Leonardo's irregular work habits, the prior of the abbey constantly hassled him to finish the painting. To the prior's shock and dismay, when it was finished after three years, he saw that his face had been used to depict Judas.

Leonardo did paint Jesus' feet, but around 1650 someone decided to put a door into that part of the wall. Luckily it wasn't a window.

Davids. Another theme for bronze statues that both Donatello (c.1440) and Verrocchio (c.1475) tackled was that of the young David after slaying Goliath. Both statues used the Greeks' more natural pose known as *contrapposto*, showing a subject's weight shifted more to one side than the other. However, Donatello really pushed the limits in

emulating the classical Greeks by portraying David in the nude. While Verrocchio's statue was intended for public display, Donatello's nude portrayal was considered appropriate only for private viewing.

Twenty-five years later (1501-4), Michelangelo would show David both in the nude and as a full grown man, indicative of the more self-assured spirit of the High Renaissance after 1500.

Bronze statues

Casting in bronze, especially for large equestrian statues, was an especially delicate operation. First a full-size model of the statue would be fashioned from clay mixed with cow dung and charred ox horn, then covered with a layer of wax, and another thin layer of clay with holes left in the top and bottom. The whole thing would be suspended over a fire so the wax would melt and run out through the holes in the bottom, which would then be plugged up. Then molten bronze would be poured into the hole or holes in the top. Once the bronze had cooled and solidified, the outer layer of clay would be broken off to reveal the bronze statue.

The main hazard of such an operation was uneven cooling of the bronze that could cause it to contract unevenly and crack. Before casting a bronze statue, Michelangelo, would even have a special mass in the hope of ensuring everything would go well. He should have prayed for their long-term survival, since two works he successfully completed, a 14-foot bronze statue of Pope Julius II and a 4-foot statue of David were both later melted down for the bronze to make cannons.

In fact a major hazard for bronze statues was warlike rulers in search of the metal for casting cannons. There's no telling how many statues ended up on the battlefields of Europe mowing down thousands of soldiers, most of whom probably had no appreciation for art

anyway. One strategy to save a statue from such a fate was to cast it from as thin a layer of bronze as possible so it wouldn't be worth the ruler's time to melt it down. Using less bronze was also cheaper, but it also made statues more fragile.

Bronze equestrian statues were a Roman tradition that Renaissance artists were eager to revive. Done in 1453, Donatello's statue of the condottiere, Erasmo da Narni, (AKA Gattamelata, meaning honeyed cat), was the first equestrian statue cast since Roman times. It was 25 years before Verrocchio successfully completed the next such statue, that of another condottiere, Bartolomeo Colleoni (1479-83), who served Venice.

Michelangelo

Michelangelo (1475-1564) did more than anyone to elevate the status of the artist. He believed creativity was divinely inspired and that sculpture was the highest art form. His wet nurse's husband was a stonecutter, which may be where he got his fascination for sculpture, despite his father's strong approval.

While early Renaissance painting was beautiful; Michelangelo's art moved it into a new phase, often referred to as the High Renaissance. Instead of being delicate and pretty, his art was vast, powerful, rugged, and even terrifying, such as his statue of Moses, which Norman Rockwell paid a tribute to with his wartime poster of Rosie the Riveter.

Like many artists, Michelangelo was a solitary character, usually dirty from his work, and unattractive, especially after his nose was broken in a brawl with another artist. He did a particularly unappealing self-portrait in The Last Judgment, portraying himself as the sagging flayed skin of St. Bartholomew. He could also have a mean sense of humor. Once, when asked why an ox in another artist's painting was its most convincing element, he remarked, "Every painter does a good self portrait". Despite his cantankerous personality,

he was typically referred to as the Divine Michelangelo.

Not surprisingly, Michelangelo's arrogance also led to a stormy relationship with his patrons. It didn't help when they were also obnoxious or small-minded, such as the son of Lorenzo de Medici who made him use his talents to sculpt a snowman. Popes constantly interrupted his work for other projects, leaving many others unfinished. For example, Julius II commissioned Michelangelo to create 40 lifelike statues and a ten-foot tall one of the pope for his tomb as the centerpiece of St. Peter's Basilica. Despite 40 years of constant interruptions and whittling down the scale of the project, Michelangelo referred to it as the "tragedy of the tomb".

Michelangelo was so skilled a sculptor that he never had to add pieces of marble to cover mistakes. His first work of renown, the *Pieta* (1499), now residing in St. Peter's Basilica, captures the pathos of any mother who has lost a son. Upon hearing that one viewer attributed it to a more experienced sculptor, the artist carved his signature on the ribbon across the Virgin's breast, making this his only signed work.

The Sistine Chapel

The Sistine Chapel was Michelangelo's most famous and ambitious project. Built by pope Sixtus IV, its dimensions were meant to match those of Solomon's Temple in Jerusalem (130' X 43' X 65'). It was used for papal elections as well as a fortress, with 10' thick walls, arrow loops, walkways for guards, and barracks, which also made it useful as a prison later on.

Other famous artists had already adorned the walls with frescoes. In 1480, after a war with the Papacy, Lorenzo the Magnificent had sent several artists to fresco its walls: Perugino ("Christ Giving the Keys of Heaven to St. Peter"), Botticelli, and Ghirlandaio (Michelangelo's future mentor whose ambition had been to fresco the entire five-mile circumference of Florence's fortifications). Therefore, Pope Julius II only wanted the ceiling decorated with a few vines on a blue background.

Instead Michelangelo gave him the book of Genesis from Creation to the Great Flood in a fresco nearly half the length of a football field and covering 10,000 square feet with 340 larger-than-life figures. Complicating the task was the curved ceiling divided by cross vaults and a leaky roof that kept the plaster from drying properly.

Despite his supposed disdain for painting compared to sculpture (aggravated by the fact that ceiling paintings were usually delegated to minor artists since they were harder to see), the Sistine Chapel ceiling was a product of his full imagination depicting muscular nudes with twisted torsos and expressive relief-like qualities in their faces. Even though more women than usual were represented, Michelangelo only used male models, which explains why his women look so muscular.

Michelangelo completed the entire work in just 4 years, working with almost no help from a 60-foot scaffold, either lying on his back or standing with his head crooked backward. As a result of working in these conditions, he suffered serious eyestrain, claiming he could only read at arm's length holding a book above his head, the position in which he had painted the Sistine ceiling.

According to legend, Michelangelo wouldn't even let Pope Julius see the painting until the first half was completed. Therefore, Julius, dying to take a peek, bribed someone to let him in one night. Michelangelo, having sniffed out this plot, waited in ambush to drive out Julius by pelting him with planks. He then fled to Florence until the pope cooled down.

In fact, Julius gave Michelangelo a lot of freedom in how he painted his ceiling, and was exceedingly pleased when the first half of the ceiling was unveiled and he saw this powerful new approach to art.

Nudity in art. One issue that shocked many contemporaries was the portrayal of nudity, of which there was plenty, in Michelangelo's art.

In the middle ages, nudity was associated with sin and any nudes portrayed were usually shown in Hell. Even Donatello's nude statue of David (c.1440) was kept from public view and confined to private viewing. However, by the late 1400s drawing from nude models was a standard part of an artist's training, so the issue was bound to surface, and Michelangelo was the sort of person to meet it head on and pave the way for future artists.

Not that it was easy for Michelangelo. When he completed his epic nude statue of David, the Florentine government insisted on covering certain strategic parts with a garland of 28 fig leaves. The only thing that kept pope Hadrian VI from tearing down the Sistine chapel's ceiling frescoes was his untimely (or timely, depending on how you look at it) death. Michelangelo's fresco of the Last Judgment on the far wall of the Sistine Chapel wasn't so lucky. A later pope had loincloths strategically painted on it by an artist who became known as Big Underpants Man. Even in the late twentieth century when Florence offered the city of Jerusalem a copy of Michelangelo's David as a gift to celebrate the 3000th anniversary of its founding, it was only accepted after being fitted with underpants.

Helping his cause was the discovery in 1506 of the Hellenistic Greek statue of Laocoon that was done in the nude. Such a discovery was a big event then, with cheering crowds lining the roads and tossing flowers as it was transported to the Vatican. Every classical nude discovered just added further respectability to the genre by being associated with the Greek and Roman civilizations.

Some random fact about the Sistine Chapel ceiling fresco:

- The forbidden fruit Adam reaches for is not an apple, but a fig, which was a symbol of lust, thus explaining the use of fig leaves to cover certain parts of paintings.
- Portraying God in human form and flying through the air was a radical new approach. Medieval paintings would just show a giant hand reaching down from the sky. Even more

confusing may have been portraying God as an older man with flowing beard, a convention Michelangelo adopted from classical statues of the Roman god Jupiter. As a result, it took people some time to catch on to the fact that the old man reaching his finger toward Adam represented God. In fact many thought God's extended finger was a gesture of scolding, not imparting the spark of life into Adam.

- Speaking of figs and fingers, the barely perceptible small child next to the Cumaean Sibyl is making an obscene gesture, known as “making a fig” by sticking his thumb between his first two fingers. Luckily, at least for Michelangelo, the gesture is too small to be seen from floor level.

The Last Judgment was Michelangelo's other contribution to the Sistine Chapel, filling an entire wall with his terrifying portrayal of the title subject. Done 29 years after the Sistine ceiling, it is a much gloomier painting, with nearly 400 figures, most of them in contorted shapes as they tumble into Hell or struggle to escape. It is said that when Pope Paul III first viewed it, he fell to his knees saying, “Lord hold my sins not against me.”

Restoration of all the chapel's frescoes (including those done by Ghirlandaio, Perugino, Botticelli, and Raphael) took place between

1980 and 1999. There were three types of things to repair: cracks and salt damage caused by water seeping from above and settling of the building, candle smoke and soot damage from below, and removal of linseed or walnut oil from previous restorations that made any crystalline damage transparent and didn't damage the colors, but left a transparent film. In fact, this transparent film had helped protect the frescoes from exhaust and pollution coming in through the windows lining the upper tier of the chapel. Thanks to the thin layer of paint Michelangelo used, the chemicals had largely seeped through the fresco without doing any damage.

Most of this was carefully washed away without having to fill in gaps or cracks with new paint. After the restoration, the windows were permanently closed and a sophisticated air conditioning system installed to protect the frescoes from the heat, humidity, dust, and bacteria brought in by the huge crowds of tourists.

There has been plenty of criticism of the restoration, much of it revolving around the restorers' conclusion that Michelangelo painted only on wet plaster (*buon fresco*) and never came back to add details or shading to the work on dry plaster (*a secco*). As a result, they stripped everything down to the plaster on the assumption it was all dirt or chemicals added by previous restorers. Critics claim he did work *a secco* on parts of the ceiling, especially doing shading, and thus the recent restoration has destroyed or damaged much of his original work.

Rafael (1483-1520) was one of the most popular artists of his day. Unlike many disagreeable and eccentric artists, such as Donatello and Michelangelo, Rafael seems to have had a pleasant personality. He also seems to be one of the few artists who were good-looking and well groomed. Renaissance artists, such as Cimabue ("Ox head"), Masaccio ("Sloppy Tom"), and Michelangelo were better known for their unkempt and ugly appearances.

Therefore, when Rafael died at the young age of 37, he was greatly mourned.

One of his most famous paintings was *The School of Athens* (1510-11). This is a virtual greatest hits of Greek philosophers spanning several centuries. In the middle are Plato (pointing up to the perfect unchanging world of Being above) and Aristotle (pointing down to the earth where real knowledge can be gained). Shown in the pose of *The Thinker* in the foreground is Heracleitus, which is reputedly a portrait of Michelangelo.

Landscapes

Landscapes at this time were not considered worthy topics for paintings. Michelangelo among other artists usually consigned such background details to apprentices. However, Giorgione's *The Tempest* (1506-8) may be among the earliest examples of an artist bucking this tide.

Ranked by a poll of art historians as the third best painting ever, there is no consensus on its meaning. In the foreground is a woman nursing a child and a man looking in her direction. One idea is it represents the expulsion of Adam and Eve from Paradise, but X-rays show the artist originally had a woman where the man is standing. It could be Giorgione was mainly interested in doing a landscape. However, since that was considered too trivial a topic for a painting, he may have thrown some people into the picture to satisfy potential critics.

A number of later artists may have followed this strategy of justifying their landscapes by putting in a few people and entitling the paintings after them or events associated with them. Not until the 1600s in the Dutch Republic would the landscape and still life emerge as legitimate topics for painters.

THE NORTHERN RENAISSANCE (c.1500-1600)

Introduction. There are several reasons why the Renaissance came later to Northern Europe. First, it was further removed from the centers of trade and culture in the Mediterranean. As a result, towns, trade, and the more progressive ideas that tend to come with wealth developed more slowly in the North. Along these lines, the greater influence of feudalism and the Church kept the political, social, and intellectual institutions much more medieval and backward. This in turn provided more resistance to the humanistic ideas developing in Italy.

However, the revival of towns and trade in the North combined with other factors in three ways to bring the Renaissance to Northern Europe. First of all, the urban revival in the North along with the Portuguese and Spanish overseas colonies created the financial resources needed to patronize the arts. Secondly, growing trade in the North, combined with the French invasion of Italy in 1494 and the ability of the printing press to spread ideas quickly and accurately, led to growing contact with the ideas of the Italian Renaissance. Finally, the rise of towns together with the rising national monarchies in France, England, Spain, and Portugal led to the decline of the feudal nobility and medieval Church. This created less resistance to the new ideas from the Renaissance. All these factors came together to produce the Northern Renaissance (c.1500-1600).

Bruges

Much like Florence in Italy, the Flemish city of Bruges was both the leading banking and cultural center in northern Europe in the 1400s. As in Italy, activities in North European cities usually concentrated around the town squares. Besides a market place, there would be the town hall, a symbol of civic pride nearly equal in importance to the town's cathedral.

The Northern Renaissance was not a mere copy-cat of the Italian Renaissance. The movements in Italy and the North differed in two ways. First of all, the Church's influence, despite being shaken by recent corruption and scandals, still was strong enough to make the Northern Renaissance more religious in nature. Second, the rising power of the national monarchies made the Northern Renaissance more nationalistic in character.

Reconciling religion and the Renaissance. The more intense religious feelings prevailing in Northern Europe posed a difficult question: could a humanist education based on classical culture be reconciled with Christianity? The answer humanists came up with was yes. This was largely thanks to the greatest humanist of the age: Erasmus of Rotterdam (1466-1536). Called the "Prince of Humanists" and the "scholar of Europe", Erasmus dominated Northern Europe's culture in a way few, if any, other scholars have before or since his time. So great was his reputation that kings and princes from all over Europe competed for his services at their courts. Erasmus popularized classical civilization with his *Adages*, a collection of ancient proverbs with his own commentaries. His *Praise of Folly* satirized the follies and vices of the day, in particular those of the Church, while further popularizing humanism. Erasmus was still a pious Christian who pushed the idea that it was one's inner spirit, not outward shows of piety through empty rituals, that really mattered. However, he saw no contradictions between Christianity and ancient cultures. He underscored this attitude by referring to the ancient Greek philosopher, Socrates, as "Saint Socrates".

Among the stock characters criticized in Erasmus' *Praise of Folly* were Franciscan friars who were no longer the austere mendicants of St Francis' day. Our picture of Robin Hood's comrade, Friar Tuck, as a jolly hard drinking and hard-fighting man largely come from Erasmus' stereotype. However, contemporary stereotypes were often much more critical, seeing them as fat, bloated, lazy, and corrupt.

***The Thousand Adages* was a collection of wise sayings by the ancients compiled by Erasmus to show that they had wisdom and moral values compatible with Christianity, thus helping justify humanistic studies. The first edition published in 1500 had about 800 such proverbs. His final edition before he died had over 3,000, while he had collected 4,658 of these sayings. Many of these, or variations on them, have made their way into our own common wisdom:**

- **Like teaching an old man a new language (Can't teach an old dog new tricks)**
- **A necessary evil**
- **To squeeze water out of a stone**
- **To leave no stone unturned**

- **God helps those who help themselves**
- **The grass is greener over the fence**
- **The cart before the horse**
- **To sleep on it**
- **To break the ice**
- **Ship-shape**
- **To look a gift horse in the mouth**
- **Like father, like son**

Other humanists in the North would pick up this banner. In England, Thomas More brilliantly defended studying classical Greek and Roman culture by saying their knowledge and the study of the natural world could serve as a ladder to the study of the supernatural. Besides, he pointed out, even if theology were the sole aim of one's education, how could one truly know the scriptures without knowing Greek and Hebrew, their original languages? It was in this spirit that the French humanist, Lefebvre d'Etaples, laid five different Hebrew versions of the Book of Psalms side by side in order to get a better translation than the one in the Latin Vulgate Bible. Even in Spain, the most staunchly Christian country in Europe, Cardinal Ximenes, who served as virtual prime minister for Ferdinand and Isabella, set up a university at Alcala with a very humanist curriculum. Its purpose was to use humanism to provide better understanding of Christianity. The major accomplishment of Erasmus and the Northern humanists was that they successfully defended the study of the classics and a more secular education as a ladder to better understanding of Christianity. This in turn paved the way for using a secular education for more secular purposes and that would revolutionize Western Civilization.

Art also reflected the more religious nature of the Northern Renaissance. Secular and even mythological themes would appear, but with less frequency than in Italy. This intense religious passion is especially reflected in the work of the Spanish artist, El Greco. Technically, art in the North lagged behind Italy throughout the 1400's, especially in its use of perspective and proportion. The key turning point came when the German artist, Albrecht Durer, traveled to Italy in 1494 to study its art. Durer was heavily influenced by the Italians and the ancient writer, Vitruvius, in their efforts to find the mathematical proportions for portraying the perfect figure. Among other things, this shows a growing fusion of art and science that anticipated the scientific revolution that would sweep Europe two centuries later. Other northern artists followed Durer, and from this time one sees a more realistic art in the North, which approached the standards of the Italian artists.

Art in Northern Europe was on the whole more medieval (i.e., religious) in theme than its Italian counterparts, but leapt ahead of Italy in a couple ways. One of these was the invention of oil paints. Hubert Van Eyck was popularly credited with this innovation in the early 1400s. As a result, his right arm was preserved as a holy relic.

Since oil dried more slowly than tempera, colors could be mixed better, thus giving a deeper and broader range of colors, as seen in Hans Memling's painting of the Madonna and Child

Artists in the North also painted everyday objects with more precise detail. Part of this was the result of the greater possibilities oil paints offered. Part of it also came from the fact that, in contrast to the Italians' reverence for and emulation of classical idealism and the idea of elevating the status of humans, Northern artists did little to cover up human shortcomings, since God's glory and fear of eternal damnation was more their focus. Therefore, their portraits typically had a stark realism about them, while other paintings were more likely to be concerned with the terrors of Hell, as in Jan Van Eyck's painting of the Last Judgment.

The emerging national cultures in the Northern Renaissance. The other major feature of the Northern Renaissance was the national character of the cultures that were evolving along with their respective nation-states in Europe. The literature of the age especially showed this in the tendency of authors to write in the vernacular to reflect their respective national cultures. In Spain the great literary genius was Cervantes, whose *Don Quixote* showed the changing values of the age by satirizing the medieval values of the nobility. Probably the greatest literary genius of the age was William Shakespeare, whose work reflects heavy influence from the Italian Renaissance. Many of his plays have Greek and Roman themes, sometimes copying the plot lines from classical plays (e.g.--*Comedy of Errors*) or take place in Italy (e.g.--*Romeo and Juliet*). However, many of Shakespeare's other plays take place in England and reflect the fact that the various nations in Northern Europe were

defining their own unique cultures apart from Italian and classical influence.

Results of the Northern Renaissance. Ironically, one could say the most important result of the Northern Renaissance was a religious revolution. This was the result of a several factors: anger at the church's corruption, awareness of which was magnified by the printing press, the rising power of kings at the expense of the popes, and the fusion of Renaissance ideas from Italy with the still intense religious fervor and emerging national cultures of the North. The dynamic combination of these factors would lead to the Protestant Reformation that, in turn, would branch off in three lines of development.

First, the Protestant Reformation would open the way for new ideas about money and the middle class, and that would help lead to the triumph of capitalism in Northern Europe. Secondly, the Protestant Reformation would play a vital role by shattering the Church's monopoly on religious truth, breaking its iron grip on scientific thinking, and paving the way for the Scientific Revolution of the late 1600's and 1700's.

Third, the growing power of kings in Northern Europe, combined with Renaissance learning and local anger at Church abuses, helped pave the way for more secular theories about the state. Among other things, this would lead to the theoretical backing for the democratic revolutions that would eventually overthrow the very monarchies that the Renaissance had earlier helped build.

The Arnolfini Wedding Portrait and the Camera Obscura Controversy

Jan van Eyck (1390-1441) took oil painting to a peak of realism, even depicting beard stubble with amazing microscopic precision. His painting, Man in a Red Turban, which is possibly a self-portrait, is the first known painting where the subject looked at the spectator.

The Arnolfini Wedding Portrait is one of van Eyck's most famous and remarkable paintings. Almost every object in it symbolized the painting's theme of sanctity of marriage:

- **The dog represents fidelity, although in other contexts it can represent lust.**
- **The cast off shoes indicate they are standing on holy ground.**
- **The bed and picture of St. Margaret on the back of the chair represent childbirth, the purpose of marriage.**
- **Van Eyck's signature and reflection in the mirror show he was a witness to the wedding.**
- **The bride's apparent pregnancy is probably more symbolic of the hope of children. The prevailing fashion in dresses of the time seemed to emphasize this. So did the normal portrayal of women's abdomens. Since most such pictures of women showed them burning in Hell, it seems unlikely they were supposed to be pregnant, as this would indicate God was condemning unborn babies to eternal damnation as well. In fact, the Arnolfini marriage remained childless.**

Even more striking about this painting are the technical details, in particular the chandelier and reflection in the convex mirror showing the artist. There has been speculation that van Eyck and other North European artists used a device known as the *camera obscura* to capture this level of detail.

In the camera obscura, a convex mirror inside a box reflects an image from outside against

the opposite wall. Although the image is backwards and upside down, it can still be traced precisely by an artist. Some art historians think this is how Flemish artists attained such photographic realism in some of their paintings. One bit of evidence supposedly supporting this theory is the disproportionate number of left-handed people in their paintings, suggesting they were traced from the backward images reflected by the mirror.

However, there are several problems with this theory, in particular with the mirror:

- 1) Polished metal cannot project an image with the resolution required for such a detailed painting. Only a glass mirror can.
- 2) Measurements of the convex mirror in the painting show that the a concave mirror used for projecting the image for this painting would require a focal length of 61 cm. The diameter of the glass sphere from which such a mirror was made had to be four times that size. That would require a glass sphere 2.4 meters in diameter, far beyond the capability of craftsmen then.
- 3) There is no evidence that craftsmen of this time could make concave glass mirrors by reversing a glass sphere, silvering it, and sealing it with hot tar or pitch.
- 4) Other calculations and experiments indicate that the lighting in the room would not have been bright enough to project a traceable image.
- 5) Infrared reflectography shows that Van Eyck did preliminary drawing and changes in oil paint, not in pencil, which would not be consistent with tracing a projected image.

Hieronymus Bosch (1450-1516)

Hieronymus Bosch's surreal paintings have been subject to various interpretations from one era to the next. They were especially popular with the counter-culture in the 1960s since they seemed to be inspired by some sort of hallucinogenic drugs. Maybe there was something in the bread, like a bread mold

known as ergot, which does cause hallucinations.

But Bosch's message, taken in the context of his own times, was fairly consistent and clear to his contemporaries: shape up or go to Hell. His art also highlights a major difference between the art of Italy and the rest of Western Europe: a greater obsession with and fear of Hell, demons, and the Judgment Day.

Along those lines Bosch and other artists of the time also liked to depict human folly and its rewards, as seen in paintings such as *The Stone Operation* and *Ship of Fools*.

One intriguing image from Bosch's *The Last Judgment* is the panel known as "Ascent of the Blessed", which is reminiscent of how people describe near-death experiences.

Pieter Brueghel the Elder (1525-69)

Brueghel was another Flemish artist who was heavily influenced by Bosch's apocalyptic visions along with his pessimism and satiric approach to human nature. One genre that especially distinguishes Brueghel's work is his depiction of scenes of peasant life, something quite rare at this time and thus representing an invaluable record of the lives of the common people. Such works as *Hunters in the*

Snow (above), *The Numbering at Bethlehem*, *Children's Games*, and *Peasants Attacked by Robbers* give us insights into daily life that no contemporary writers do. For example, his incredible eye for details even show us winter sports such as sledding and skating (using skates made from horses' shins).

Oftentimes, these paintings, such as *The Blind Leading the Blind*, *The Beggars*, and *the Land of Cockayne*, also served the purpose of moralizing about human nature, showing people with exaggerated and even bestial expressions to further make his point. This might have been less acceptable if he had shown the upper classes instead. Or maybe he used such moralizing to justify portraying commoners.

However, the date (1566) and place of this painting are important, because, the Spanish Netherlands were then on the verge of rebellion against Spanish repression. Thus the painting, with contemporary figures and setting, also serves as anti-Spanish propaganda. But Bruegel, if ever questioned by the authorities, would never admit that was its real message.

Bruegel especially shows Bosch's influence in his paintings with apocalyptic themes, such as *The Triumph of Death*, *Fall of the Rebel Angels*, and *Mad Meg* (below), which are jam packed with all sorts of terrifying and bizarre creatures and other frightening details meant to scare us straight.

El Greco (1541-1614) is considered the epitome of capturing the spirit of both the Spanish Renaissance and Catholic Reformation, even though, as his name indicates, he wasn't originally from or raised in Spain. He was born Domenikos Theotocopoulos on Crete where he learned the flat, highly patterned Byzantine style of painting.

Sometimes there's more to a painting than meets the eye. For example, Bruegel's *Massacre of the Innocents* operates on two levels. On one level, it depicts the story of King Herod's attempt to kill the baby Jesus by killing all the newborn boys in the kingdom.

He then went to Venice where he learned Titian's vivid color & Tintoretto's lighting. At age 35, he migrated to Toledo, Spain during the religious frenzy of the Catholic Reformation and Inquisition, which influenced his surreal and emotionally intense paintings with their distorted figures and swirling movement.

El Greco was supremely self-confident, even declaring Michelangelo couldn't paint and offering to revamp the "Last Judgment". He detested walking in daylight, claiming it "blinds the light within," which influenced his use of harsh colors: strong pink, acid green, and bright yellow as in *The Holy Trinity* below.

The elongated figures in El Greco's paintings inspired a fashion for elongated fingers among the women at the Spanish court. Supposedly at night they would hang their fingers from the bedposts to stretch them out.

A poll among art historians rated this as the 6th greatest painting of all time. The rest of the list is as follows:

- 1) Velazquez, "Las Meninas"
- 2) Vermeer, "View of Delft"
- 3) Giorgione, "The Tempest"
- 4) Botticelli, "La Primavera"
- 5) Francesca, "The Resurrection"
- 6) El Greco, "Burial of Count Orgaz"
- 7) Giotto, "The Lamentation"
- 8) Grunewald, "Isenheim Altarpiece"
- 9) Picasso, "Guernica"
- 10) Rembrandt, "The Return of the Prodigal Son"

Shakespeare and the English language

No one person has had a greater impact on the English language than Shakespeare, adding all sorts of words and phrases to our vocabulary. Some were derived from Latin roots. Others were probably already in common use, and he was the first to write them down. Following are some of the 1500 words he added to the language: aerial, amazement, approve, auspicious, ban, bump, cage, countless, courtship, critical, dishearten, dislocate, dwindle, exposure, film, fond, frugal, general, generous, gnarled, impartial, infinite, jovial, kissing, knave, lapse, laughable, lonely, loon, majestic, make, misplaced, monumental, nobility, numb, obscene, pious,

premeditated, radiance, submerge, and undress.

Shakespearean phrases:

- The undiscovered country
- Brave new world
- The milk of human kindness
- Something's rotten in Denmark
- The game is up
- Dead as a doornail
- Without rhyme or reason
- Too much of a good thing
- Foregone conclusion
- Down the primrose path
- Vanish into thin air
- One fell swoop

FC.78A THE EVOLUTION OF MODERN THEATER

While we look back upon the ancient Greeks as the beginnings of modern theater, their influence has taken a somewhat indirect route. The Romans during the late Republic and Early Empire (c.100 B.C.E.-200 C.E.) did indeed carry on the traditions of Greek theater. In the late Republic, plays of Greek New Comedy, especially those by Menander, were translated and imitated by the playwrights Plautus and Terence. Similarly, Seneca (c.4 B.C.E. – 65 C.E.) continued Greek tragic forms during the Pax Romana. However, since Roman drama wasn't connected to religious rites like Greek drama was to the god Dionysus, it grew increasingly sensational over time in order to attract audiences, much like many Hollywood movies today. Therefore, when Christianity became the state religion, it should come as no surprise that the Church outlawed drama.

After the fall of the Roman Empire in the West (c.500CE), Latin became increasingly unintelligible to most people, making the Catholic mass done in Latin almost equally unintelligible to the common people. Therefore, liturgical dramas were created that would act out scenes during the mass so that people could gain some understanding of their religion.

With the rise of towns in the High and Late Middle Ages (c.1100-1450) came an increasingly secular outlook with corresponding impact on drama, especially as it moved out into the streets. For one thing, there were numerous traveling shows with such things as jugglers and trained animals, whose repertoire might also contain short skits. At the same time, guilds, as part of their civic and religious duty, would often put on religious miracle plays, usually in mime, to educate the common people about their religion. Over time, the combined influences of the guilds' miracle plays and the traveling shows, gave rise to morality plays with dialogue and sometimes secular themes, although still considered appropriate by the Church. Eventually, these developed into plays known as interludes with increasingly secular and even comedic themes. By the time of Henry VIII, these interludes had lower class characters and ludicrous and, at times, comedic plots. From the Church's

point of view, it seemed that pagan vulgarity had revived in full force.

However, it was the Italian Renaissance and the rediscovery of Seneca and other ancient dramas that helped bring theater back to the level of high art after 1580 during the reign of Elizabeth I of England (1558-1603). Elizabethan drama was characterized by several features that have, to one extent or another, remained with theater ever since. One was replacing inn courtyards as makeshift theaters with the construction of permanent playhouses with stages and, later, curtains. Over the years, this would allow the evolution of increasingly elaborate scenery and special effects that required permanent mechanical devices set up backstage and out of sight. Elizabethan drama was also written in blank instead of rhymed verse, eventually leading to the prose used in modern plays. The plots of these plays were secular, being based on plays by Seneca and Menander, ancient Greek and Roman history and literature*, medieval literature, or more recent English history. Finally, whereas previously plays were often private affairs for the entertainment of the rich and powerful, Elizabethan plays were put on as public performances open to all classes, although seating was segregated between the balcony seats for the rich and the ground for the common folk.

During the 1600s, England would go through a period of civil wars and military dictatorship under the Puritan, Oliver Cromwell, who would shut down the theaters, deeming them as sinful places. However, with the restoration of the Monarchy under Charles II in 1661, drama would make a major comeback in what is known as Restoration drama, which first pushed tragedy, although later much of it would be lighter in tone, much like the New Comedy of Menander and our own sit-coms. However, it was here to stay, influencing the dramatic arts to the present day.

*E.g., "Romeo and Juliet", which was based on "Pyramus and Thisbe", one of Ovid's poems in his *Metamorphoses*, which itself was inspired by a Mesopotamian legend).

The evolution of the playhouse
Inn-yards, as they were called, could hold around 500 people gathered around a makeshift stage. Richer people could pay for

places in the surrounding balconies. This would also protect them from pickpockets and fights that often took place in the overcrowded conditions below.

Replacing the inn-yard, starting in 1576, was the Elizabethan amphitheater. Built in the round like Greek and Roman amphitheaters and holding up to 3,000 people in ever higher (and more expensive) balconies, these amphitheaters gave acting troupes more permanent facilities so they didn't have to travel as much or spend time and effort building and taking down the stages. Being modeled on ancient Greek and Roman theaters, they may also have given actors and acting a bit more status and respectability.

Since inn-yards and amphitheaters were open air, performances were limited to daytime and good weather during the warmer months of the year. As a result, promoters started building fully enclosed playhouses that were open year round and could even hold performances at night. Since candles typically would not last an entire performance, intermissions were introduced to allow a change of lighting.

Playhouses allowed more elaborate and permanent scenery to be developed, since it was no longer exposed to the elements. Similarly, large inventories of costumes could be kept for multiple plays, adding an element of realism and interest especially to historical plays. Even more importantly, the better acoustics from being inside shifted the emphasis from special effects to dialogue, since actors could now be heard. This, in turn, added to the seriousness of drama as an art form. On the downside, special effects, in particular fireworks, could not be used due to the risk of burning down the playhouse. Another advantage of playhouses was that everyone got seats, although capacity was once again limited to around 500 people. This also added to expenses, which added to the price of tickets.

Actresses, Makeup, and Sumptuary Laws

There were no actresses during Elizabeth's reign. Much like Greek theater, boys would play women's roles, at least until their voices changed, disguised in wigs and female attire. They also used makeup, which unfortunately was lead based and probably killed or permanently sickened many of those who wore it, including Queen Elizabeth herself. Later, women would be allowed to act, but acting was seen as especially disreputable for women, being almost on a par with prostitution. Given the low pay actresses received, the two careers might go hand in hand. The more famous actresses might even become mistresses of the wealthy and powerful. Most notable in this respect was Nell Gwynn, who became the mistress of Charles II, or as she called him, "my Charles the Third."

Another problem to deal with was sumptuary laws that barred lower class people from wearing the fancy garb reserved for nobles. Since actors were lower class, they couldn't wear costumes representing nobles unless they had special licenses from the queen.

THE BEGINNINGS OF THE MODERN STATE (c.1450-1500)

Just as the turmoil of the Later Middle Ages had cleared the way for sweeping economic, cultural, and technological changes in Western Europe, it likewise produced significant political changes that led to the emergence of a new type of state in Western Europe: the nation state. It did this along five lines of development, four of them corresponding to various nation-states in Europe and the other having to do with the overall decline of the Church and nobles which helped lead to the revival of towns and middle class allied to the kings.

The later 1400's saw kings in Western Europe picking up the pieces left by the turmoil of the last century in order to build stronger states. However, this process of unification, or in some cases reunification, involved more violence and warfare. In England, the aftermath of the Hundred Years War saw a period of civil strife known as the Wars of the Roses (1455-85) over control of the throne. In the end, Henry Tudor, who became Henry VII, triumphed and restored order with such new government institutions as the Star Chamber.

The English Language and the Hundred Years War

The real importance of the Hundred Years War is largely revealed in the English language. Did you ever wonder why we call:

**the animal a cow, but the meat beef;
the animal a pig, but the meat pork;
the animal a sheep, but the meat mutton;
the animal a chicken, but the meat poultry?**

The answer lies in the class system of medieval England. The kings, nobles, and upper clergy, who were descended from the Norman French who had conquered England in 1066, still spoke French at the beginning of the Hundred Years War (1337). After all, many of them had lands on both sides of the Channel and saw little distinction between the two lands, except that they could understand and talk to French peasants. Since they had regular access to meat,

they used the French derived words: beef, pork, mutton, and poultry.

On the other hand, the Saxon peasants, who spoke English, were only familiar with the animals on the hoof, so they used the old English words: cow, pig, sheep, and chicken.

However, by the end of the Hundred Years War (1453), the English kings and nobles had been driven from France and were speaking English, although it was now a blending of the Norman French with the Old English (based on Germanic Saxon), so we still have Saxon derived words for the animals, but French derived words for their meat.

Not only had the English ruling class' language changed, so had their outlook, which was now distinctly English instead of continental. France and England have been separate nations ever since.

France, badly hurt by the Hundred Years War, gradually reunified as the Valois kings regained control of Picardy (1477), Anjou (1481), and Brittany (1491). The greatest challenge to the French kings came from the powerful and aggressive Charles the Bold of Burgundy. Charles controlled both Burgundy and the Low Countries (Flanders and the Netherlands) and threatened to become a major power in his own right until he met disaster at the hands of the Swiss pikemen in a series of battles ending at the Battle of Nancy (1477). With this potent threat removed and Burgundy also back under French control, a strong unified French state was emerging by 1500 after some 150 years of conflict.

A unified Spain also was born by 1500. The key event here was the marriage in 1469 of Isabella of Castile to Ferdinand of Aragon, which united most of Spain under their joint rule. (However, the two states continued to function largely as separate administrative entities for generations to come.) The final piece of the puzzle was put into place when the last of the Spanish Muslim states, Granada, was conquered in 1492. Among other things, this freed the new Spanish state to fund the voyage of a Genoese captain named Christopher

Columbus who was looking for new routes to the spices of the East.

Since Ferdinand of Aragon and Isabella of Castile (above) were too closely related to legally marry, they needed a special papal dispensation, which the Archbishop of Toledo duly forged for them.

“We who are as good as you swear to you who are no better than we, to accept you as our king and sovereign lord, provided you observe all our liberties and laws; but if not, not.”--Loyalty oath of Aragonese nobles, showing the weakness of the Aragonese monarchy at the time.

Spanish wool and Merino Sheep

The introduction of the Merino sheep into Castile from North Africa about 1300 transformed Castile’s economy and brought it into closer contact with the outside world, which wanted the wool. A special organization, the Mesta, supervised the seasonal migrations of these animals between their summer pastures in the North and winter pastures in the South.

Even Germany, fragmented after centuries of feudal strife and the emperors' struggle with the Papacy, saw its fortunes seem to revive with the rise of the Hapsburg Dynasty that controlled the imperial throne at this time. This family, through a number of astute marriage alliances, would come to control Austria, the Low Countries, Hungary, and Spain along with its Italian possessions and American colonies. In fact, as impressive as this empire looked, it worked to Germany's disadvantage since it would trigger a number of wars to crush the Hapsburg "superpower"-- wars that would use Germany as a battleground and ruin it. Therefore, by 1500, nation states were evolving, having their own strengths and problems.

Strengths of the new nation-states consisted of four main pillars of support: money, which in turn enabled kings to pay for professional bureaucracies and mercenary armies, and control of the Church. This mixture of medieval and modern elements

underscores the transition of Europe from the medieval to modern era.

Finances. The old medieval sources of revenue, such as feudal dues and income from royal lands and monopolies, were totally inadequate for the greater burdens, which the new types of government and army placed on Renaissance kings. Borrowing money against future tax revenues was a dead end that just got kings into deeper trouble, although that was commonly the practice. However, more regular taxes had to be collected. In France, the "extraordinary" taxes the townsmen had granted the crown to drive out the English in the Hundred Years War were collected annually and became a permanent tax, the *taille*. In Spain, the crown increased sales taxes to boost revenues. In England, the king was unable to get a high permanent tax granted to him by Parliament. He did increase his control over revenues for such things as customs on wool and cloth. Luckily, England was an island and in less need of a large expensive army and bureaucracy than states on the continent. Overall, Renaissance kings by 1500 were still faced with serious financial shortcomings. However, no one else in their realms possessed the resources to effectively challenge them. Along with their bureaucracies and armies, their finances presented a picture of the European state in transition from the medieval to the modern era.

Bureaucracies consisted mainly of members of the middle class with the education and experience needed to run the government. Since kings were usually desperate for money, they resorted to selling government offices, a practice known as *venality of office*. This system had its good and bad points. The main good points were that it provided the king with some much needed cash and officials who showed more efficiency and loyalty to their king than the old feudal nobility had.

The main drawback was that such a system bred corruption, since money, not ability, was often the key to gaining office. Bureaucrats tended to assume their own consciousness as a class, maintaining a common silence to thwart any attempts to weed out corruption. They could often successfully resist or slow down reforms or other policies they did not like. But, for all the problems the new bureaucracy created, it was still more efficient than the old

feudal system and gave kings a far greater degree of control over their states.

The new warfare. Renaissance armies told a similar story, being somewhat unruly but still better than their feudal predecessors. The ranks were now filled with mercenaries who fought until the king's money ran out. This gave the king much longer campaigning seasons than the forty days that feudal vassals typically owed. But it could still present some serious, and, at times, embarrassing problems. As soon as the king ran out of money, such armies would often desert or refuse to fight any longer. Also, since they were not usually natives of the state they were fighting for, they often had no qualms about plundering the people they were supposedly defending. Despite these drawbacks, Renaissance armies gave kings in Western Europe much tighter control over their states, largely because they were so expensive that no one but kings could afford to maintain them.

Part of that expense lay in the new type of warfare emerging by 1500. Although heavily armored knights were still prominent, their role was being reduced by two new ways of fighting, one medieval and one modern. One of these, reminiscent of the old Greek and Macedonian phalanxes, was massed formations of pikemen who now formed the core of the Renaissance army. Until the early 1500's, the Swiss were reputedly Europe's best pikemen, and every prince wanted Swiss mercenaries in his army, no matter what the cost. In the 1500's, German pikemen, known as *landsknechte*, and Spanish pikemen organized in formations known as tercios would rival the Swiss in their reputations for ferocity on the battlefield.

The other new and expensive element emerging in the new warfare was gunpowder. Hanging on the flanks of each pike square were men wielding primitive muskets. Such guns were heavy, hard to load, and even harder to aim accurately. They also presented the danger of blowing up in their users' faces. Still, they could be very deadly when fired in massed volleys, having a range of up to 100 meters. Gradual but constant improvements, such as the matchlock that freed both hands for aiming, made them increasingly effective throughout the 1400's and 1500's. As a result, the number of musketeers, and their cost, gradually climbed throughout this period. The combination of guns' firepower with

the solid pike formations proved to be the most potent military innovation of the Renaissance. It ruled Europe's battlefields until the later 1600's when better muskets and the bayonet phased out the pikeman for good.

Artillery was another important, but expensive, element in the Renaissance prince's army. Smaller and more mobile cannons were made for use in pitched battles as well as sieges. There was no standardization in the Renaissance artillery corps, each cannon being made by an independent contractor. The French, with Europe's best artillery, had 17 separate gauges of artillery requiring 17 different sizes of shot. The Hapsburg emperor, Charles V, had 50 different gauges. Obviously, this could create untold confusion in the heat of battle.

The advent of artillery made the tall thin walls of medieval castles obsolete, since they were so easily breached by cannons' firepower. However, this did not make fortifications obsolete. By the early 1500's, a new style of fortifications, the *trace Italienne*, was coming into use and slowing down, if not stopping artillery. These new fortifications were much thicker and more elaborate than their medieval predecessors, having multiple sets of walls, moats, and bastions set at different angles to one another to provide flanking fire from various directions against any enemy assaults. As with muskets and artillery, these new forts were so expensive that only kings could afford them or, more properly, afford to go into debt to bankers to buy them. And, by the same token, this increased the kings' power and put any rebellious nobles more at the kings' mercy.

This new type of warfare and army showed the beginnings of some aspects we associate with modern warfare. For one thing, the new technology and size of the armies made warfare much more expensive. It was also very destructive to any inhabitants unlucky enough to be in the path of these plundering mercenaries and their hordes of camp followers. The seventeenth century general, Albrecht von Wallenstein, once said he could better support an army of 50,000 than one of 20,000 since it could more effectively plunder the countryside. This says a lot about supplying such armies and its effect on military strategy: fight in the enemy's territory and make him pay for the war. Finally, the new warfare was much bloodier than the medieval

warfare that preceded it. We find nobles complaining because any low born peasant with a small amount of training and a gun could blow them out of the saddle. Even more significantly, the humanists condemned warfare for its bloodiness, no matter to what class. Throughout the modern era, that outcry has slowly gained force along with the growing destructiveness of warfare.

The Church was still the largest single landholder in Western Europe, making it mandatory for kings to control this vital source of revenue and propaganda. Luckily for the kings, the Church's power and prestige were seriously weakened by the popular discontent and corruption that climaxed with the Great Schism. In France, kings had gained the loyalty of the local clergy against the Italian higher clergy appointed by the popes and won their struggle to rule the French clergy in the Pragmatic Sanction of Bourges in 1438. This recognized the king's claim to the Gallican Liberties, transferring the direct loyalty of the French clergy from the pope to their king.

Elsewhere, the story was similar. In England, during the Avignon Papacy of the 1300's, kings had limited the right of foreign clergy to visit England and also restricted English clergy in their right to appeal to foreign (i.e., papal) courts. In Spain, the crown came to dominate the Church and, with it, the Inquisition. In all these countries, levying Church taxes was subject to the approval of the kings, who often made a deal to get a percentage of the taxes for themselves.

In addition to the structure of the emerging nation-state, peoples' attitudes toward that state were also in transition from a very personal feudal outlook to a broader concept of a nation. There was a growing awareness among various peoples that there were factors, such as language and culture, making them unique as nations. But the fully developed form of nationalism we are familiar with was still several centuries away. During this transitional period, the loyalties of people focused largely on the person of a king rather than on the nation's people as a whole.

Limits to the Renaissance state's power. We should keep in mind that, while the Renaissance state was a vast improvement over the feudal anarchy of the Middle Ages, it was still rudimentary and highly inefficient when compared to the

modern state. There were three main limitations to state building at this time.

First of all, the decentralized chaos of the Dark Ages had given rise to a multitude of local institutions and customs, rights, and inherited titles and offices. France alone had some 300 local legal systems (run by the local lords, bishops or abbots, towns, guilds, etc.) dating back to a time when there was essentially no central government. In the Netherlands there were 700. The force of tradition with centuries of history to back it up made it well nigh impossible for kings to do away with these offices, customs, and privileges. A good example of this were the *parlements*, local French courts which could modify the king's laws, delay enforcing them, or even refuse to enforce them if they thought those laws interfered with long established local customs and traditions. As a result, kings were forced either to work around the old offices by creating new parallel offices that would very gradually take over their functions, or incorporate the old offices into the new state apparatus. What this meant was that any regularization of government institutions and practices on a national scale was still centuries away.

A second problem was the continued existence and aspirations of the nobles. While we have seen them suffering from a prolonged decline since the High Middle Ages, they remained somewhat resilient as a class. One big reason for this was that they were still seen as *the* class to belong to, and many middle class merchants and bankers were eager to buy noble titles and lands so they could carry on like the nobles of old. A prime example of this was the Fuggers of Augsburg, Germany, the richest banking family in Europe, who bought noble titles and lands and passed into idle noble obscurity. Aiding this process were the kings who were always in need of cash and willing to sell noble titles and offices to anyone with the money. As a result, fresh blood kept infusing the nobility with new life. Unfortunately, these nobles, of whatever origin, could still be quite troublesome and lead revolts against their rulers, as happened in the Netherlands (1566), England (1569), and France (1582).

A third problem was the kings' inability or unwillingness to stay out of debt and pay their armies and bureaucrats. This encouraged corruption in the government and plundering and

desertion by the mercenaries, which further reduced the kings' revenues and ability to pay their bills, leading to more loans at high rates of interest, and so on. Finally, although kings could control their national churches, they could not control the medieval mentality still linking politics and religion and causing disastrous wars over religious issues. This especially became a problem after 1560 in the repeated religious wars between Protestants and Catholics.

The "New Diplomacy". Despite these problems, a new and more dynamic type of nation state was emerging by 1500. And once kings had affairs within their own borders reasonably under control, they started extending their involvement in diplomacy outside of their states. By 1500, we see Western Europe starting to function as an integrated political system, whereby one state's acts affected all the other states and triggered appropriate reactions. This new interdependence and sensitivity to other states' plans and actions sparked the beginnings of modern diplomacy. Two factors aided this process of outward expansion, and, once again, they were a mixture of medieval and modern forces.

Among the older methods still used to consolidate and improve a prince's position, the most notable was the marriage alliance. Rulers still thought of their states as their property. That property could be passed on to their sons, and it could be added to by marrying into another ruling family and assuming all or part of that family's property (i.e., state) as part of the deal. A number of such marriages took place in this period. Henry VII of England married Elizabeth of York, the heiress of his chief rival to the throne, a union that gave him undisputed claim to the crown. Charles VIII of France married Anne of Brittany and tied that region much more closely to the French king's interests.

Certainly the most spectacular example of dynastic empire building through marriage was the Hapsburg Empire, which controlled most of Western Europe in the first half of the 1500's. In 1469, Ferdinand of Aragon married Isabella of Castile, thus uniting Spain under one house, although the two governments functioned separately for some time. Meanwhile, the Hapsburg emperor, Maximilian, had wed Mary, duchess of Burgundy, and added Burgundy and the Low Countries (Flanders and

Holland) to his family lands in Austria and the Holy Roman Empire. Finally, their son, Philip, married Ferdinand and Isabella's daughter, Joanna, to seal an alliance in reaction against the French invasions of Italy starting in 1494. The product of that union, Charles V (Charles I of Spain), inherited most of Western Europe: Germany, Austria, the Low Countries, most of Italy, and Spain along with its American holdings. As a contemporary saying put it: "Others make war, but you, happy Austria, make marriages."

Marriage alliances alone were not enough to keep one diplomatically safe. For one thing, they created nearly as many problems as they solved. Since the network of marriage alliances was so extensive and interlocking there were almost always numerous claimants for vacant thrones whenever a ruler died childless. Such a situation often triggered wars, despite the original intention of the marriage alliance to stop such wars. Second, the Renaissance, with its increased political interdependence between states, created shifting alliances to maintain or improve their positions. This required a ruler to keep a much closer eye on what other states were doing so that they could not surprise him by switching alliances or suddenly declaring war. This led to permanent resident ambassadors, forerunners or our own modern diplomats.

Like so many other innovations, the idea of keeping permanent ambassadors at other rulers' courts originated in Italy. Previously, negotiations between states involved sending special ambassadors only for special occasions, such as a treaty of alliance or celebrating a dynastic marriage. By 1450, a delicate balance of power had evolved in Italy between its five main states: Milan, Venice, Florence, the Papal States, and Naples. The weakest of these states, Florence, felt nervous about its more powerful neighbors and wanted to maintain the balance of power to keep any one of them from threatening its own security. Therefore, it started maintaining permanent resident ambassadors at the other states' courts.

During the Renaissance, these officials were mainly of lower noble and middle class origin. They were expected to maintain themselves in the high style of their home court while being engaged in information gathering, which amounted to little

more than spying. They had to send weekly letters home, often in code, repeating all pertinent facts, rumors, conversations, and character descriptions they could come up with. All this was done at their own expense, which many of them could not afford. We have letters from such men, pleading with their home governments not to force them to serve. Usually such pleas were to no avail.

Physiognomy

Since at least the time of Aristotle, people believed one could figure out someone's character by looking at his or her face. They especially liked to compare them to the personalities of animals they may resemble.

For example, someone who happened to look like a pig was judged to be messy and unpleasant, while someone with the features associated with a lion was thought to be brave and noble.

Even as recently as the 1930s the Nazis used this pseudo-science, known as physiognomy or phrenology to back up their racist theories. Especially disturbing is how they compared Jews to rats, and even now we still typically use the Nazi term extermination of the Jews instead of murder to describe the Holocaust.

Spies

Besides ambassadors as quasi-spies, rulers liked to send real spies to foreign courts, partly to keep an eye on their ambassadors. Different countries favored different covers for their spies. The French liked to use nobles, because courts were always full of nobles anyway. The Florentines preferred bankers, since kings always needed loans from bankers who would want to know why they needed the money. The Venetians relied on doctors, who might have access to rulers and officials while they were delirious with fever and therefore prone to spilling secrets. And German states sent clergy who might be directly or indirectly privy to the confessions of rulers and officials.

There was no diplomatic immunity then, and the resident ambassadors suffered accordingly. Foreign courts saw them as spies and treated them as such, subjecting them to hostile treatment, insults, surveillance, imprisonment, and even torture. To add insult to injury, the home government often did not believe the letters these men sent home and kept spies at the court to watch their own diplomats. When important negotiations were to take place, the home government still appointed special ambassadors of high noble status to do the job.

In 1494, Charles VIII of France invaded Italy. This prompted the intervention and fateful marriage alliance of Spain and the Holy Roman emperor, Maximilian, mentioned above. It also touched off a series of wars that devastated Italy and ended its leadership in European affairs. All these wars and shifting alliances caused the great rulers of Europe to start maintaining permanent ambassadors at each other's courts. Over the years, as resident ambassadors became a permanent fixture of diplomacy in Europe and the world, their status and treatment would improve. Florence's policy of maintaining a stable balance of power would also spread northward and become a cornerstone of European and global diplomacy in the centuries to come.

Richard III and History

When the 10-year old Edward V (a Lancastrian) succeeded as king in 1483, Richard, Duke of Gloucester, was named his protector. In that capacity, he took Edward and his brother, Richard, prisoner and locked them in the Tower of London. He then had their mother's marriage (and therefore the boys themselves) declared illegitimate. They died soon afterward, possibly murdered by Richard, but no conclusive evidence exists. Richard had himself declared king, Richard III, and ruled two years before being defeated and overthrown by the Lancastrian Henry Tudor, who became Henry VII, thus ending the Wars of the Roses.

Richard III has gotten a lot of bad press from history, especially solidified in Shakespeare's portrayal of him as a deformed hunchback. Only recently have historians shown he was

probably not deformed or as bad as typically portrayed. So how did he get this reputation?

Much of it probably comes from the Tudor dynasty's hypersensitivity about the legitimacy of their rule on two accounts. First, Henry Tudor had taken the throne by force. Secondly, since Edward V had been declared illegitimate by Richard III, so had Edward's sister, Elizabeth of York, whom Henry married to secure his family ties and claim to the throne.

Thus to legitimize their rule through Elizabeth of York, the Tudors had to discredit and even demonize (as a hunchback) Richard III.

Therefore, anyone writing about Richard, such as Thomas More during Henry VIII's reign and Shakespeare when Elizabeth I was ruling, had best be careful in how they portrayed Richard, because anything they wrote that was favorable to him would meet with royal disapproval and maybe even charges of treason. By the time Elizabeth died in 1603 and a new dynasty, the Stuarts, took over, Richard had been dead for over a century and his portrayal in history was largely set.

The Swiss and Burgundian War

The Swiss were named after Schwyz, one of their original cantons (districts). (Their German enemies claimed the name came from the word for swineherd.) Technically, the Swiss were part of the Holy Roman Empire, but they didn't want to be. However, they had never presented a united front able to resist foreign interference until the mid 1400s when they started acting in unison to assert themselves by raiding Burgundian lands and cutting off the Alpine passes through which the Duke of Burgundy's Italian mercenaries reached his lands. The result was war between the Swiss and the Duke of Burgundy.

Previously, the Swiss had fought with halberds, heavy pointed axes mounted on long shafts. While this was effective in Swiss mountain passes, it didn't work so well on level ground against heavy cavalry. Thus the Swiss adopted a much longer two-handed weapon, the pike. One soldier with such an unwieldy weapon was fairly

helpless, but a large disciplined group of such men who held together in formation was a much tougher nut to crack. This was especially true for men on horses, which have a distinct aversion to impaling themselves on sharp sticks for the sake of the members of a bipedal species who happen to be sitting on their backs. In fact, it was for the sake of those horses that the front ranks of pikemen planted their weapons at an angle with their points at the height of the horses' chests.

If the battle got bogged down in a melee, the front ranks would open up to let old style halberdiers advance from the back ranks, since the halberd was a much more deadly and effective weapon at close range.

The first clash between the Swiss and Burgundians was at Grandson (1476). One way to break a pike square was to pour artillery shot into its densely packed ranks, which would have had murderous effects except for two things. First, the Swiss were on a hill making proper elevation of the Burgundian guns difficult. Secondly, Burgundian troops were blocking a clear field of fire. So, when Charles ordered his front ranks back, the rest of his army perceived this as a general retreat and fled the field. Luckily for the Burgundian troops, Charles had left a huge treasure in his camp (including his throne and jeweled hat), which the Swiss stopped to plunder instead of pursuing their defeated foes.

Later that year at Murten, the Swiss attacked Charles' mercenaries while they were occupied getting their pay. Once again, panic set in, except this time the Swiss pursued their fleeing enemies with great slaughter, killing 12,000 Burgundians while only losing 400 of their own men.

In January 1477 in the midst of a heavy snowstorm, Charles was defeated a third time at

Nancy, this time losing his life. As the poem that every Swiss schoolchild would have to learn goes:

*“Charles the Bold lost
at Grandson his treasure,
at Murten his courage,
at Nancy his life.”*

After Charles’ death, the lands previously belonging to the French crown were reincorporated into France. Charles’ daughter, Mary, inherited the rest, mainly consisting of the Low Countries (modern Belgium, Holland, and Luxembourg). When she married the Holy Roman emperor, Maximilian, her lands became part of the Hapsburg realm, mostly known as the Spanish Netherlands.

The fall of Granada & End of Moorish Spain

The prolonged war to conquer Granada (1481-92) began with the surprise attack and sack of the Christian stronghold Zahara on December 26, 1481 while the garrison was still sleeping off the effects of its Christmas celebration. The Spanish replied with an equally daring and successful assault on the Muslim fortress Alhama deep within Granada’s territory. What had previously been little more than border clashes between Muslims and Christians now became a fight for Granada’s very survival.

After two disastrous defeats, the Spanish did manage to capture the emir of Granada’s son, Boabdil. Realizing he could be more helpful to them as a free man, they released him to challenge his father for power, but only after he agreed to become a vassal of Spain if Ferdinand and Isabella helped him regain his kingdom.

At this point, the war became one of sieges and artillery. Ferdinand had established gun foundries, and between 1479 and 1485 the number of master gunners (mostly foreigners) he attracted into his service grew from 4 to 91. Serious discussions were also taking place considering the proper siting of guns, their ranges, and the number of shots needed to create a breach. At the siege of the supposedly impregnable fortress of Rondo, the Spanish developed the standard tactics for conducting

sieges over the next century, combining heavy artillery bombardment of the walls with continuous fire from arquebuses (early handguns) to keep anyone from coming out to repair their breaches. As was typical for sieges in this period, it was a combination of medieval and modern weapons and tactics that worked. In this case a trebuchet launched an incendiary over the wall and started a major fire. When the Spanish were able to cut the fortress’ water supply, the defenders were soon forced to surrender.

Instead of iron cannonballs, shaped stone balls, some recycled from trebuchet ammunition used in a siege a century and a half earlier, apparently were used exclusively in the Granada war... with the occasional exception of a human body. When a would-be assassin of Ferdinand missed his target through mistaken identity during the siege of Malaga, the Spanish cut his body into pieces and used a trebuchet to fire it back into the city. The defenders sewed the body back together and gave it a hero’s funeral. This was the last recorded use of a trebuchet in warfare.

In 1491 the Spanish closed in on the final Muslim stronghold, the city of Granada with its fabulous Alhambra Palace. On January 2, 1492 the Muslim ruler, Boabdil surrendered Granada to Ferdinand and Isabella who accepted the surrender wearing Muslim garb out of respect for their defeated opponents and new subjects (above). The reconquista was finally complete, and with it the unification of Spain.

Four months later, the Spanish monarchs gave their final agreement to send Christopher Columbus on his voyage to find a way to reach Asia by sailing west.

The Granada war trained the Spanish infantry in different types of combat and toughened them through exposure to extremes of heat and cold

and mountainous terrain. This experience would serve them well in the years to come both in the conquest of the Americas and the Italian Wars.

The New Warfare

The Hundred Years War had been in a sense the first modern war, since it used paid mercenaries instead of feudal nobles to do most of the fighting. The usual system was for mercenary captains to hire out a company of men to the king for a fixed price. The king would (supposedly) pay the captains who would (supposedly) pay their men. However, even when paid in full by the king, captains would often keep more than their fair share either by short-changing their soldiers or providing fewer soldiers than they were supposed to. If the king or a general decided to have a review, captains might borrow men from other regiments, force local civilians into line, or even have soldiers duck down and run to the end of the line to be counted a second or third time after being counted the first time.

The new recruits. Making matters worse, most mercenaries were drawn from the unproductive classes, nobles at the top and the dregs of society at the bottom, since pre-industrial economies could not afford to lose productive peasants and townsmen. One study of the English army in the Hundred Years War found that 12% of its recruits were condemned criminals who were given the choice to be executed or fight for the king.

Besides your normal day-to-day brutes, such armies especially attracted the more violent and psychotic members of society. Taking advantage of the loose discipline imposed on them, they would rape, murder, and pillage helpless civilians, regardless of what side they were on. Even if their comrades disapproved of such extreme acts of brutality, they were usually too scared to intervene on the civilians' behalf.

More likely these orgies of violence would spread through the army like a plague, creating an atmosphere that would draw in men who, under normal circumstances, would never think of committing such acts.

Not all the men (and the few women disguised as men) lured into these armies were psychos, just enough of them to influence or intimidate the rest who weren't. Many recruits were relatively innocent young men looking for riches, adventure, and a way to leave their farms and villages so they could see the world. Luring them in were unscrupulous recruiting officers who typically got them drunk, while promising glory, riches, and adventure (below). More often than not, what they got, if they survived at all, were disabilities and poverty.

Given the likelihood of eventually getting wounded over a prolonged period of service and the primitive state of medical care and surgery, soldiers were very likely to lose an arm or leg to amputation. Given the fact that such disabled veterans were not too popular with the civilian population they or their comrades had previously plundered, raped and murdered, they typically were reduced to begging. As the saying went: "Young soldier, old beggar."

Fashion history: slashed sleeves. According to one theory, the fashion for slashed sleeves during the Renaissance developed from the practice of stripping the bodies of the dead after a battle. If a soldier took a jacket that was too small for him, he would slash the sleeves vertically so it would fit. The practice caught on and became a major fashion statement in the 1500s.

New and old weapons and tactics. The Renaissance was an especially transitional period in terms of how wars were fought, seeing a continual shifting in how old and new weapons

were mixed and used. The one factor changing warfare on every level was gunpowder.

Cavalry. For example, the period saw the transformation of the medieval knight into a very different sort of fighter. Well into the 1500s, the heavily armored mounted knight remained a fixture on the battlefield, even as his effectiveness was being increasingly challenged, first by phalanxes of pike men, then by infantry armed with muskets and artillery, and finally by other cavalry armed with pistols.

Up until around 1540, firearms were impractical to use from horseback, because they required both hands to load and fire. One of the more cumbersome aspects of firearms was the matchlock mechanism for firing. This involved keeping a long slow-burning fuse lit and constantly repositioned on the serpentine (AKA hammer) of the gun so it could ignite the charge of powder.

Changing all this was the invention of the wheel-lock, a spring-loaded mechanism that ignited the powder with a spark triggered by bringing down a piece of iron pyrite or flint onto a piece of steel. When this was adapted to a much shorter firearm, the result was the pistol, a weapon a cavalryman could fire with just one hand while controlling his horse with the other.

The pistol's shorter barrel also gave it a much shorter range, thus forcing cavalry to still approach the enemy closely before firing. However, it proved more effective than heavy armor and lances, thus ending the days of the medieval knight by 1600.

The pistol did have its limits, however. For one thing, it still required two hands for loading and reloading, so in the heat of battle it was a one-shot weapon. Therefore, to increase their firepower, cavalrymen typically had two loaded pistols in saddle holsters and often one or two more stuck in their boots when going into battle.

Manufacturing the wheel-lock mechanism required the precision of a clockmaker. For example, the distance between the moving wheel and the static block had to be between .04 and .08 mm. to keep the finer grains of primer

powder, which were about 0.1 mm. from infiltrating the gear housing and jamming the gun. This and the gradual wearing down of the spring's power made it prone to breaking and also too expensive for infantry firearms. Not until the simpler and cheaper flintlock was invented in the 1600s would infantry be freed from constantly having to reset matchlock fuses.

Once a horseman had discharged his pistols, he needed a weapon for close-up combat. Thus the saber replaced the cumbersome lance and broadsword. As a result, cavalry armor also got lighter, with a full suit of armor being replaced by a breastplate, segmented armor covering the thighs, and heavy boots below his knees. The greater fluidity and maneuverability of cavalry battles required greater visibility, leading to more open helmets so cavalrymen could be more aware of their surroundings.

The function of cavalry also changed with their armor and weapons. Instead of the blunt force trauma of the frontal charge up the middle, cavalry operated from the flanks against other cavalry. Since they were faster than infantry, they generally joined and resolved their part of a battle first. Once one side's cavalry had won and chased the enemy cavalry off the field, they were supposed to attack the enemy's infantry in their now exposed flanks or rear to finish the battle.

However, cavalry were still nobles who fought more for their own glory than the sake of their lowborn infantry. Besides, the enemy infantry had muskets, which could hurt the cavalry and their horses, which was not a glorious way to die. It was a lot more glorious, lucrative and safer to chase other nobles and plunder their camp. Thus, regardless of how their cavalry did in a battle, the infantry were left on their own to decide the battle.

Infantry and the drill and march. One of the things lost with the fall of the Roman Empire had been its infantry's efficient way of fighting. The key to this had been the intensive training with the drill and march, which transformed a collection of foot soldiers into a well oiled fighting machine. Throughout the middle ages, battles were dominated either by cavalry, static

shield walls, or archers, none of which used the drill and march. However, the Swiss revival of the phalanx of massed pikes, especially as an offensive weapon, required a level of coordinated movement not seen since the fall of Rome.

The answer probably came from the Renaissance revival of a late Roman author, Vegetius, who wrote about why the Roman army had been so effective before it was infiltrated by barbarian warriors who refused to submit to the intensive training that came with the drill and march. Since there are surviving copies of Vegetius translated into various languages before 1300, it seems likely the Swiss were aware of him and adopted some of the Roman training techniques to their own needs. This seems especially likely when considering that there are accounts of the Swiss advancing rapidly in formation across battlefields, something that required a high degree of coordinated training, wherever the idea came from.

As firearms and artillery became increasingly important in European battles in the early 1500s, the pike formation as an offensive weapon became progressively less effective, as witnessed by their disastrous charge in the face of enemy artillery and muskets at Bicocca in 1522.

Instead, it became a largely defensive formation for protecting (and being protected by) formations of infantry with firearms. In order to gain a greater reach over their opponents, armies' pikes were gradually extended to as much as 18' in length.

Since it was cheaper to mass-produce than the wheel lock, the matchlock remained the firing mechanism on the arquebus and heavier musket until well into the 1600s. It was a cumbersome device, since the match had to be repositioned and blown on (to keep it burning) every time it was fired. Loading and firing it took about a minute for each shot. During reloading, a musketeer was much more vulnerable to attacks by enemy cavalry and pike-men.

Therefore, given the complementary vulnerability of pike men and musketeers to one another, it was natural for them to combine for mutual support and protection. However, it wasn't an easy task figuring out how to mix the two types of soldiers. At first, arquebusiers were placed in clumps on the flanks of the pike squares with little coordination in firing.

Soon they were organized to fire together in volleys for maximum effect and noise. Sometimes, as with the Spanish *tercio*, they were placed in blocs, known as horns of shot, on each corner of a pike square, but such formations rendered the rear ranks' fire ineffective, if not dangerous to their comrades in front. Another arrangement was to place them in front of the pike-men, providing a broader more effective field of fire against approaching infantry. As the enemy got nearer, they would retreat through the ranks of their own pike-men.

The real breakthrough came in the late 1500s when the Dutch leader, Maurice of Nassau, using military treatises by the Roman authors, Vegetius and Aelian, adapted the Roman countermarch to reloading and firing muskets.

Maurice adapted this rotating technique for musketeers who, after firing, would countermarch to the rear, allowing their comrades in the rear to step up, fire, and countermarch to the rear in turn, and so on. By the time the last rank had fired, the first rank had reloaded and was ready to step up and repeat the process. Contemporaries estimated this maneuver effectively tripled an army's rate of fire, as well making each rank's firing more effective, since everyone was firing from the front rank.

Part of a manual of arms that broke down loading a musket into a series of simple steps

Overall, firearms were an improvement over the crossbow and longbow. They could pierce armor at relatively close range. Compared to the bow, it was also easier to train soldiers to use firearms effectively. Compact musket balls were easier

and faster to manufacture and also affected less by crosswinds than were arrows or crossbow bolts.

On the down side, matchlocks were harder, if not impossible, to fire when it was raining, although bowstrings were also affected by such conditions. The musket and arquebus required more precisely calibrated and standardized ammunition than did the bow. Another problem was misfires or duds. An experiment in 1966 using 16th century muskets and modern powder resulted in 43% of the guns misfiring.

Matchlock firearms were also less accurate. This was because the musket ball's caliber had to be slightly less than the gun's barreling so that the smoke and residue from the explosion could escape. While this reduced the need to clean the gun, it allowed part of the explosive force to dissipate around the musket ball as well as causing it to veer off slightly in one direction or another rather than firing straight. As this error magnified with distance, it was particularly hard to hit a specific target at any distance.

Therefore, armies fired together in volleys, increasing the odds that someone would hit something. Psychologically, in addition to the louder noise, the volley seemed more effective since it brought down several targets all at once.

However, the musket ball's relatively low velocity and inaccuracy has led to one calculation that, as late as the Napoleonic Wars in the early 1800s, a man's weight in bullets still had to be fired for every man that was killed on the battlefield. Adding to their inaccuracy was the high expense of gunpowder, which eliminated or minimized a soldier's target practice. Even in the best-case scenario, the British army in the 1700s, recruits only got three practice shots per year. As a result, the command in battle wasn't "Ready, Aim, Fire." Rather it was "Ready, Level, Fire."

A matchlock gun was also dangerous for its user. For one thing, that live match he kept lit could detonate all the gunpowder on his person, and even spread a chain reaction to his comrades. In addition, such weapons could also overheat, with the threat of exploding during the process of loading. Then again, the main charge might not

ignite even if the priming powder fired, leading to the expression "flash in a (priming) pan". However, the musketeer might not notice this in the heat of battle and load a second charge that turned his gun into a bomb the next time he fired it. Another problem was backflash burns on the face when the priming pan ignited. To counter this, musketeers often wore floppy hats that they would pull over their faces before firing. Finally, repeated exposure to the firing of guns could permanently damage one's hearing.

Another issue often plaguing musketeers was the inconsistency of the gunpowder. At first, the powder was so finely grained that, when packed into a barrel, there was no room for oxygen between the granules. Thus a charge exploded from the outside in rather than simultaneously, wasting one-third of its explosive force. This led to corned powder (below), which was made by dampening the powder so its granules would stick together in irregular clumps that left room for oxygen in between them, thus allowing the charge to explode simultaneously with full force. Even then, the saltpeter had a tendency to settle unevenly in a barrel, creating an inconsistent mix of powder with equally inconsistent explosive forces for individual charges, depending on where in the barrel they came from. One solution was to shake the barrel before using the powder, but the friction that generated might cause the barrel to explode.

Artillery. The English at the Battle of Crecy Europe in 1347 during the Hundred Years War may have been the first to use artillery. Its main effect, if any, was to scare the French horses. But rulers soon realized the potential of cannons and started pouring huge resources into their development and production.

At first, a cannon's power depended on its size. Witness Mohammed II's monstrous cannons at the siege of Constantinople in 1453 and "Mons Meg" (below), the huge bombard made for Philip the Good of Burgundy in 1449, which weighed 5000 kilograms and fired a 250-

kilogram carved stone ball from a barrel nearly 50 centimeters in diameter. The huge size of these guns restricted their use mainly to sieges, since they were too difficult to maneuver in open field battles.

However, as metallurgy improved, smaller and lighter guns could be made that could both damage fortifications and be used in pitched battles. Even after the Burgundians invented a carriage that would be the standard design for hauling guns for centuries, transport was still a huge task. For example, it required seven pairs of horses or oxen each to transport a demi-culverin (an especially long siege gun with a thicker breech that could take the stress of larger charges of gunpowder, thus giving it a longer firing range). Just one covered wagon to haul ammunition required another nine horses.

Above: an early cannon foundry

At first, guns were cast around a plug known as a mandrel. However, if the mandrel moved, it created uneven sides, which could make the cannon fire crookedly and even crack or explode. In the 1500s they started casting solid barrels and boring out the center, which created a more precise fit for ammunition. Bronze, although ten times more expensive, was preferred over iron for artillery barrels, since it was less prone to create air bubbles in the casting, which led to guns cracking or even exploding when fired.

The ease with which cavalry could be mowed down by artillery fire made cannons and the men who operated them especially hated by nobles who would often cut off the hands of captured gunners. No wonder when one considers that at the battle of Ravenna in 1512, one cannonball supposedly killed 33 knights.

Demonstrations of artillery power were popular spectacles for the public, much like fireworks demonstrations today. Some gunners would mix

their gunpowder so it would make even more noise for such events.

Command and control. Without modern communications, it was particularly difficult for generals to keep in touch with their various units and coordinate their movements. Compounding this problem were two other things: The intense noise of battle and the clouds of smoke produced by thousands of guns repeatedly firing, thus creating “the fog of war.”

To transmit orders that could be heard over the din of battle, armies used fifes, trumpets, and drums that produced sound frequencies that were either high or low enough to be distinguished from the screams and explosions otherwise filling the air.

To cut through the fog of war, every regiment would have several brightly colored flags, all sharing one color or symbol, but each with a different marking so one could find specific officers and bodies of men. Such flags also served as the focal point of loyalty for soldiers within a unit as well as telling them where to move.

Regimental flags for a regiment of the Parliamentary army in the English Civil War

Identifying the enemy was another problem before regular uniforms started becoming the norm in the late 1600s, at first for individual regiments and later for national armies. Until then, regiments typically wore something of a particular color (often a leader's family colors) to be identified in battle: hat bands, sashes, and even certain types of flowers or sprigs of leaves.

Battle. Unfortunately, all these resources and innovations were designed for the destruction of other human beings in the chaos of battle. There is no way to convey in writing the sheer horror and psychological impact of combat, whether in

the Thirty Years War in the seventeenth century or Afghanistan in the twenty-first. However, one contemporary writer managed to convey some of the terror:

“The cruel shots, the crashing of armor plates, the splintering of pikestaves, the screams of the attackers as well as the wounded, the blare of trumpets, the roll of drums, the shrill sound of fifes.” And When over,..”the earth that is accustomed to covering the dead was herself now covered with corpses.”

Medical care. Not to minimize the sufferings and deaths that came from combat, but until the late 1800s far more soldiers died from disease, food poisoning (because of corrupt food contractors and the lack of refrigeration), malnutrition, starvation, and non-combat infections than ever died in battle. Even in the American Civil War (1861-65) two-thirds of soldiers’ deaths came from sickness. Add to soldiers’ deaths the much higher numbers of civilians that often died in the wake of armies bringing murder, famine, and epidemic.

Probably the biggest killer of soldiers was “the camp disease”, dysentery, a gastro-intestinal sickness caused by polluted water, the source often being an army’s own latrines when its officers or men didn’t have enough sense to put them downstream from their water supply. Other sorts of garbage and waste also piled up in a camp, attracting rats and various insects, while massive amounts of horse droppings, drew flies that spread typhus. Then there were the crowded conditions in which armies lived that helped spread whatever infections were floating around.

Maybe 10-20% of the soldiers in an army on the move would die each year, with camp followers dying at an even higher rate, especially babies, young children, and pregnant women. The rates

could be considerably worse when an army was settled in for the winter, for a prolonged siege, and particularly a long siege lasting through the winter. Add to this desertions, either to the other side or just to forage and pillage indefinitely, and one sees the constant recruitment efforts armies had to maintain. Although desertions supposedly brought the death penalty, officers often tolerated such actions during the winter when the army was usually inactive, because it created fewer mouths for the army to feed.

Then there was the issue of care for the wounded. With no understanding of germ theory, battlefield surgeons had only one way to keep wounds from getting infected with gangrene and killing their patients: amputation. Keep in mind there were no anesthetics, unless you count alcohol or a blow on the head to knock you out so you don’t feel the real pain. Thus surgeons needed several strong men to hold down the patient while quickly sawing off his limb(s). Given the high number of casualties after a battle and the need to keep from prolonging a patient’s agony, a surgeon’s reputation rested more on speed than accuracy.

Cauterizing the wound was usually done with a red-hot piece of iron, but sometimes by sprinkling gunpowder on the wound and lighting it. If the patient was lucky, he might survive the shock from the explosion.

Logistics. Unfortunately, the logistics of feeding and supplying these bigger new armies were often beyond the ability of the state to meet, especially as wars dragged on and ate up the resources needed to sustain a war effort. When kings ran out of money and couldn’t pay or supply their armies, soldiers reacted in two ways that were by no means mutually exclusive: mutiny and forage. For example, when Spain’s Army of Flanders went unpaid for 22 months, its men decided to sack Antwerp, the city they were

defending, in order to get their back pay. To their credit, the soldiers did first kneel and pray to the Virgin Mary to bless this action, known as the Spanish Fury, before engaging in rape and plunder.

Even worse, soldiers had to forage and plunder the countryside in order to survive. Besides undermining the discipline and organization of an army whose men may or may not come back, this was an even greater disaster for the civilians whose lands were stripped bare of everything they needed to survive. What soldiers couldn't consume or take with them, they often burned.

Pleas by the peasants for mercy were rarely heeded. Many peasants, having lost their homes, fled to the woods to subsist on whatever they could find there. When given the chance, peasants would take vengeance on stragglers, no matter which side they supposedly represented. Some peasants even organized into armies to defend their homes against both sides in the war.

Since plundering was technically against regulations, officers would occasionally crack down when it got especially out of hand. A few unlucky soldiers would be caught and hanged, serving as a very temporary warning to the others.

Compounding this problem and swelling the armies' numbers were camp followers: contractors supplying the army, merchants, professional gamblers, women (there either willingly or not), and children (especially after nine months of war). Half an army's numbers might be made up of such people, with several babies even being born each week. (One doesn't generally think of armies needing their own maternity wards.)

Another factor in the equation was the larger number of calories (and greater amount of food) people then had to consume back then, since most every task involved physical labor, either

by humans or beasts of burden. One estimate done by the U.S. Army calculated the average farmer in the 1800s needed to consume 5,000 calories a day to maintain himself.

It probably wasn't too different for soldiers in the 1500s marching with their weapons and all their worldly possessions on their backs. Add to all this the food needed for cavalry horses and beasts of burden and then all the water such an army would need on a daily basis. The figures can be staggering. This also helps explain why 85-90% of the population was needed just for agriculture.

The Renaissance State and the Church

In order to understand the importance of the Church to state building in Western Europe during the middle ages, keep in mind that at any given time and place, the Church owned 20-30% of the land and that land was the main source of power and wealth then. Thus controlling elections of bishops and abbots (who ran most of the Church's lands) was crucial to rulers. For example, it's estimated that 74% of the army Otto I of Germany took into Italy in 961 was drawn from Church lands.

Not only did bishops and abbots supply troops, they also fought. Consider Odo, bishop of Bayeux (where the Bayeux Tapestry was woven) and half-brother of William the Conqueror, who was in the front ranks of the Norman army bashing in Saxon skulls with his war club at the Battle of Hastings. (He used a war club, thinking it might avoid shedding blood and therefore making killing an enemy more acceptable to God.)

In *The Song of Roland* there is Archbishop Turpin who leads a charge and kills his enemy, inspiring the comment about how well the Archbishop defended his people with his crook, a double entendre referring to the shepherd's crook, a symbol of a bishop watching over his flock of believers spiritually, but also using it to drive off and kill any predators.

Of course, by 1500, the Church was mostly out of the business of waging war, but its wealth (as seen in the rich vestments of the clergyman

pictured in Fra Angelico's painting below) could be a valuable source of revenue for kings, especially since it generally had to get the kings' permission for special fund-raising drives in return for giving them a cut of the take.

Then there was also the "power of the pulpit". Without mass media, the Church was the most effective organization for spreading orders and propaganda to the people on Sunday mornings. The king would send his message to his archbishops, who passed it on to their bishops, who communicated it to their parish priests, who delivered it to the people on Sunday morning. Therefore, if the king could control the clergy, he could control public opinion and keep the people's loyalty. The power of the pulpit may have been the most valuable attribute the Church had to offer kings. This also helps explain why so many kings were so opposed to the Protestant Reformation, since it threatened to dismantle the primary line of communications between the king and his people.

Financing the Early Modern State

One strategy for borrowing money was called tax farming. If a king needed or wanted more money than he could get in taxes at the time (which was usually the case), he could sell the right to collect part of next year's taxes to a financier in return for cash then and there. Of course, this would reduce his tax revenues for the next year, while his need and or desire for money stayed at least the same. So for that year he could sell two tax farms for the following year (one to make up for the taxes lost to a tax farmer for that year and the second to get the extra revenue beyond his normal taxes).

So what did the king do once he had no more tax farms left to sell for the next year? No problem. He would sell tax farms two years in advance, and then three years in advance, and so on. By the end of the Thirty Years War in 1648, the French monarchy was tax farmed a full five years in advance. In other words, it couldn't collect taxes for itself for another five years. It almost makes modern state spending look good.

Kings would also take out conventional loans, usually at high rates of interest, because they were such bad credit risks. If they defaulted, which even the Spanish monarchy did three times in the 1500s at the height of its power, bankers were out of luck. Of course, a year or two later, the kings needed money again and would cut a deal with the bankers that they would pay back the principle, but not interest, on the previous loan if the bankers would float them a new loan.

One might wonder what happened to the financiers who bankrolled the early modern monarchies, such as the Usurers pictured below by *Marinus van Reymerswaele*. According to a study of such men in 18th century France, two-thirds of them ended up in jail, usually on trumped up charges of treason. Hmm.

History's first major bank crash. In the 1340s, Edward III of England took out massive loans from the main banking houses of the day in Florence, the Bardi and Peruzzi, to finance the first stage of the Hundred Years War. When he defaulted, not only did the Bardi and Peruzzi banks crash, so did many of the banks and businesses they were associated with, triggering a chain reaction across Europe that set its economy back for several years much like the Stock Market Crash of 1929 did 600 years later.

Travel and Communications

Sending letters before there were public post offices was largely a hit-or-miss proposition. There were two ways one could send letters, private postal companies or friends, acquaintances, merchants or anyone else who happened to be going in that direction. Private companies were probably more reliable, but also expensive. With friends, etc. going in the right direction, there was no guarantee of how quickly or leisurely they might travel. They might not survive the journey to get the letter there. Or they might lose the letter or forget to deliver it. Then again, it might get soaked in a rainstorm or stolen by brigands.

A key element in *Romeo and Juliet* is a slow-moving messenger carrying the news that Juliet

is actually alive, but he is passed by Romeo's friend to tell him that Juliet was dead. Like any writer, Shakespeare wanted to make as many details in his plays as believable as possible, such as a sixteenth century Newman carrying the mail. He had enough to sell his audience in the way of Juliet's harebrained teenage scheme of a fake suicide.

Travel times, of course, were much slower back then. It is estimated that travel from Rome to Venice would take two to three days and from Rome to Paris about twelve days. Travel by sea from Venice to England would take 20 to 30 days, the huge variation being due to weather.

The Italian Wars (1494-1559)

The Peace of Lodi brokered by Lorenzo the Magnificent of Florence in 1454 had held up for 50 years. However, in 1494, all hell broke loose upon Italy in a series of wars referred to the Great Italian Wars.

It started when Pope Innocent VIII excommunicated Ferdinand I of Naples over his refusal to pay feudal dues to the papacy. The pope then encouraged Charles VIII of France, who had a remote claim to the throne of Naples going back to the 1250s, to come claim his inheritance. The pope settled his quarrel with Ferdinand and lifted his ban of excommunication, but the bait had already been cast.

Things got more complicated in 1494 when Ludovico Sforza took power in Milan, which the new king of Naples, Alfonso II, also claimed. This spurred Ludovico to invite the French in to claim Naples, never thinking they might want to take Milan as well.

In addition, Charles VIII of France had the surviving claim to, of all things, the crown of

Jerusalem and wanted to use Naples as a base for a crusade to Palestine. Not being too bright or farsighted, he secured his borders by giving money to Henry VIII of England and lands to Ferdinand of Spain and the Holy Roman emperor, Maximilian.

In 1494, he crossed the Alps with an army of 25,000 men, including 8,000 Swiss mercenary pike-men, the most feared mercenaries of their day. After shocking the Italians by brutally massacring the garrisons of two small towns, Rapallo (left) and Fivizzano (right), Charles occupied Florence (below) and moved quickly to take Naples.

The Italians were used to a relatively bloodless style of warfare where condottiere (mercenary captains), not wanting to risk collecting their paychecks, typically maneuvered harmlessly around each other before signing a truce.

Therefore, they were shocked by the speed and brutality of the French invasion. Equally shocking was the effectiveness of the French artillery on their fortifications.

However, the French occupying Naples were in for a shock of their own in the form of a new disease, syphilis, possibly brought by Columbus' men from the New World. Having no previous contact with this disease, it hit with especially terrible virulence, forcing Charles to lead his army back up Italy and for home. (Because of this incident, Syphilis was referred to as the "French Disease" for centuries.)

Meanwhile, in reaction to Charles' invasion, Venice had formed the Holy League with Milan, the Pope, Spain, England, and Maximilian I, the Holy Roman Emperor. Under Venice's leadership they sent an army to block the French. On July 6, 1495, they clashed near the village of Fornovo. Despite the French being heavily outnumbered, it was a bloody, but indecisive battle, costing the French all their plunder from Florence and Naples and forcing them to retreat.

While technically a victory for the Holy League, Charles was allowed to return home peacefully. Two years later, he banged his head on a door and died. But that was far from the end of the matter.

In 1496, largely reacting to French aggression, the Hapsburg prince, Philip “the Handsome”, married Joanna “the Mad” of Spain.

Their son the emperor Charles V (Charles I of Spain) would inherit Spain, the Holy Roman Empire, the Two Sicilies, the Low Countries, and the growing American Empire. France, caught in the middle of this far-flung realm, would fight to break out of this ring of Hapsburg lands in a series of wars that would rage on and off for the next 250 years. The Italian Wars were turning into the European-wide Hapsburg-Valois wars.

In the Second Italian War (1499-1504), Louis XII of France (above left) seized Milan and signed a treaty with the emperor Maximilian recognizing French conquests in Northern Italy. Louis then allied with Ferdinand of Spain (above right) to take Naples, with himself getting the crown and Ferdinand getting some of its lands. However, after seizing Naples, the allies had a falling out over its crown. After two Spanish victories, the two powers recognized French control of Milan and Spanish control of Naples in the Treaty of Lyons.

Meanwhile, Pope Julius II, worried about Venetian, rather than French, aggression, formed the League of Cambrai with Spain, France, and the Holy Roman Empire. After defeating Venice, the pope switched sides and joined Venice against France, declaring a Holy League that included Spain, the Holy Roman Empire, and England.

In 1512, the French, through a combination of firepower and cavalry, practically annihilated a Spanish army at Ravenna. However, the French general, Gaston de Foix, was killed and the Swiss seized Milan, forcing the French to retreat home. The victorious allies then had a falling out over the spoils, causing Venice to switch sides and ally with France.

The French king Francis I invaded Italy again, but was defeated in 1512 by the Swiss pike-men and League forces at the Battle of Novara while Spanish forces the next year defeated and scattered a Venetian force, France’s ally, at La Motta. Meanwhile, the war was spreading across Europe, as Hapsburg forces clashed with Swiss pike-men in French pay in Northern France. In 1513, English King Henry VIII defeated the French at the Battle of Guingate, also known as the Battle of the Spurs because of the myth that the French cavalry fled so quickly that all the English ever saw were the spurs of their fleeing enemy. As a diversion against France’s enemy, England, the Scottish king, James IV, invaded England in 1513, only to be defeated and killed at the Battle of Flodden Field.

The scene switched again to Italy where the French defeated the Swiss at the Battle of Marignano (September 14-15, 1515). Previous to the battle, Francis had hauled 40 (or 70) heavy artillery in a remarkable passage across the Alps on a newly built road. Marignano was an especially brutal and confused battle that lasted two days, even continuing under the light of the moon until troops on both sides just collapsed where they were and went to sleep. Even the French king was reduced to drinking water from a ditch filled with bodies.

The next day, the French alternated cavalry charges, which served to keep the Swiss in tight hedgehog formation, with artillery bombardments that tore into the densely packed Swiss ranks, wreaking horrible carnage and winning the day. They said Marignano was fought “not between men but between ferocious giants”. When it ended, 12,000 Swiss pike-men lay dead on the field, and with them died much of Swiss military power.

In the subsequent treaties of Noyon and Brussels, the League ceded all of Northern Italy to France and Venice. But the wars were far from over.

After Marignano, Switzerland’s limited manpower was largely depleted by continuous

wars. Replacing them as the most sought after mercenaries would be German Landsknechts.

The two rivals met in 1522 at Bicocca, which signaled the end of the pike square as a stand-alone formation. Without waiting for their artillery to clear the way, the Swiss charged into a hail of artillery fire and then got stalled trying to scale a rampart while enemy arquebuses (light muskets) mowed them down. In their wake, they left 3,000 dead. If Marignano wrecked Swiss manpower, Bicocca broke the myth of their invincibility. After this, they would play only a minor role in future conflicts.

By now, the Spanish had developed the *tercio*, a formation better coordinating the use of pikes and firepower. It consisted of a solid square of pike-men with a rectangular “horn” of arquebusiers at each corner. Thus the pike square was being transformed from an offensive weapon, as the Swiss originally used it, to a defensive formation to protect its firepower. Spanish tercios would be the terror of Europe’s battlefields for the next century, causing enemy soldiers to desert just on word of their approach.

However, the *tercio* had its limits. Its pike square was too deep to make effective use of the back ranks, while the horns of muskets on the corners wasted much of their firepower. This was largely rectified at the battle of Ceresole in 1542 where both armies put a line of arquebuses behind the front line of pikes. While the pike-men were engaged in a melee, the arquebusiers opened fire with horrific effect.

At Pavia in 1525, Francis I rashly led the French cavalry in a charge that got him captured by Charles V’s army. He was released upon promise of good behavior, but he was soon back on the attack against Charles.

On May 6, 1527, Charles V’s unpaid Spanish Catholic and German Lutheran troops broke into Rome and ran amok, torturing, murdering, raping and pillaging for weeks on end while Pope Clement VII could only look on helplessly from the safety of the Castel Sant’ Angelo.

Cardinals were humiliated and tortured, especially by Lutherans.

Sacred vessels and works of art were destroyed or melted down.

Children were thrown out windows to extract the location of hidden wealth.

Women, including nuns, were raped.

After the sack of Rome, Florence, France’s ally, threw out the Medici and declared a republic. This brought down the wrath of Charles V who besieged Florence. With Michelangelo in charge of its recently improved fortifications, the Florentines bitterly resisted the imperial siege for 10 months (1529-30). After a stubborn defense, they finally surrendered and the Medici returned, establishing themselves as the Grand Dukes of Tuscany.

Francis soon returned to the attack and at one time even challenged the older Charles to a duel. To Francis’ surprise, Charles accepted to keep his honor, but both monarchs looked for a face-saving way out. On the appointed morning, Charles (left) arrived at the field of honor, “couldn’t find” Francis, and went home, declaring himself the winner. That afternoon, Francis (right) showed up at an “empty field” and likewise declared himself the winner. To be fair to both sides, clocks weren’t too accurate back then.

In 1551, another war, called the Italian War, broke out between the Hapsburgs and the French, who were allied with the Ottoman Turks. During this war, the Turks were able to ravage the coasts of Italy, while the French and Hapsburgs wore each other out in indecisive fighting. The war finally petered out after both the French and Spanish monarchies defaulted on their loans in 1557, leading to the Treaty of Cateau-Cambresis two years later. Both monarchs were also facing growing struggles with Protestants in their lands. The main result of these wars was to confirm Spanish dominance of Italy through control of Naples, Sicily, Milan, and Sardinia, a dominance that would last almost to 1800.

I may be your uncle, but I'm also your second cousin once removed and your sister: The Hapsburg family

The Hapsburg family tree is the classic example of how marriage alliances could build an empire. It could also serve as a poster child for the dangers of inbreeding, a common practice to prevent splitting up family lands. It started with two crucial marriages: that of Ferdinand of Aragon to Isabella of Castile which united Spain, and the union between the Holy Roman Emperor Maximilian and Mary, the daughter of Charles the Bold of Burgundy, which brought the Low Countries under Hapsburg control.

In 1496, largely in reaction to French aggression in Italy, the Hapsburg prince, Philip “the Handsome”, married Joanna “the Mad” of Spain. Their son the emperor Charles V (Charles I of Spain) would inherit Spain, the Holy Roman Empire, the Two Sicilies, the Low Countries, and the growing American Empire.

At this point, the inbreeding fun really began, as Charles married his first cousin, Isabella of Portugal, whose son and heir was Philip II of Spain. Philip would marry Anne of Austria, his niece/first cousin once removed, while his sister, Maria, married her first cousin, the emperor Maximilian II of Germany.

Their son, Philip III of Spain followed suit by marrying his first cousin once removed, Maria Anna of Austria. Their son, Philip IV married his niece/2nd cousin once removed, another Maria Anna of Austria.

Their son, Charles II (above), was so inbred that the first Maria Anna was both his grandmother and aunt. He was descended from his great-great-great-grandmother, Joanna the Mad, along 14 different lines of descent. She was:

- 2 of Charles' 16 great-great-great-grandmothers,
- 6 of his 32 great-great-great-great-grandmothers, and
- 6 of his 64 great-great-great-great-great-grandmothers.

Five generations back he should have had 32 separate ancestors. He had ten.

No wonder Charles couldn't talk until he was four or walk until he was eight. He also drooled, couldn't chew because of a jaw deformity, or talk intelligibly due to an oversized tongue. Because of his infirmities he didn't go to school or allow himself to be cleaned regularly. The one thing he liked to do was shoot guns.

He did manage to live to the age of 39, reigning (though not ruling) for 35 of those years, during which the rest of Europe anxiously waited for him to die so they could carve up the extensive Spanish Empire.

He seems to have taken only one decisive action in his life, and it was a fateful one. Just to spite everyone else who had agreed on how to divide his empire, he wrote a will leaving it to a French cousin, Louis XIV's great-grandson, Philip, probably knowing no one else would allow France to add such a huge empire to its already extensive domains. As expected, when Charles finally died in 1700, the War of the Spanish Succession broke out and would rage for thirteen years until the exhausted combatants would finally come to a compromise agreement.

GEOGRAPHY AND THE RISE OF WESTERN EUROPE SINCE 1500 C.E.

Introduction. The four centuries since 1500 would see the meteoric rise of Western Europe from a cultural backwater to the first culture to dominate the planet. Given Western Europe's tiny size, the question arises: what singled it out as the civilization to rise to global dominance? A century ago, Europeans would attribute their dominance to the moral and religious superiority of European and Christian culture. However, life and history are not quite so simple. Rather, there was a unique combination of forces that converged at the right time and place to make European civilization the culture that would largely define the modern world, especially in terms of its technology and political ideologies.

On the surface, other civilizations seemed more likely to predominate, having larger populations, strongly centralized governments, wealth, and technologies comparable to, if not greater than, Western Europe's. For example, Ming China had a population two to three times that of Western Europe. Traditionally, Chinese technology had been among the most innovative in the world, heavily influencing Europe itself with such inventions as gunpowder, the clock, paper, and the compass. China's government was strongly centralized and autocratic, being run by what was probably the best civil service in the world at that time.

The other major civilizations in the world, such as the Ottoman Turks, Mughal India, Tokugawa Japan, Muscovite Russia, and the Incan and Aztec Empires in the Western Hemisphere, told a similar story of being populous, wealthy (except for Russia), and highly centralized under strong autocratic rulers. In fact, it was Western Europe's *lack* of autocratic rulers that would be the key to its leaping ahead of the pack. For, while the absolute rulers outside of Europe tended to exploit and suppress their middle classes and, in the process, stifle inventiveness and initiative, the spirit of free enterprise and inventiveness had much more free rein in Western Europe. That freedom created a powerful dynamic that allowed Europeans to forge ahead with new ideas, business techniques, and technologies that would shape the modern world. And if freedom

was the key to Europe's success, geography was much of its underlying basis.

Europe's geography and its effects. There were two main geographic factors that would help lead to Western Europe's later dominance. First, Western Europe was broken up by mountains, forests, and bodies of water: the Alps and Pyrenees cutting Italy, Spain, and Portugal off from northern Europe; the English Channel cutting England off from the continent; and the Baltic Sea separating Scandinavia from the rest of Europe in the south. This broke Western Europe into a large number of independent states that no one ruler had the power and resources to conquer and hold. Second, Western Europe had a wide diversity of climates, resources, and waterways that promoted a large number of separate economies, but which were linked together for trade by the extensive coastlines and river systems covering the region. Therefore, just as no one power could control all of Europe politically, no one power could monopolize one vital aspect of its economy. Thus Europe was characterized by what we call *political and economic pluralism*, which also reinforced each other.

Political and economic pluralism also combined to promote the rise of a prosperous and innovative middle class that could create and spread new ideas, business techniques, and technology if the local rulers would allow it. If they did not allow it, there was always the option of moving to another state that did give them the freedom to pursue their interests. The results of such moves, such as when the French Protestant Huguenots left France *en masse* to avoid Louis XIV's religious persecution in 1685, were to deprive the economies of the persecuting nations of some of their wealthiest and most innovative people while boosting the economies of the countries that took these immigrants in. As a result, the balance of power would constantly shift away from powerful and repressive states and in favor of the more progressive and free thinking ones, thus reinforcing political pluralism in Western Europe.

The rise of a free middle class had two other important effects. First of all, in conjunction with Western Europe's political pluralism, it could spread new technology (e.g., the printing press) and ideas (e.g., the Reformation). Second, in conjunction with Western Europe's economic pluralism, the

middle class was able to create a freer capitalist economy and promote a competitive spirit that encouraged new technologies and generated profits for those with the drive and imagination to invent and sell them.

These two factors combined to generate even more rapid technological development, especially in the realm of military inventions. There were three main areas of military technology developed. First of all there was the new gunpowder technology which, when combined with the Roman drill and march recently rediscovered and revived during the Renaissance, created the most powerful and efficient armies in the world by the late 1600's. The defensive response to gunpowder gave Europe the second military factor: stronger and more sophisticated fortresses to resist artillery. These fortresses tied invading armies down to prolonged and tedious sieges that stopped, or at least drastically slowed, the progress of invading armies. One side effect of this was that it fed back into and further reinforced Western Europe's political pluralism. The third military innovation (or more properly, application of peaceful technology to military purposes) was the development of large bulky ships to withstand long voyages over the rough waters of the Atlantic Ocean. Such ships also served as excellent gun platforms, thus making European navies the most deadly on the planet.

These three factors, small but well armed and disciplined armies and navies plus strong fortresses, helped Western Europe establish large overseas colonial empires. As Western Europe's technology progressed over time, its armies would show an amazing ability to defeat non-European armies many times their size with astounding regularity, each time increasing and strengthening their hold on their colonies.

Europe's large colonial empires brought an influx of money and resources into Europe. This fed back into Europe's economic and political pluralism, especially after 1600 when smaller states such as England and the Dutch Republic were taking their share of overseas trade and colonies, thus starting the cycle all over again. These colonial empires also made Western Europe the center of a world economy, providing it with the money and resources needed for the Industrial Revolution in the late 1700's. It is no accident that the Industrial

Revolution started in Great Britain, which also happened to be the foremost colonial power of its day.

Thanks to this cycle, Europe and European derived cultures (e.g., the United States, Canada, and Australia) were able to control 85% of the globe by 1900. Since then, Europe has lost its colonial empire, thanks primarily to two highly destructive world wars, but not before it could spread its ideas and technology across the globe where they have taken firm root.

Maurice of Nassau & the Roman Drill-&March

It was Maurice of Nassau whose adoption of the Roman drill-and-march helped transform European armies into the most effective fighting forces on the planet. The problem he solved was how to get a faster rate of fire despite the long time it took to load the matchlock musket. The solution, based on the ancient Romans, was two-fold. First, Maurice adapted the Roman counter-march whereby fresh troops could move up through gaps in the line to replace their comrades in front. The troops in back could now reload and be ready to fire by the time it was their turn to fire again. By constantly rotating his musketeers in this manner, Maurice's troops could maintain a rate of fire three times that of their opponents.

Second, Maurice adopted the Roman drill-and-march. By constantly drilling his troops in the countermarch and reloading their muskets, they could function like virtual automatons on the battlefield. This had a second, possibly more significant effect. The constant rhythm and cadence of the drill-and-march stimulated a pleasure center in the inner ear that likes a beat. This, in turn, created a psychological bond between men in the ranks. This proved to be powerful glue holding together European

armies and giving them a decisive edge over non-Western armies in the coming centuries.

In 1757, the British general, Robert Clive, showed it wasn't just Europeans who could use these techniques. Leading a small army consisting mostly of European trained and equipped Indian troops, he decisively defeated an Indian army twelve times its size at Plassey, showing the effectiveness of the European drill-and-march. Even today, when close order marching on the battlefield would be suicidal, it still is extensively used in basic training to forge today's modern armies.

In the spirit of the Renaissance, rulers also tried to emulate the Roman legions of antiquity by such measures as laying camps out in an organized grid. Francis I of France even tried to raise 7 regional legions each with 6,000 conscripts.

Su Tzu and the Chinese Drill-and-March

There is evidence of parallel development of the drill-and-march in China as far back as 500 B.C.E., the first drill instructor being none other than Sun Tzu (above), the author of "The Art of War." Working for King Helu of Wu, he supposedly demonstrated his methods' effectiveness by training a contingent of 180 palace women in close order drill with pole arms.

Sun Tzu organized the women into two units, with the king's two favorite concubines as leaders, and gave them basic instructions on moving right, left, about face, etc. When the women did not follow his orders, and laughed instead, he beheaded their unit leaders, which adjusted their attitude appropriately. Having trained them to a peak of efficiency Sun Tzu presented them to the king saying they were properly drilled and disciplined and ready to go

through fire and water for him. Although depressed by losing his two favorite concubines, Helu retained the services of Sun Tzu, who trained Wu's armies and led them to victory over its archrival, Chu.

However, China did not institutionalize the drill and march like the Romans did, since they came to rely more on cavalry to meet the nomads from the North, and horses don't march well.

Fortresses and Sieges in the Early Modern Era

The Dutch fortress of s'Hertengobosch, showing how waterways could be incorporated into fortress defenses

The first response to gunpowder's destructive power was to strengthen existing medieval fortifications. Along with bolstering the old towers, a low wall level with the moat might be built as a stable firing platform for cannons.

In the late 1400s, the Italians developed angled bastions that jutted out from the wall and provided flanking fire covering the entire face of the intervening wall. Artillery posted on the side of the bastions was also relatively safe from the direct fire of the besiegers' guns. The wide platforms at the tops of the bastions allowed defenders to post additional artillery. Fortifications were also built at a sloping angle to minimize damage from enemy artillery, making it harder to hit the walls at a direct perpendicular angle.

A siege was largely a race against time, with the attackers needing to take a fortress before combat, desertion, and especially disease had decimated their ranks, their supplies ran out, and/or an army showed up to relieve the defenders. Therefore, over time, defenders

added different types of fortifications, such as triangular structures known as *ravelins*, in front of the moat to further delay the besiegers' progress and ensure their own survival.

Probably the best-known military engineer of the early modern era was the Marquis de Vauban (1633-1707) who ringed France with a network of 37 fortresses while upgrading the fortifications of some 300 towns and cities for Louis XIV. Besides being an expert at building forts, Vauban was equally adept at besieging and breaking through them.

Along with continuous artillery bombardments to blow breaches in fortress walls, armies used the strategy of undermining. This involved digging a tunnel underneath a section of the wall and then collapsing the tunnel with explosives to bring down the wall overhead now that it was partially unsupported underneath. If defenders detected the mine being dug, they might dig a countermine to meet it before it reached the wall and collapse it. Sometimes this would lead to battles beneath the earth in areas only two or three feet tall and wide.

If the wall were breached, defenders put up an especially ferocious fight against any assaults, because if the city fell, the attackers, usually brutal mercenaries who had just endured the hardships of an extended siege, were typically allowed three days of murder, rape, and pillage. This often encouraged a negotiated surrender by towns to avoid such a fate. Conversely, the attackers knew the defenders would be especially fierce in defending their town and were often hard to induce to make the final assault.

An invading army had to take, or at least isolate by siege, each fortress in its path before proceeding deeper into enemy territory. Not doing so would expose its lines of supply and communications to attack, leaving it isolated in enemy territory.

THE AGE OF EXPLORATION (c.1400-1550)

Introduction. In 1400 A.D. Europeans probably knew less of the globe than they had during the Pax Romana. Outside of Europe and the Mediterranean, little was known, with rumor and imagination filling the gaps. Pictures of Cyclopes and people with dogs' heads or ears the size of satellite dishes illustrated books about lands to the East. There was the legendary Christian king, Prester John with an army of a million men and a mirror that would show him any place in his realm whom Christians hoped to ally with against the Muslims.

Europeans also had many misconceptions about the planet outside their home waters. They had no real concept of the size or shape of Africa or Asia. Because of a passage in the Bible, they thought the world was seven-eighths land and that there was a great southern continent that connected to Africa, making any voyages around Africa to India impossible since the Indian Ocean was an inland sea. Nor had they any idea of the existence of the Americas, Australia, or Antarctica. They also vastly underestimated the size of the earth by some 5-10,000 miles, a miscalculation that gave explorers like Columbus and Magellan the confidence to undertake voyages to the Far East, since they should be much shorter and easier than they turned out to be.

Factors favoring Europe. However, about this time, European explorers started to lead the way in global exploration, timidly hugging the coasts at first, but gradually getting bolder and striking out across the open seas. There were three main factors that led to Europeans opening up a whole new world at this time.

1) *The rise of towns and trade along with the Crusades* in the centuries preceding the age of exploration caused important changes in Europeans' mental outlook that would give them the incentive and confidence to launch voyages of exploration in three ways. First, they stimulated a desire for Far Eastern luxuries. Second, they exposed Europeans to new cultures, peoples and lands, spurring an interest in the outside world that was further stimulated by the travels of Marco Polo in the late 1200's.

Third, towns and the money they generated helped lead to the Renaissance that changed Europeans' view of themselves and the world. There was an increasing emphasis on *secular* topics, including geography. *Skepticism* encouraged people to challenge older geographic notions. *Humanism* and *individualism*, gave captains the confidence in their own individual abilities to dare to cross the oceans with the tiny ships and primitive navigational instruments at their disposal.

2) *Medieval religious fervor* also played its part. While captains such as Columbus, da Gama, and Magellan had to rely on their own skills as leaders and navigators, they also had an implicit faith in God's will and guidance in their missions. In addition, they felt it their duty to convert any new peoples they met to Christianity. Thus we see Renaissance Europe caught in the transition between the older medieval values and the new secular ones. Together they created a dynamic attitude that sent Europeans out on a quest to claim the planet as their own.

3) *Europe's geographic position* also drove it to find new routes to Asia in three ways. First of all, Europe's geographic position at the extreme western end of the trade routes with the East allowed each of the numerous middlemen to take his cut and raise the cost of the precious silks and spices before passing them on to still another middleman. Those trade routes were long, dangerous, and quite fragile. It would take just one strong hostile power to establish itself along these routes in order to disrupt the flow of trade or raise the prices exorbitantly. For Europeans, that power was the Ottoman Empire. The fall of the Byzantine Empire and the earlier fall of the crusader states had given the Muslims a larger share of the trade headed for Europe. Thus Europe's disadvantageous geographic position provided an incentive to find another way to the Far East.

However, Europe was also in a good position for discovering new routes to Asia. It was certainly in as good a position as the Muslim emirates on the coast of North Africa for exploring the Atlantic coast of Africa. And when Spain gained control of both sides of the straits of Gibraltar, it was in a commanding position to restrict any traffic passing

in and out of the Western Mediterranean. Europe was also well placed for exploration across the Atlantic Ocean.

Finally, ships and navigation technology had seen some dramatic leaps forward. The most striking of these was the compass, which had originated in China around 200 B.C. This allowed sailors to sail with much greater certainty that they were going in the right direction. Instruments such as the quadrant, crosstaff, and astrolabe allowed them to calculate latitude by measuring the elevation of the sun and North Star, although the rocking of ships at sea often made measurements taken with these instruments highly inaccurate. Columbus, one of the best navigators of his day, took readings in the Caribbean that corresponded to those of Wilmington, North Carolina, 1100 miles to the north! As a result of such imperfect measurements, sailing directions might be so vague as to read: "Sail south until your butter melts. Then turn west." Compounding this was the lack of a way to measure longitude (distance from east to west) until the 1700's with the invention of the chronometer.

Maps also left a lot to be desired. A medieval map of the world, showing Jerusalem in the center and Paradise to the Far East, gives an insight into the medieval worldview, but little useful geographic information. By 1400, there were fairly decent coastal maps of Europe and the Mediterranean, known as *portolan charts*. However, these were of no use beyond Europe, and larger scale global projections would not come along until the 1500's. As a result, explorers relied heavily on sailors' lore: reading the color of the water and skies or the type of vegetation and sea birds typical of an area. However, since each state jealously guarded geographic information so it could keep a monopoly on the luxury trade, even this information had limited circulation.

Advances in ship design involved a choice between northern Atlantic and southern Mediterranean styles. For hulls, shipwrights had a choice between the Mediterranean *carvel built* design, where the planks were cut with saws and fit end to end, or northern *clinker built* designs, where the planks were cut with an axe or adze and overlapped. Clinker-built hulls were sturdy and watertight, but limited in size to the length of one

plank, about 100 feet. As a result, the southern carvel built hulls were favored, although they were built in the bulkier and sturdier style of the northern ships to withstand the rough Atlantic seas. One other advance was the stern rudder, which sat behind the ship, not to the side. Unlike the older side steering oars which had a tendency to come out of the water as the ship rocked, making it hard to steer the ship, the stern rudder stayed in the water.

There were two basic sail designs: the southern triangular, or *lateen*, (i.e., Latin) sail and the northern square sail. The lateen sail allowed closer tacking into an adverse wind, but needed a larger crew to handle it. By contrast, the northern square sail was better suited for tailwinds and used a smaller crew. The limited cargo space and the long voyages involved required as few mouths as possible to feed, and this favored the square design for the main sail, but usually with a smaller lateen sail astern (in the rear) to fine tune a ship's direction. Also, once sailors had figured out how to exploit prevailing easterlies and westerlies (known as trade winds) so they usually had tail winds, they could rely more on square sails as their primary means of propulsion.

The resulting ship, the *carrack*, was fusion of northern and southern styles. It was carvel built for greater size but with a bulkier northern hull design to withstand rough seas. Its main sail was a northern square sail, but it also used smaller lateen sails for tacking into the wind.

Living conditions aboard such ships was appalling, especially during long voyages. Ships were filthy, with little or no sanitation facilities. They constantly leaked and were crawling with rats, lice, and other creatures. Without refrigeration, food and water spoiled quickly and horribly. Disease was rampant, especially scurvy, caused by vitamin C deficiency. A *good* voyage between Portugal and India would claim the lives of twenty per cent of the crewmen from scurvy alone. It should come as no surprise then that ships' crews were often drawn from the dregs of society and required a strong and often brutal hand to keep them in line.

Portugal and Spain led the way in early exploration for two main reasons. First, they were the earliest European recipients of Arab math, astronomy, and

geographic knowledge based on the works of the second century C.E. geographer, Ptolemy. Secondly, their position on the southwest corner of Europe was excellent for exploring southward around Africa and westward toward South America.

Portugal and the East (c.1400-1498). Portugal started serious exploration in the early 1400's, hoping to find both the legendary Prester John as an ally against the Muslims and the source of gold that the Arabs were getting from overland routes through the Sahara. At first, they did not plan to sail around Africa, believing it connected with a great southern continent. The guiding spirit for these voyages was Prince Henry the Navigator whose headquarters at Sagres on the north coast of Africa attracted some of the best geographers, cartographers and pilots of the day. Henry never went on any of his expeditions, but he was their heart and soul.

The exploration of Africa offered several physical and psychological obstacles. For one thing, there were various superstitions, such as monsters, Cape Bojador, which many thought was the Gates of Hell, and boiling seas as one approached the equator. Also, since the North Star, the main nighttime navigational guide, would disappear south of the Equator, sailors were reluctant to cross that line.

Therefore, early expeditions would explore a few miles of coast and then scurry back to Sagres. This slowed progress, especially around Cape Bojador, where some fifteen voyages turned back before one expedition in 1434 finally braved its passage without being swallowed up. In the 1440's, the Portuguese found some, but not enough, gold and started engaging in the slave trade, which would disrupt African cultures for centuries. In 1445, they reached the part of the African coast that turns eastward for a while. This raised hopes they could circumnavigate Africa to reach India, a hope that remained even when they found the coast turning south again.

When Prince Henry died in 1460, further expeditions stalled for the next 20 years. However, French and English interest in a route around Africa spurred renewed activity on Portugal's part. By now, Portuguese captains were taking larger

and bolder strides down the coast. One captain, Diego Cao, explored some 1500 miles of coastline. With each such stride, Portuguese confidence grew that Africa could be circumnavigated. Portugal even sent a spy, Pero de Covilha, on the overland route through Arab lands to the Indies in order to scout the best places for trade when Portuguese ships should finally arrive.

The big breakthrough came in 1487, when Bartholomew Dias was blown by a storm around the southern tip of Africa (which he called the Cape of Storms, but the Portuguese king renamed the Cape of Good Hope). When Dias relocated the coast, it was to his west, meaning he had rounded the tip of Africa. However, his men, frightened by rumors of monsters in the waters ahead, forced him to turn back. Soon after this, the Spanish, afraid the Portuguese would claim the riches of the East for themselves, backed Columbus' voyage that discovered and claimed the Americas for Spain. This in turn spurred Portuguese efforts to find a route to Asia before Spain did. However, Portugal's king died, and the transition to a new king meant it was ten years before the Portuguese could send Vasco da Gama with four ships to sail to India. Swinging west to pick up westerly trade winds, da Gama rounded the Cape of Good Hope in three months, losing one ship in the process. Heading up the coast, the Portuguese encountered Arab surprise and hostility against European ships in their waters. However, da Gama found an Indian pilot who led the Portuguese flotilla across the Indian Ocean to India in 1498.

The hostility of the Arab traders who dominated trade with India and the unwillingness of the Indians to trade for European goods, which they saw as inferior, made getting spices quite difficult. However, through some shrewd trading, da Gama managed to get one shipload of spices and then head home in August 1498. It took over a year, until September 1499, to get back to Portugal, but he had proven that Africa could be circumnavigated and India could be reached by sea. Despite its heavy cost (two of four ships and 126 out of 170 men) Da Gama's voyage opened up new vistas of trade and knowledge to Europeans.

Subsequent Portuguese voyages to the East reached the fabled Spice Islands (Moluccas) in 1513. In that same year, the Portuguese explorer,

Serrao, reached the Pacific at its western end while the Spanish explorer, Balboa, was discovering it from its eastern end. Also in 1513, the Portuguese reached China, the first Europeans to do so in 150 years. They won exclusive trade with China, which had little interest in European goods. However, China was interested in Spanish American silver, which made the long treacherous voyage across the Pacific to the Spanish Philippines. There, the Portuguese would trade Chinese silks for the silver, and then use it for more trade with China, while the Spanish would take their silks on the even longer voyage back to Europe by way of America. In 1542, the Portuguese even reached Japan and established relations there. As a result of these voyages and new opportunities, Portugal would build an empire in Asia to control the spice trade.

Spain and the exploration of the West (1492-c.1550). Spain led the other great outward thrust of exploration westward across the Atlantic Ocean. Like Portugal, the Spanish were also partially driven in their explorations by certain misconceptions. While they did realize the earth is round, they also vastly underestimated its size and thought it was seven-eighths land, making Asia much bigger and extending much further west. Therefore, they vastly underestimated the distance of a westward voyage to Asia.

This was especially true of a Genoese captain, Christopher Columbus, an experienced sailor who had seen most of the limits of European exploration up to that point in time, having sailed the waters from Iceland to the African coast. Drawing upon the idea of a smaller planet mostly made up of land, Columbus had the idea that the shortest route to the Spice Islands was by sailing west, being only some 3500 miles. In fact, the real distance is closer to 12,000 miles, although South America is only about 3500 miles west of Spain, explaining why Columbus thought he had hit Asia. The problem was that most people believed such an open sea voyage was still too long for the ships of the day.

Getting support for this scheme was not easy. The Portuguese were already committed to finding a route to India around Africa, and Spain was preoccupied with driving the Moors from their last stronghold of Granada in southern Spain.

However, when the Portuguese rounded the Cape of Good Hope and stood on the verge of reaching India, Spain had added incentive to find another route to Asia. Therefore, when Granada finally fell in 1492, Spain was able to commit itself to Columbus' plan.

Columbus set sail August 3, 1492 with two caravels, the *Nina* and *Pinta*, and a carrack, the *Santa Maria*. They experienced perfect sailing weather and winds. In fact, the weather was too good for Columbus' sailors who worried that the perfect winds blowing out would be against them going home while the clear weather brought no rain to replenish water supplies. Columbus even lied to his men about how far they were from home (although the figure he gave them was fairly accurate since his own calculations overestimated how far they had gone). By October 10, nerves were on edge, and Columbus promised to turn back if land were not sighted in two or three days. Fortunately, on October 12, scouts spotted an island, possibly San Salvador, which Columbus mistook for Japan.

After failing to find the Japanese court, Columbus concluded he had overshot Japan. Further exploration brought in a little gold and a few captives. But when the *Santa Maria* ran aground, Columbus decided to return home. A lucky miscalculation of his coordinates caused him to sail north where he picked up the prevailing westerlies. The homeward voyage was a rough one, but Columbus reached Portugal in March 1493, where he taunted the Portuguese with the claim that he had found a new route to the Spice Islands. This created more incentive for the Portuguese to circumnavigate Africa, which they did in 1498. It also caused a dispute over who controlled what outside of Europe, which led to the pope drawing the Line of Demarcation in 1494.

Ferdinand and Isabella, although disappointed by the immediate returns of the voyage, were excited by the prospects of controlling the Asian trade. They gave Columbus the title "Admiral of the Ocean Sea, Viceroy and Governor of the Islands that he hath discovered in the Indies." Over the next decade, they sent him on three more voyages to find the Spice Islands. Each successive voyage put even more of the Caribbean and surrounding coastline on the map, but the Spice Islands were

never found. Columbus never admitted that his discovery was a new continent. He died in 1504, still convinced that he had reached Asia.

However, by 1500, many people were convinced that this was a new continent, although its size and position in relation to and distance from Asia were by no means clear. The Portuguese discovery of a route to India around Africa in 1498 provided more incentive for Spanish exploration. In 1513, the Spanish explorer, Balboa discovered the Pacific Ocean, having no idea of its immensity or that the Portuguese explorer, Serrao, was discovering it from the Asian side. Given the prevailing view of a small planet, many people thought that the Pacific Sea, as they called it, must be fairly small and that Asia must be close to America. Some even thought South America was a peninsula attached to the southern end of Asia. Either way, finding a southwest passage around the southern tip of South America would put one in the Pacific Sea and a short distance from Asia. If this were so, it would give Spain a crucial edge over Portugal, whose route around Africa to India was especially long and hard.

In 1519, Charles V of Spain gave five ships and the job of finding a southwest passage around South America to Ferdinand Magellan, a former Portuguese explorer who had been to the Spice Islands while serving Portugal. Magellan's circumnavigation of the globe was one of the great epic, and unplanned, events in history. After sailing down the South American coast, he faced a mutiny, which he ruthlessly suppressed, and then entered a bewildering tangle of islands at the southern tip of the continent known even today as the Straits of Magellan. Finding his way through these islands took him 38 days, while the same journey today takes only two.

Once they emerged from the Straits of Magellan into the Pacific "Sea", Magellan and his men figured they were a short distance from Asia, and set out across the open water and into one of the worst ordeals ever endured in nautical history. One of those on the journey, Pigafetta, left an account of the Pacific crossing:

"On Wednesday the twenty-eighth of November, one thousand five hundred and twenty, we issued forth from the said strait and

entered the Pacific Sea, where we remained three months and twenty days without taking on board provisions or any other refreshments, and we ate only old biscuit turned to powder, all full of worms and stinking of the urine which the rats had made on it, having eaten the good. And we drank water impure and yellow. We ate also ox hides, which were very hard because of the sun, rain, and wind. And we left them...days in the sea, then laid them for a short time on embers, and so we ate them. And of the rats, which were sold for half an ecu apiece, some of us could not get enough.

"Besides the aforesaid troubles, this malady (scurvy) was the worst, namely that the gums of most part of our men swelled above and below so that they could not eat. And in this way they died, inasmuch as twenty-nine of us died...But besides those who died, twenty-five or thirty fell sick of divers maladies, whether of the arms or of the legs and other parts of the body (also effects of scurvy), so that there remained very few healthy men. Yet by the grace of our Lord I had no illness.

"During these three months and twenty days, we sailed in a gulf where we made a good 4000 leagues across the Pacific Sea, which was rightly so named. For during this time we had no storm, and we saw no land except two small uninhabited islands, where we found only birds and trees. Wherefore we called them the Isles of Misfortune. And if our Lord and the Virgin Mother had not aided us by giving good weather to refresh ourselves with provisions and other things we would have died in this very great sea. And I believe that nevermore will any man undertake to make such a voyage."

By this point, the survivors were so weakened that it took up to eight men to do the job normally done by one. Finally, they reached the Philippines, which they claimed for Spain, calculating it was on the Spanish side of the Line of Demarcation. Unfortunately, Magellan became involved in a local tribal dispute and was killed in battle. Taking into account his previous service to Portugal in the East, Magellan and the Malay slave who accompanied him were the first two people to circumnavigate the earth.

By now, the fleet had lost three of its five ships: one having mutinied and returned to Spain, one

being lost in a storm off the coast of South America, and the other being so damaged and the crews so decimated that it was abandoned. The other two ships, *Trinidad* and *Victoria*, finally reached the Spice Islands in November 1521 and loaded up with cloves. Now they faced the unpleasant choice of returning across the Pacific or continuing westward and risking capture in Portuguese waters. The crew of the *Trinidad* tried returning over the Pacific, but gave up and were captured by the Portuguese. Del Cano, the *Victoria's* captain, sailed far south to avoid Portuguese patrols in the Indian Ocean and around Africa, but also away from any chances to replenish its food and water. Therefore, the Spanish suffered horribly from the cold and hunger in the voyage around Africa.

When the *Victoria* finally made it home in 1522 after three years, only 18 of the original 280 crewmen were with it, and they were so worn and aged from the voyage that their own families hardly recognized them. Although the original theory about a short South-west Passage to Asia was wrong, they had proven that the earth could be circumnavigated and that it was much bigger than previously supposed. It would be half a century before anyone else would repeat this feat. And even then, it was an act of desperation by the English captain Sir Francis Drake who was just trying to avoid capture by the Spanish fleet.

Interior and coastal explorations (1519-c.1550). Meanwhile, the Spanish were busy exploring the Americas in search of new conquests, riches, and even the Fountain of Youth. There were two particularly spectacular conquests. The first was by Hernando Cortez, who led a small army of several hundred men against the Aztec Empire in Mexico. Despite their small number, the Spanish could exploit several advantages: their superior weapons and discipline, the myth of Quetzecoatl which foretold the return of a fair haired and bearded god in 1519 (the year Cortez did appear), and an outbreak of smallpox which native Americans had no prior contact with or resistance to. Because of this and other Eurasian diseases, native American populations would be devastated over the following centuries to possibly less than ten per cent their numbers in 1500.

The Spanish conquistador, Pizarro, leading an army of less than 150 men, carried out an even more amazing conquest of the Inca Empire in Peru in the 1530's. Thanks to a smallpox outbreak, which had preceded him and taking advantage of dispute over the throne, Pizarro captured the Inca Emperor, whose authority was so great that his capture virtually paralyzed the Incas into inaction. As a result, a highly developed empire ruling millions of people fell to a handful of Spaniards.

The conquests of Mexico and Peru more than compensated Spain for its failure to establish a trade route to the Spice Islands. The wealth of South America's gold and silver mines would provide Spain with the means to make it the great power of Europe in the 1500's. Unfortunately, Spain would squander these riches in a series of fruitless religious wars that would wreck its power by 1650.

Other Spanish expeditions were exploring South America's coasts and rivers, in particular the Amazon, Orinoco, and Rio de la Plata, along with ventures into what is now the southwest United States (to find the Seven Cities of Gold), the Mississippi River, and Florida (to find the Fountain of Youth). While these found little gold, they did provide a reasonable outline of South America and parts of North America by 1550. However, no one had yet found an easy route to Asia. Therefore, the following centuries would see further explorations which, while failing to find an easier passageway, would in the process piece together most of the global map.

A Short History of the World Map to 1400

The early Greeks, such as Homer, saw the world as a disc surrounded by Ocean (above). If you sailed beyond the Pillars of Hercules (Straits of Gibraltar) you would fall off. By 500 B.C.E., although the Greeks still thought the land mass of Europe, Asia, and Africa was surrounded by Ocean, more and more of them were coming to the conclusion that the world was spherical, as evidenced by ships

disappearing over the horizon and the shadow of the earth on the sun. While most educated people believed the world was round, one exception was a Greek geographer of the 5th century C.E., Cosmas Indicopleustes, who said the world must be flat, because if it were round, people in the Southern Hemisphere would have fallen off.

The most influential geographer of antiquity was the 2nd century C.E. Greek geographer, Ptolemy, who envisioned a round world, but one that was mostly land. Included in this was a Great Southern Continent that was considered necessary to balance all the land in the Northern Hemisphere so the globe didn't tip over. It was Ptolemy's map (below) that the Arabs passed to the Spanish and Portuguese, giving the impression that the earth was smaller than it really is, that Asia stretched 3,000 miles further east than it does and that a Great Southern Continent joined with Africa and Asia to make the Indian Ocean an inland sea. Together these left the conclusion that a voyage around Africa might be impossible, while one going west from Europe should reach Asia fairly easily.

Luckily, Ptolemy's figures ignored the remarkable work of another Greek, Eratosthenes, who through some astute geometry had calculated the earth's circumference to within 50 miles of its real size. I say luckily, because if sailors had known the earth's real size, it would have taken much longer for them to get the courage and technology to make transoceanic voyages.

Among the things lost in the West with the fall of Rome was Ptolemy's world map. Replacing it was the T-in-O map showing a large blob of

land (Asia) over two smaller blobs of land (Europe and Africa), which were divided in the middle by three other blobs (the Mediterranean Sea and the Don and Nile Rivers) that formed a T. Surrounding all this was the Ocean, which made the O in the T-in-O map. Orientation of medieval European maps had the East on top, since that was where Paradise was thought to be. And, of course, Jerusalem was at the center of the map. No wonder so many explorers got lost.

Marco Polo

Marco Polo was by no means the first European to reach China. However, he is particularly remembered because of his account of his travels, which included spending 17 years in China, some of them as a governor of a city for the Mongol ruler, Kublai Khan. (The Mongols favored foreign officials over their Chinese subjects, whom they didn't trust.)

Upon returning to his native Venice, Marco was captured in a war with another Italian city-state, Genoa. While in prison, he recounted his travels to a fellow prisoner, Rustichelli, who wrote them down and published them. It was a best seller for its time and sparked increased interest in exploration. Much like Herodotus, Marco's descriptions of things and places he actually saw are fairly reliable. However, sights reported to him second or third hand (such as people with faces in their stomachs, arms growing out of their ears, and umbrella-feet to protect them against the sun) are typically taken at face value and are often of questionable value.

And there were some weird things, too...like monsters, boiling seas, and possibly the strangest of all...the platypus.

Nature's Cruellest Joke: the Duckbill Platypus
Among the most ridiculous legends, if not an outright hoax, was the supposed existence of a mammal with a duckbill, webbed feet, and a beaver's tail. Reasonable people quickly pointed out that if such a creature did indeed exist, it was nature's cruelest joke. When the discovery of the platypus was announced back

in Europe, people thought it was a practical joke or delusion. In fact, even the first European to discover it in 1799, Dr. George Shaw, thought it was a hoax and cut it open expecting to find stitches holding the bill to the skin. One of the legends surrounding the so-called platypus was that its young had teeth and lost them in favor of ridges for scrounging through river mud for food!!!

Added to this ridiculous rumor was the idea that the platypus will only mate in captivity if it has river mud full of yummy bugs, etc. to feed on. Not satisfied with such absurd claims, these hoaxsters further claimed that, although a mammal, THE PLATYPUS LAID EGGS!!

Another of the improbable legends surrounding the platypus was belief in a venomous hind leg as its primary defense!!!

And, of course, all this was true.

Some other “platyfacts”:

- The accepted plural for platypus is either platypus or platypuses. Platypi is *not* a recognized form. Also, contrary to popular belief, the proper term for a baby platypus is not puggle.
- According to aboriginal legends, the first platypus was born when a very persuasive water rat convinced a duck to mate with him. Boy was her mother mad 9 months later.
- The adult platypus is only about half the size of a house cat and lives about 12 years.
- Female platypus don't have nipples, but secrete milk through two patches of skin on their abdomen that the baby platypus, which at birth is the size of a lima bean, slurps up.

The Legendary Kingdom of Prester John

Prester John was one of the most enduring legends of the middle ages. In 1165 a letter supposedly from him showed up in Europe, claiming he had a huge Christian kingdom in Central Asia and wanted to join Christian Europe in crushing the Muslims in between. Other legends surrounding him reported that he was descended from one of the Three Wise Men and had a magic mirror that would let him see any part of his realm he wanted. While most of his army of one million soldiers were naked, their leaders wore armor made from alligator hides.

It gets better, because his kingdom bordered the earthly paradise and contained such wonders as unicorns, griffins, the Fountain of Youth, men with three horns coming out of their foreheads or eyes in the backs of their heads, a waterless sea full of fish, and Amazons and pygmies who each year allied in a war against the giant birds.

Indeed, there were Nestorian Christians in Central Asia that could have formed a germ of truth for this legend. Similarly, the Christian kingdom of Abyssinia in Africa was another source for the legend and a goal for Portuguese explorers to find.

Where the original letter came from is another mystery, although recent scholarship suggests it may have been somewhere in Northern Italy, possibly of Hebrew origin. This raises the tantalizing question of whether it was an intentional hoax designed to lead European explorers on a wild goose chase for several centuries. If that was the case, it worked marvelously.

The Technology of Navigation

While primitive by our standards, navigational instruments and techniques sailors during the age of exploration did a remarkable job of helping sailors find their way to new places and back home again. The most notable piece of navigational technology was the compass.

The first mention of the compass being used by the Chinese for navigation was in 1117 C.E. While previously believed that Europe got the compass indirectly from China, its earliest recorded use in Europe was in 1187, even before

its first mention in Arab sources, who presumably would have been the middlemen passing it on to Europe. Therefore, some historians believe the navigational compass was invented independently in both China and Europe.

Nautical compasses faced the problem of being disrupted by rocking ships. One solution was to place a magnetized needle in a floating straw, the water's fluidity maintaining some stability to compensate for the ship's rocking. Another version was to balance a magnetized needle on one's thumbnail.

Sailors called the compass the constant needle. However, on Columbus' first voyage, which was also the first long distance east-west voyage by Europeans, they noticed the compass pointing toward magnetic north (which they had no clue about) instead of the North Star. Although initially disturbing, this proved to be of no great significance for future voyages.

The crosstaff, quadrant, and astrolabe were all used to measure the elevation of the sun or North Star in order to calculate latitude, the higher the sun or North Star, the lower the latitude. For example, the astrolabe was a circular disc with degrees measured evenly from 0 to 90 from top to bottom. Holding the instrument upright, a pointer hinged at the center would be moved until it lined up with the sun. Where the pointer intersected on the outer edge told the latitude in degrees.

Calculating the ship's speed was done by tossing overboard a piece of wood attached to a rope with knots tied in it at regular intervals. The rope would be let out at the rate of the ship's speed for certain amount of time and then reeled in to count how many knots the ship had traveled. Thus the nautical term knots.

Calculating where the ship had traveled was done with a traverse board. Which had 32 radii, each with 8 pegs to record the direction the ship was sailing each half hour of a pilot's 4-hour shift.

Measuring the water's depth was done with a lead line, a 1200 foot long rope that was knotted at intervals and weighted with a piece of lead hollowed out underneath and filled with tallow. A sailor would drop it overboard, count the knots just above the water and then pull it up to read the debris from the tallow for telltale signs of where they might be.

Finding longitude (one's relative east-west position) was much harder, because there were no constants (such as the North Star) to rely on and two variables to keep track of: the time at home and how far one had traveled out to sea.

People knew the sun moved 15° each hour to travel a full 360° circle in one 24 hour day. Therefore, if they knew what time it was at home, they could measure the angle ACB where A was the sun at the present location, B was the sun's position as it would appear at high noon back home, and C was the ship. That angle should be how many degrees west the ship was.

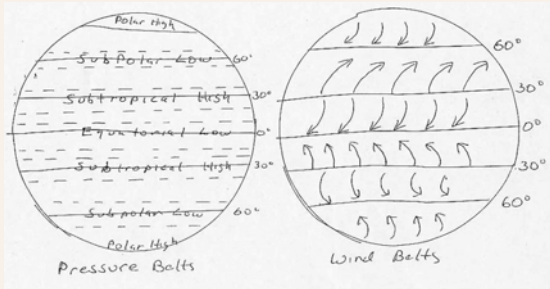

The problem was keeping accurate time so they could know the time back home, since there were no accurate clocks that could work on a rocking ship. They had half-hour glasses to mark time, but if someone was too busy or forgot to change the sandglass, they would lose track of what time it was back home and thus be unable to calculate their longitude. It would not be until the 1750s that John Harrison, after 30 years of trial and error, invented the chronometer, an accurate timepiece that worked on sailing ships, thus making possible the calculation of longitude.

Since the British invented the chronometer, they got to determine the primary reference point for longitude, which was Greenwich, which just happened to be in England.

The trade winds were possibly the single most important thing sailors needed to be aware of

for long-distance voyages. The most basic thing to understand about winds is that all winds blow from high pressure to low pressure. What causes winds is uneven heating of the earth, which creates different belts of air pressure. There are seven major pressure belts between the poles. Moving from the poles to the equator there are two polar high-pressure belts, two sub-polar low-pressure belts, two subtropical high-pressure belts, and the equatorial low-pressure belt.

Therefore, it would seem prevailing trade winds would blow straight north or south between these belts. But they don't, thanks to the spin of the earth and something known as the Coriolis effect. The fly in the ointment is that the earth doesn't spin at the same speed at different latitudes. After all, a point at the equator has to travel over 1000 miles per hour to make a complete rotation in 24 hours. By comparison, a point at 45° north only has to travel half that speed.

Therefore, a wind blowing south toward the equator from 30° is starting at a point that is traveling east at a much slower speed than the point on the equator directly south of it. Thus, when it reaches the equator, it will have fallen behind that much faster moving point, making it blow to the southwest instead of due south. Similarly all winds blowing toward the equator will fall behind and also blow in a northwesterly or southwesterly direction. And all wind blowing away from the equator will be going faster than their corresponding point due north or south and will "jump ahead", blowing in a northeasterly or southeasterly direction.

Although sailors didn't understand what causes winds, they did know where different belts of trade winds were (along with belts of doldrums

with no prevailing winds) and plotted their courses accordingly.

Classified information. Geographic knowledge was kept so secret that when the Dutch wanted to go to the Spice Islands a full century after the Portuguese had gotten there, they still didn't know the route. Luckily for them, a Dutch captain who had been in Portuguese service in the Far East showed them the way.

Ship Construction and Design

Ancient shipwrights used plank first-construction where the planks of the hull were laid first and then strengthened with an infrastructure of ribs and thwarts. This evolved from the earliest ships, which were dugout canoes. To make them larger, planks (AKA strakes) were added up the sides, being bent by heating to conform to the master plan inside the shipwright's head. Since there was no frame to attach the strakes to, they were all joined together by thousands of tenons, a very time-consuming process. As ships grew in size, an interior frame of ribs was needed to reinforce the strakes, and even higher up crossbeams (AKA thwarts) were added. There were no written plans, and so each ship was a unique creation.

By the early medieval period, both cheap labor and timber were in relatively short supply in the Mediterranean. The result was a new type of construction technique known as frame-first, which used pre-conceived plans to build a skeletal frame of ribs to which the planks were then fitted. Also, nails were probably being used to fasten the planks to the frame, a much easier and faster method than fitting the planks together edge-to-edge with the tedious mortis-and-tenon method (below).

However, iron nails were handmade and expensive, so cheaper alternatives were often used, such as wedge shaped wooden dowels

known as a trenails and using rope to tie planks together. Both of these were techniques used for thousands of years.

By the 1400s frame-first construction was in general use in the Mediterranean and making it possible to develop large, sturdy ships, suitable for extended voyages of exploration on rough seas. It soon spread to Northern Europe, replacing the lapstrake (over-lapping) construction, which seriously limited the size of ships they could build.

The Stern rudder was another innovation vital to the voyages of exploration. The older side-mounted steering oars were limited to the calmer waters of the South, since rocking from side to side in rough waters caused it to come out of the water, making it useless. The sternpost rudder invented in the first century in China and probably independently again in the 1300s in Northern Europe was only susceptible to pitching along the length of a ship's beam, which was much less pronounced than rocking from side to side. Any ship pitching violently enough to bring the stern rudder out of the water was probably doomed anyway.

The stern rudder also affected the design of the hull, making the stern (back) more squared off to accommodate it. Sometimes the tiller for operating the rudder was below deck, so its operator had to be told which way to turn.

Ships of the age of exploration. Caravels were lateen rigged vessels that were favored for tacking into the wind. *The lateen sail* could tack 55° into the wind while the square sail could only tack 67°, allowing it to make 50% more progress toward reaching its goal in a given time. Originally a type of fishing vessel, the Portuguese developed and enlarged the caravel for longer voyages to a capacity of 80-100 tons. Two of Columbus' ships, the Nina and Pinta started off as small caravels of about 60 tons.

At times a caravel was converted to a Caravel Redunda by moving the largest mast back to the centre of the ship and refitting it with a square sail. Columbus did this to the "Nina" at the Canary Islands on his way to America. While good for tacking into the wind, lateen sails were hard to handle and required larger crews.

The Santa Maria was a typical small carrack (above), about 75 feet long and 25 feet wide in the beam, with a 6-foot draught. It had 3 masts with 5 sails, the most important being a large square sail, while the others were used for trimming.

Later ships would have increasingly more sails, and the main sails would shrink accordingly. Columbus thought the Santa Maria a mediocre ship and unfit for long-distance exploring. It ran aground on Christmas Day, 1492 and was abandoned. Thus, only the Nina and Pinta, caravels refitted as caravels redundas, made the return voyage.

As a point of comparison, Chinese ships, which Westerners would derisively call junks, were huge and much more sophisticated, having, among other things, separate bulkheads to prevent an entire ship from being swamped by a hole in the hull.

Between 1405 and 1433, the Chinese admiral, Zheng He led seven voyages into the "Western Seas" to trade and collect tribute. After his death in 1433, the Ming court sent no more voyages west, leaving it to the Portuguese to find the way around Africa. His last expedition consisted of 60 ships (as opposed to three for Columbus' first voyage) and explored the east coast of Africa. If the Chinese voyages had continued, they very likely would have "discovered" Europe before the Portuguese had found their way to India.

A Titanic disaster. Speaking of separate bulkheads, modern ships, including the Titanic, have adapted this feature to their ships. The main reason the Titanic sank in 1912 was that the pilot steered it away from a direct hit with the iceberg. Instead, it scraped all along the length of the ship, penetrating most or all of the bulkheads, causing it to sink. A direct hit would have caused a more violent initial jolt, but may have also saved the ship.

Through the “Gates of Hell”: The Portuguese and Africa (c.1400-88)

Prince Henry the Navigator was the guiding spirit of early Portuguese explorations. He established a base at Sagres on the southern tip of Portugal from which he launched voyages to explore Africa’s coast.

Much of the inspiration for Henry’s voyages came from the legendary pilgrimage of Mansa Musa, the king of Timbuktu, to Mecca in 1324. His lavish spending of gold got Europeans interested in the Sub Saharan gold trade. However, since the Arabs controlled the caravan routes over the Sahara to Timbuktu, Henry and the Portuguese thought they might find another route along Africa’s west coast.

Among Henry’s first acts was to take the Madeiras, Azores, and Cape Verde Islands off the west coast of Africa as forward bases for exploration of the continent.

There were various psychological barriers to exploring down the African coast. One legitimate one was that past the equator, sailors would lose sight of their one stable reference point for sailing at night, the North Star. There were also the usual stories of monsters and boiling seas. But the most daunting psychological barrier was Cape Bojador: the Gates of Hell.

There were good reasons for sailors to consider Cape Bojador the Gates of Hell and ends of the earth. For one thing, the coast extends into an underwater reef that makes the water’s depth only six feet out to a distance of three miles from shore, so sailors have to steer clear of land. When waves crash into subsurface gullies in the reef, water spouts up like giant steaming geysers. Adding to the impression of boiling seas is a hissing sound caused by the flicking tails of sardines and the larger fish that feed upon them as they come to the surface.

Furthermore, desert dust blowing out to sea creates an unnatural darkness and heat, all suggestive of Hell to superstitious sailors. Just as disturbing are ferrous rocks that wreak havoc with compasses, causing their needles to whirl erratically. Add to that whirlpools, crumbling cliffs, shifting sands and the large number of ships that attempted the passage never came back, it didn’t take much imagination to add monsters to the mix and scare even seasoned sailors off.

Therefore, the first expeditions down the coast were short & timid. Some 15 different expeditions either never made it back from rounding Cape Bojador or stopped short of it and turned back.

Finally, in 1434 a Portuguese expedition passed Cape Bojador and left the Gates of Hell behind.

Probably the most powerful African kingdom the Portuguese encountered was that of Benin, whose oba (king) could supposedly call on an army of 80,000 men.

Then, in the 1440s, the Portuguese finally found gold. They also discovered another, more insidious source of wealth: the slave trade.

For the next 400 years, millions of Africans would be kidnapped and dragged to the Americas to replace the Native Americans who had died from European diseases and mistreatment. Millions would die on the hideous Middle Passage on ships over packed with human cargo. Millions more would not survive their first years in the New World. And for those who did survive, they and their descendants would suffer generations of brutality, poverty, and humiliation: a legacy that still reverberates today.

In 1445, the Portuguese reached the point where Africa’s coast turns eastward, raising hopes that they might be able to circumnavigate the continent and reach India. Then, in 1460, Prince Henry died, and the expeditions slowed to a crawl.

However, growing English and French interest and presence in these waters led the Portuguese resume their explorations. In 1473 they first crossed the equator and no one spontaneously combusted. After that the voyages became longer and bolder. One explorer, Diego Cao explored 1500 miles of coast

In 1488 a Portuguese expedition led by Bartolomeu Diaz was blown off course by a storm near the southern tip of Africa. When he found the coast again, it was to his west, indicating he had rounded what he called the Cape of Storms, now known by the more optimistic Cape of Good Hope. However, his sailors, scared of monsters, forced him to return home.

It would be 10 years before the Portuguese would return to finish finding the route to India.

The strange journey of Pero da Covilha

In 1487, as Diaz was about to sail south, the Portuguese king, John II, sent two men, Pero da Covilha and Alfonso da Paiva, across the Mediterranean and then the Red Sea to find where cinnamon, other spices, and Prester John could be found. Paiva died, but Covilha sent back a letter advising the Portuguese to navigate the east coast of Africa and proceed to Calicut in India, useful information that Vasco da Gama would use on his epic voyage.

Covilha then proceeded to Abyssinia (AKA Ethiopia) where he found the Christian emperor Eskender, whom he assumed was Prester John. While honorably treated and awarded with estates and wealth, Covilha was prevented by Eskender and his successors from leaving Abyssinia. While there, Covilha maintained correspondence with the home government in Portugal, supplying it with vivid descriptions of the wealth and splendor of Abyssinia. In 1520 a Portuguese embassy arrived, which Covilha helped with his talents as an interpreter. However, he was never allowed to leave Abyssinia, where he died in 1530.

Around the Cape of Storms to India (1497-9)

“...henceforth all Christendom in this part of Europe shall be able...to provide itself with these spices and precious stones.”—Manuel I of Portugal

The Portuguese sent out a fleet of three strong square-rigged ships (*naus*) and one caravel manned by a total of 170 men. It was under the command of Vasco da Gama (above), described as a “man of iron physique,” surly, brutal and violent, but also loyal and fearless, all of these necessary qualities for the commander of such an expedition.

Another time, he took the high priest of Calicut, who had been sent to discuss da Gama’s demands for the expulsion of all Muslims from the city, cut off his ears and lips, sewed dog’s ears onto his head, and sent him back to his master.

The expedition set sail on July 8, 1497. However, Instead of hugging the coast, da Gama sailed straight south into the open ocean and picked up the South Atlantic westerlies that Dias had discovered in 1487. Using these winds, they reached the Cape in three months, having sailed across 6,000 miles of open sea, the longest such voyage in history up to that point.

Having reached the Cape, they broke up one *naus*, distributed the surviving crew and supplies to the other ships, and headed up the African coast to Mozambique.

At Mozambique, da Gama impersonated a Muslim out of fear of hostility to Christians. Although gaining an audience with the sultan, his paltry trade goods proved to be insufficient gifts to impress his host. This aroused the suspicions and hostility of the locals and the Portuguese had to flee, sailing north to Mombasa.

Meanwhile an Arab-speaking pilot of Da Gama's had learned there were ports further north trading spices, pearls, and rubies, and also that Prester John lived in cities along the coast!!

On the way to Mombasa, they looted Arab merchant ships. Not surprisingly, at Mombasa, da Gama encountered hostile Arab traders unwilling to show him the way to India. However, after "questioning" (da Gama's term) two Moorish prisoners by dropping boiling oil on their foreheads to jar their memories, he managed to learn he could find Hindu pilots up the coast at Malindi, whose rulers were at war with Mombasa. There he recruited a Hindu pilot familiar with the monsoons to guide him to India.

Following Pero da Covilha's advice, the Portuguese sailed to the Indian port of Calicut. Unfortunately, after an initially friendly reception, the ruler was unimpressed with the gifts da Gama had brought from Portugal (four scarlet cloaks, six hats, four coral branches, a box containing seven brass vessels, a chest of sugar, two barrels of oil and a cask of honey).

Local Arabs, naturally hostile to the Portuguese, suggested they were pirates instead of ambassadors. Relations soured even more when Calicut's ruler demanded gold as customs payments. In response, da Gama seized several hostages and somehow managed to trade his goods for local ones worth 60 times the cost of the expedition.

The Portuguese thought Hindus were Christians with Krishna as Christ and his mother, Devaki, representing the Virgin Mary. In addition:

"They threw holy water over us and gave us some white earth, which the Christians of this country are in the habit of putting on their foreheads, breasts, around the neck, and on the forearms...Many other saints were painted on the walls of the church, wearing crowns. They were painted variously, with teeth protruding an inch from the mouth, and four or five arms."

Against local advice, da Gama set off for home against the monsoons. Thus, while the trip from Malindia to Calicut took only 23 days, the return trip there took 132, forcing him to abandon another ship due to disease. The remaining journey from Malindi around Africa back to Portugal took another seven months, with only 44 of 170 men having survived the round trip.

Da Gama's epic 28,000 mile voyage, the longest in history up to that point, earned him great wealth and status, including the title of Admiral of the Indian Seas. It also opened the lucrative spice trade to Portuguese exploitation.

Even more importantly, it showed India could be reached by sea from Europe. But it also raised new questions, such as where was the Great Southern Continent and could the earth be circumnavigated by ship.

Spain goes West: Columbus

Ghirlandaio's posthumous portrait of Columbus. There are no known authentic portraits of him.

Christopher Columbus is such an icon in our history that it's easy to lose sight of the real man behind history's mask. He was a visionary as far as the possibility of sailing west to reach Asia was concerned. He was also one of the great sailors of his day, having traveled from Iceland down to the Guinea coast of West Africa. His experience with the Portuguese also gave him valuable knowledge of the trade winds, which he used skillfully on his voyages. He believed it was possible to make the voyage from Europe to Asia with the existing nautical technology.

Although not the first to make it to the Western Hemisphere, he was the one who made that

discovery stick and turn Europe's eyes westward to a "New World"

Columbus was also probably familiar with the incident of two strange looking people with light brown skin and flat faces who had washed ashore in Galway west of Ireland. Most likely they were Inuits whose kayak had been swamped and their bodies swept eastward and preserved by the cold North Atlantic current. To Columbus, this was one more bit of evidence that China lay to the not so distant West. Adding to this was the rumor of a pilot who had barely survived long enough to tell his tale of his caravel being blown far off course from Africa to the West and landing in a strange land from which he had managed to return.

Columbus did have a penchant for believing what he wanted to believe. He had something of a persecution complex, could be greedy, and was not above distorting facts to make his case. Not that educated people of the time didn't believe in a direct sea route to Asia, just that it was too long for the existing ships. Therefore Columbus stretched his age's version of the truth to conform more nicely to his own beliefs and get support for his scheme.

Much of Columbus' miscalculations came from discrepancies between the Arabic mile of 1,830 meters, which geographic texts used, and the Italian mile of 1,238 meters, which he used. Therefore, he estimated the circumference of the earth at the equator at 25,000 kilometers, 15,000 short of the real distance.

Columbus relied on the Florentine astronomer and cosmographer Paolo del Pazzo Toscanelli (1397–1482), a copy of whose map he took on his voyage. He also used some creative wishful thinking to reduce the length of the voyage to 3,700 km. (In fact it is 19,600 km.) Ironically, the distance from Europe to America is about 3,700 kilometers. No wonder Columbus thought that he had found Japan (Zipangu).

Much of Columbus' problems came from timing. Kings in England and France were pulling their realms together after the Hundred Years War, and Portugal was already committed to sailing around Africa. Columbus'

ego and the high price he demanded for his services didn't help either. However, he had supporters who kept his case alive, especially at the Spanish court, which was preoccupied at the time with the conquest of Granada.

Once they had conquered Granada in January 1492, Ferdinand and Isabella of Spain were ready to support Columbus' voyage westward to find Asia. Another factor was Dias' rounding the Cape of Good Hope in 1488. It might be worth risking three ships to find a cheaper and easier way to Asia and beat the Portuguese there. Contrary to legend, Isabella did not pawn her crown jewels to finance Columbus's expedition. She had already pawned them to pay for artillery in the conquest of Granada.

Columbus set sail August 3, 1492 with his three ships, the Nina, Pinta, and Santa Maria. Sailing south to pick up prevailing easterlies provided perfect sailing conditions. In fact, they seemed too perfect to the sailors who worried about how they would get back against those same winds. They were also concerned that they would get entangled in a sea of seaweed and never be able to get out.

To calm their fears, Columbus lied to them about how far they had gone, telling them a shorter distance than he had calculated. Ironically, the figure he gave them was closer to the truth, since he had overestimated how far they had actually gone.

By early October, Columbus' sailors were close to mutiny, so he promised to turn back if they didn't sight land in three days. He also promised a hefty reward to the first sailor who sighted land. (He later cheated that sailor, Rodrigo de Triana, claiming he was the first one to see land.)

On October 12, 1492, much as he predicted, Columbus hit land about 3000 miles west of Europe, christening the island San Salvador, although it's not known for sure on which island he first landed. The natives were friendly, but given their primitive technology, he assumed he must have hit the outlying islands of Cipangu (Japan)

He moved on to the much larger island of Cuba. Assuming this was Japan, he sent a man as ambassador, since he knew Arabic, which might be known in East Asia. Instead of the Japanese emperor, all he found were natives smoking cigars, the first European encounter with tobacco.

On Christmas Day, 1492, the Santa Maria ran aground and had to be abandoned. Columbus, with the permission of the locals, left behind 39 crewmen in a colony they called La Navidad. When Columbus returned on his second voyage, he found the colony burned and the colonists massacred by the natives, probably in reaction to mistreatment by them.

Much controversy surrounds Columbus' character, and in particular his treatment of the natives, many of whom he enslaved, while his men raped the women. There are stories of the Spanish turning their dogs on them, hanging many of them for the slightest thefts, and even taking babies born to sailors and native women and tossing them into the jungle to die. Although one of his missions was supposedly to convert the natives, he refused to do so since the Church prohibited enslaving fellow Christians.

Montezuma's Revenge? While European diseases would kill off millions of Native Americans, the Spanish sailors probably brought back to Europe an American disease, syphilis, most likely contracted from raping some of the Native American women. Syphilis would wreak havoc with Europe's population for generations. It was possibly the reason that Charles VIII's army had to retreat from Italy in 1494, thus earning it the undeserving title of the "French disease."

Supposedly, Syphilis even had an impact on fashion, namely the widespread use of wigs in the 1600s and 1700s to cover up the loss of hair from being infected.

For his return voyage, Columbus refitted his two remaining ships, the caravels Nina and Pinta, with square sails. He then sailed north to catch the prevailing westerlies home. However, sailing the Atlantic during the winter is risky, making this a rough voyage with a storm forcing them into Lisbon harbor for a week before finally returning to Spain.

Columbus was received with great excitement at court, the 7 or 8 "Indians" who had survived the voyage especially making a stir. However, Ferdinand and Isabella were disappointed at the low return in gold (mostly earrings stripped from the natives). Columbus assured them he had reached the outer islands of Asia, and that another voyage would bring the expected treasure.

As a result, for his second voyage, Columbus was given 17 ships with 1200 men, including farmers, and priests, the plan being to settle these new lands and convert the natives to Christianity, although there were serious debates within the Church about if the natives actually had souls and were worth the trouble. After discovering Puerto Rico and exploring Cuba, which he thought was a peninsula attached to Asia, he returned home in 1494, once again with little gold.

In 1498, Columbus was sent with six ships on a third voyage. Unfortunately, incomplete knowledge of the trade winds led to him getting stuck in the doldrums, or Horse Latitudes, where there are no prevailing winds. The expedition was down to its last barrel of water when they finally hit land.

On this voyage, the Spanish explored some of the coast of South America, discovering the Orinoco River, which Columbus believed was the river to Paradise. However, his sailors thought it was the way to Hell and refused to explore it.

Complaints about his tyrannical rule (including hanging several sailors for insubordination) and bitterness by colonists on Hispaniola about being misled by his promises of easy riches, the governor of Hispaniola had Columbus arrested.

Although he was released several weeks after returning to Spain, he was never restored his governorship.

On his fourth and final voyage (1502-4), Columbus' four ships survived a horrific hurricane. They were then stranded on Jamaica for a year, the governor of Hispaniola being unwilling to rescue Columbus, whom he hated. What sustained Columbus during that year was food supplied by the natives whom he impressed by successfully predicting a lunar eclipse. Help finally arrived and Columbus returned to Spain in 1504.

Columbus died in 1506 at the age of 55. Although wealthy from gold he had plundered in Hispaniola, he was bitter at not being awarded any revenues after his dismissal from that position. Being of relatively humble birth from Genoa probably contributed to his unpopularity among the Spanish nobility as an upstart and to his own persecution complex.

To his dying day, he believed he had found Asia instead of a New World.

In two other voyages between 1499 and 1502, another Italian sailing for Spain, Amerigo Vespucci, explored and mapped more of the coast of South America. While Columbus discovered America, Vespucci was probably the first to recognize it as a "fourth continent". In 1507, a German cartographer, Martin Waldseemüller, published a map with the New World labeled "America". The name has stuck ever since.

What remained was the question of where was Asia?

Magellan and the first circumnavigation of the globe (1519-22)

And I believe that nevermore will any man undertake to make such a voyage." --Antonio Pigafetta

Columbus' discoveries led to a flood of Spanish adventurers seeking their fortunes. Among them was Vasco Núñez de Balboa (c.1475 - 1519), who crossed the Americas at their narrowest point and discovered the Pacific "Sea", because, according to the still prevailing theories of a small planet, there wasn't enough room for another ocean like the Atlantic, let alone one two and a half times its size.

Unbeknownst to Balboa, while he was discovering the Pacific "Sea" from its eastern shores, the Portuguese explorer, Francisco Serrão, was doing the same from the opposite side of the planet's largest ocean.

Columbus' first voyage led to a dispute between Spain and Portugal about who could claim what in the East. At the time, it wasn't clear what Columbus had found, so it looked like the East was up for grabs.

Therefore, in 1494 the pope brokered a deal, the Treaty of Tordesillas, which drew a line of Demarcation in the middle of the (Atlantic) Ocean (the only known ocean at the time). Anything west of that line was Spain's to claim. Anything east of it was Portugal's. The question was: where did it come out on the other side? To know that required knowing how large the earth really was (and still is).

In 1500, when Pedro Álvares Cabral set off for India, he followed da Gama's advice and swung southwestward to pick up the westerlies to swing him around Africa. A storm blew his fleet off course and they landed in Brazil, which according to the Line of Demarcation, was on the Portuguese side.

In 1519, outside of what had been explored so far, what a map of the rest of the world looked like and its real size was anyone's guess. Along came Ferdinand Magellan, a Portuguese adventurer who had served Portugal in the Far East, knew the area, and after a falling out with his king, offered his services and knowledge to Spain.

Given a small planet with only a Pacific “Sea”, Magellan thought America was just a peninsula (Malay Peninsula?) protruding from Asia. Therefore, one could easily find a southwest passage around it and reach the Spice Islands after a much shorter voyage than going around Africa.

The Spanish king Charles I (Holy Roman emperor Charles V) gave Magellan five ships and 240 men to test his theory. Unfortunately, corrupt contractors shortchanged the expedition, leaving it poorly supplied.

The main trade item Magellan took was 20,000 hawk bells to hang around the necks of hunting hawks. For some reason, they thought people in Asia would want that.

They didn't.

The expedition left in 1519. It had an easy crossing to America, but had to avoid the Brazilian coast since that was Portuguese territory. However, a storm off Patagonia left the expedition only 4 ships.

Among his other troubles, Magellan had to face a mutiny, since his sailors were scared of what might lay ahead and, being Spanish, they didn't trust their Portuguese commander. At times like this ships needed strong, decisive, and even ruthless captains who were entrusted with the power of “the rope and knife” (i.e., life and death). Magellan was such a man. During a parley, his first mate cut the throat of the mutiny's ring-leader, Mendoza, while sailors loyal to Magellan stormed aboard to quell the mutiny.

The stormy passage through the Straits of Magellan took Magellan 38 days, while today it takes only two. During this passage, another ship, the *San Antonio* mutinied and fled back to Spain, spreading slander to Charles V about Magellan.

Then, without adequately resupplying, Magellan's three ships set out on the short voyage across the Pacific “Sea”.

Antonio Pigafetta accompanied Magellan on his voyage and wrote an account of the journey. Following is his account of the Pacific crossing:

"On Wednesday the twenty-eighth of November, one thousand five hundred and twenty, we issued forth from the said strait and entered the Pacific Sea, where we remained three months and twenty days without taking on board provisions or any other refreshments, and we ate only old biscuit turned to powder, all full of worms and stinking of the urine which the rats had made on it, having eaten the good. And we drank water impure and yellow. We ate also ox hides, which were very hard because of the sun, rain, and wind. And we left them...days in the sea, then laid them for a short time on embers, and so we ate them. And of the rats, which were sold for half an ecu apiece, some of us could not get enough.

"During these three months and twenty days, we sailed in a gulf where we made a good 4000 leagues across the Pacific Sea, which was rightly so named. For during this time we had no storm, and we saw no land except two small uninhabited islands, where we found only birds and trees. Wherefore we called them the Isles of Misfortune. And if our Lord and the Virgin Mother had not aided us by giving good weather to refresh ourselves with provisions and other things we would have died in this very great sea. And I believe that nevermore will any man undertake to make such a voyage."

Following is Pigafetta's account of the effects of scurvy during the Pacific crossing:

"It rotted all my gums which gave out a black and putrid blood. My thighs and lower legs were black and gangrenous, and I was forced to use my knife each day to cut into the flesh in order to release this black and foul blood. I also used my knife on my gums, which were livid and growing over my teeth...When I had cut away this dead flesh and caused much black blood to flow, I rinsed my mouth and teeth with my urine, rubbing them very hard...Many of our people died of it everyday, and we saw bodies thrown into the sea constantly, 3 or 4 at a time. For the most part they died with no aid given them, expiring behind some case or chest, their eyes and the soles of their feet gnawed away by rats.

"Besides the aforesaid troubles, this malady (scurvy) was the worst, namely that the gums of most part of our men swelled above and below so that they could not eat. And in this way they died, inasmuch as twenty-nine of us died...But besides those who died, twenty-five or thirty fell sick of divers maladies, whether of the arms or of the legs and other parts of the body (also effects of scurvy), so that there remained very few healthy men. Yet by the grace of our Lord I had no illness."

Slowly the tiny flotilla made its way across the unknown vastness of the Pacific. At last they reached Guam, which Magellan called the Island of Thieves because the natives stole much of his cargo. However, they did manage to replenish their supplies and push on.

In March 1521 they reached the Philippines with 150 men. They were able to communicate with the natives because Enrique, a Malay servant indentured in 1511 by Magellan during his service to Portugal in the East, knew the local language and served as interpreter. Unfortunately, when Magellan helped a tribal leader, who had conveniently converted to Christianity, against another tribe, he and his 50 men were overwhelmed by 1500 natives and he was killed.

Soon Afterwards, a third ship, the *Concepcion*, had to be abandoned because so many crew had

died, many of them in the battle in the Philippines.

Even counting his previous Portuguese service in the East, Magellan probably fell just short of being the first man to circumnavigate the globe. That honor, ironically, went to his Malay servant, Enrique who, several days after Magellan's death, got his freedom with the help of a local native leader, despite the efforts of the Spanish to keep him and his linguistic skills. Luckily, Pigafetta had written down about 145 words from the local languages and served as the expedition's interpreter from that point on.

After Magellan's death, command of the expedition fell to Sebastian del Cano. With the help of local pilots, the Spanish navigated the shallow seas to Brunei, where they loaded their ships with cloves, a product the locals disdained but Europeans valued as much as gold.

With 115 men left, the two remaining ships, *Trinidad* and *Victoria*, continued westward. But the *Trinidad* started taking on water and, there being no room on the *Victoria*, had to be left with its crew. After making repairs, the *Trinidad's* crew attempted to return across the Pacific, but gave up and were captured by the Portuguese.

In order to avoid capture by the Portuguese, whose waters they were now in, the Spanish sailed across the open sea around the Cape of Good Hope and up the west coast of Africa. Cold, disease, and starvation claimed 20 more lives before they put in at the Cape Verde Islands for supplies. While Spanish ships in those waters were not unusual, Spanish sailors paying for their supplies with cloves were. The Spanish had to run for it, leaving 13 comrades in order to save their 26 tons of cloves and cinnamon.

On September 22, 1522, almost exactly three years after setting out, the *Victoria* landed in Spain with its 18 surviving members. The first thing they did was go (some of them so weak they had to crawl) to the local church to thank the Virgin Mary for their survival.

Of the 55 crewmen of the Trinidad, four would survive and make it home.

Another 232 crewmen never made it home.

Curiously, the sailors' calendar was one day behind the home calendar, because they had followed the sun for one revolution around the globe and seen one less sunrise than the people back home.

Pigafetta was right in that no one would want to repeat Magellan's feat for nearly a century. The next man to do it would be Sir Francis Drake, who did it to avoid capture by the Spanish navy after he had plundered one of their treasure ships. It would also take him three years to complete the voyage (1577-80).

When Worlds Collide: Cortez & the Aztecs

The myth of Quetzalcoatl concerned a feathered serpent god and his priest, both called Quezalcoatl. The priest, who had fair skin and a heavy beard, had been driven into exile over the ocean but vowed to return, according to some versions in the year 1519, the very year Cortez arrived. Therefore, the Aztec ruler, Montezuma II, was increasingly bothered by strange omens that seemed to portend Quetzalcoatl's return: uncontrollable fires in the temples, strange lights in the sky, and reports of armed warriors riding monsters like deer, but bigger.

Ready to take advantage of these portents was a Spanish adventurer, Hernan Cortez.

Cortez was a Spanish soldier and adventurer who had fought in the Italian wars and then came to Cuba to seek his fortune. When he heard reports of a fabulous and wealthy civilization in Mexico, he talked the governor of

Cuba into letting him organize an exploratory expedition.

However, Cortez' intentions all along were to go beyond his governor's orders and conquer and plunder the Aztecs. Therefore, upon landing in Mexico, he burned his ships (below) so there was no turning back for the rest of his men.

He had 553 men and 16 horses with which he planned to conquer an empire of millions.

When an Aztec embassy greeted Cortez with gifts, hoping that he would be satisfied with them and leave, this only whetted his appetite for more.

As the Spanish marched toward Tenochtitlan, they were attacked by subjects of the Aztecs known as the Tlaxcalans. The Spanish defeated the 30,000 Tlaxcalan warriors and convinced them to join them in rebellion against their hated masters. Support from the Aztecs' disgruntled subjects would be a major factor in Spanish success.

In battle, steel armor & weapons, along with gunpowder and these strange new beasts, horses, gave the Spanish conquistadors a huge advantage over the wooden and obsidian war clubs that the Aztecs used. For a while, the Aztecs thought the horses and their riders were one creature.

In one battle in Peru, Francisco Pizarro's army killed or wounded 2000 of the enemy, while only losing five men.

Also nullifying their superiority in numbers were the Aztecs' concern with taking prisoners for sacrifices to their gods and their failure to bring all their warriors into the battle at once.

However, the Aztecs were anything but pushovers in battle:

"We noted their tenacity in fighting, but I declare that I do not know how to describe it, for neither cannon nor muskets nor crossbows availed, nor hand to hand fighting, nor killing 30 or 40 of them every time we charged, for they still fought

*with more energy than in the beginning.”—
Bernal Diaz*

Diaz also described the Spaniards' first impression of Tenochtitlan:

“We were amazed on account of the great towers & buildings rising from the water and all built of masonry. And some of our soldiers even asked whether the things we saw were not a dream...Gazing on such wonderful sights, we did not know what to say, or whether what appeared before us was real, for on one side, on the land, there were great cities, and in the lake were so many more, and the lake itself was crowded with canoes...And in front of us stood the great city of Mexico, and we--we did not even number 400 soldiers.”-

Montezuma II met Cortez outside Tenochtitlan, hoping to persuade him to leave. However, Cortez, accompanied by his interpreter, Dona Marina, (whom he later married), could see Montezuma's nervousness and insisted on entering the city.

Still worried that Cortez might be Quetzalcoatl, the Aztecs put him up in their best palace. Feeling uneasy about how calm the city seemed, Cortez seized Montezuma as a hostage to ensure the Aztecs' good behavior.

Meanwhile, word came that the governor of Cuba had sent another force to relieve Cortez. Cortez went with part of his force and succeeded in winning this relief force over to his side.

However, during a ritual dance put on in their honor, the Spanish left behind in Tenochtitlan attacked their Aztec hosts and then toppled the pagan idols from the Aztec temple.

The Aztecs, no longer convinced the Spanish were gods, attacked them and put them under siege in their palace.

When Cortez returned, he tried to use Montezuma to calm his subjects, but they killed him as he spoke, thus removing the last bit of leverage Cortez had over the Aztecs.

The Spanish, in desperate straits, decided they must try to escape Tenochtitlan at night, building a portable bridge to cover the three gaps left in the causeway by the Aztecs to block their exit. At first, they seemed to go undetected, but then the huge drum atop the city's main pyramid sounded the alarm and suddenly thousands of warriors were swarming about them in canoes, their war cries piercing the night.

A furious running battle ensued as the Spanish spanned the first gap with their portable bridge. But it got stuck, and as they approached the second gap, the crush of those behind pushed those in front into the water. Being weighed down with armor and gold, they drowned, eventually filling the gap with a bridge of bodies, loot, and weapons over which the others could cross.

They passed the third gap in the same bloody way. All this while the giant drum kept booming and wave after wave of Aztec warriors in war canoes assaulted them from all sides.

Somehow, Cortez and a few of his men managed to fight their way out of the city and gathered around a cypress tree that still stands in Mexico City. Ever since in Mexican history, this has been known as “Noche Triste” (the sad night).

Undaunted Cortez fought his way back to his Tlaxcalan allies and gathered a new army.

This time he had a new ally: smallpox.

Having no prior exposure to European diseases, native Americans had virtually no resistance. As a result they would die by the thousands, and eventually by the millions.

Along with the tremendous loss of life, these diseases caused tremendous psychological damage among Native Americans, whose world suddenly was coming apart for no apparent reason.

The next year (1520) Cortez returned with a new army of 600 men and 40 horses along with 100,000 allied warriors, and 13 pre-fabricated ships armed with cannons so he could assault the now disease-infested Tenochtitlan by both land and sea.

Even after breaking into the city, the Spanish faced fierce resistance in house to house fighting all the way to the central plaza where the Aztecs made a desperate last stand.

In the end, Tenochtitlan and the Aztec Empire fell, but Cortez' Mexican allies soon found they had exchanged a bad master for a much deadlier one.

When Worlds Collide II: Pizarro and the Incas

Francisco Pizarro (above), the conqueror of the Incas, was a distant relative of Cortez and also a soldier with fighting experience in the Italian wars. In 1502 he came to the New World and made a fortune in Panama from farms worked by Indian slaves and partial ownership in a gold mine. However, he wanted much more.

In 1526, after one abortive attempt at exploring the Pacific coast of South America, Pizarro led a second expedition that caught and plundered a balsa trading raft from Peru that was full of valuable goods, including gold, silver, and emeralds. Despite the refusal by the Spanish governor of Panama to send reinforcements, Pizarro continued south with a handful of comrades and entered a rich and heavily populated area of the Inca Empire. The friendliness of the natives and the wealth he found there made him even more determined to conquer Peru.

Since the governor of Peru would not sanction another expedition, Pizarro went over his head

to Charles I of Spain (the Holy Roman Emperor Charles V) to convince him of the wealth he could bring to Spain by conquering the Incas. Pizarro received the Capitulation of Toledo (1528), which authorized him to raise an army of 250 men to conquer Peru and made him its governor general.

In 1532 Pizarro entered Peru with about 180 men and 27 horses. He had several factors helping him in his quest to conquer this empire of millions with only 168 men (106 infantry and 66 cavalry). For one thing, the Spanish had superior weapons and a more effective method of fighting battles. These, plus horses, which the Incas had never seen, gave Pizarro a psychological edge. Also, the emperor Atahualpa had just finished a civil war with his brother, Huascar, so the Incas were somewhat worn out by that. Finally, and ultimately most important, smallpox had preceded the Spanish and was already wreaking physical and psychological damage among the population.

After months of long-range negotiations with Atahualpa carried on by Hernando de Soto, Pizarro advanced into the heart of the Inca Empire, setting up camp in the city of Cajamarca as Atahualpa approached with an army of 80,000 men. Pizarro knew he could neither defeat such a huge army, nor retreat, since it would show weakness in the midst of the enemy. Therefore, he decided to seize Atahualpa, hoping to paralyze the Incas with fear and indecision without their absolute leader to tell them what to do.

For some reason, Atahualpa agreed to a parley inside Cajamarca, accompanied only by an unarmed retinue. At first a priest tried to convert the emperor, who asked to see a Bible that the priest said talked to him. Having never seen a book or writing, the priest reached over to help him open the book. Atahualpa struck the priest's arm, opened the book, and when it didn't talk to him, threw it to the ground.

According to one version, the priest turned and urged the Spanish, who were hidden around the plaza, to rush and capture the Inca ruler.

Caught by surprise, plus never having seen guns or horses, the Incas were easily overwhelmed by a cavalry charge coordinated with gunfire (including four small cannons). The resulting Battle of Cajamarca was more a massacre than battle, the Spanish killing 2,000 Incas while only losing five men. The remaining Incas fled and Pizarro captured their emperor. With their emperor captured and other leaders killed, the Incas were paralyzed into inaction.

After his capture by Pizarro, the captive emperor, Atahualpa, promised to give Pizarro a room filled with gold and two other rooms with silver in return for his release. However, having received the ransom, Pizarro had Atahualpa strangled and then made his younger brother, Túpac Hualpa, puppet emperor of the Incas.

Soon afterward Túpac Hualpa died of smallpox, so Pizarro appointed Manco Inca Yupanqui as emperor, hoping to rule through him. However, mistreatment by Pizarro's brothers prompted Manco Inca to escape and stir up a rebellion, supposedly raising an army of 200,000 men. After being defeated by the Spanish, Manco retreated into the mountains where he held out until his death in 1544. His son, Túpac Amaru, succeeded him as the last ruler of the Inca, finally being murdered by the Spanish in 1572.

Meanwhile, the Spanish had stormed the Inca capital, Cuzco, destroyed every building in it, and built a Spanish city on top of it. They then proceeded to plunder the former Inca Empire.

The silver mines around Potosi would be the mainstay of the Spanish monarchy for a century. Unfortunately, most of that wealth would largely be wasted on a series of religious wars that would leave Spain, the superpower of the 1500s, exhausted by 1650.

So how could an army of 180 men bring down an empire of millions? Paralyzing their command structure by capturing it helped. But the real culprit may have been smallpox, which preceded Pizarro into Peru and had killed thousands by his arrival in 1532. Among its

victims may have been Atahualpa's predecessor.

As devastating as the physical effects of a new and strange epidemic on a population might be, the psychological effects could be much worse. Pizarro told the Incas that smallpox was God's punishment on them, and, having no other explanation, they may have believed it. As their whole concept of order and the universe crumbled away, they became easy prey for the agents who said they had brought this plague.

Estimates vary. But by 1600, as much as 90% or more of the native population in the Americas would be wiped out, partly by mistreatment, but mostly by European diseases.

THE PORTUGUESE EMPIRE IN THE EAST (1500-c.1600)

Even before da Gama had set out for India, Christopher Columbus, had returned from what he believed was a direct route to Asia. This provoked a dispute between Spain and Portugal over who could claim what territories outside of Europe. In 1494, the pope arbitrated the dispute and drew a Line of Demarcation down the middle of the Atlantic. Everything outside of Christian Europe and west of the line belonged to Spain; everything east of it was Portugal's to claim. The line extended all around the globe, but since the size of the earth was not known, just where that line came out was anybody's guess. Despite these uncertainties, the Pope's Line of Demarcation determined the direction of both Spanish and Portuguese explorations. For the Portuguese, this meant they must control the trade routes to the East.

In 1500, only a year after da Gama's return, Pero Alvares Cabral followed da Gama's route to India with a fleet of ten Portuguese ships. Using da Gama's tactic of swinging westward to pick up westerly winds to take him around the Cape of Good Hope, he accidentally hit Brazil which juts eastward into the Atlantic. Since that part of Brazil lay east of the Line of Demarcation, Cabral claimed it for Portugal. He continued to India, but found the same problems da Gama had encountered: Arab hostility and an unwillingness to trade for European goods.

Therefore, the Portuguese decided to change their approach. The third expedition to India, led by da Gama in 1502, took 14 well-armed ships that would take the spice trade by force. The bulky European ships, built to stand the rough Atlantic seas, also provided excellent gun platforms for artillery, and that was the decisive factor in the battle that followed as the Portuguese beat the Arab fleet opposing them. A second decisive victory by the Portuguese fleet in 1509 established the Portuguese reputation for naval invincibility in Eastern waters and started Portugal on the road to establishing a maritime empire in the East.

The architect of the Portuguese Empire in the East was a capable and daring leader, Alphonse de

Albuquerque. He realized that such a tiny state as Portugal could not conquer a land empire in Asia and run it all the way from Europe. Therefore, he concentrated on seizing key strategically placed ports that could control the flow of the spice trade. First he captured the strongly fortified island of Goa off the coast of India. From there he could strike out in several directions. Although he failed to cut off Muslim trade coming out of the Red Sea, he did cut off much of the Arab trade by seizing Ormuz at the tip of the Persian Gulf through some masterful bluffing and sailing with only six ships.

The Portuguese maintained their dominance of the East through a combination of astute and ruthless policies. Albuquerque was especially talented in establishing the proper ratio of escort ships to cargo ships. The Portuguese also blackmailed other merchants into paying for certificates of free passage in the Far East. For a few years they managed to have nearly all spices headed for Europe traveling on Portuguese ships.

However, there were serious limits to Portugal's power in the East, which led to the eventual decline of its Empire in Asia. For one thing, the Portuguese, in a fit of religious fervor, had expelled their Jewish bankers and merchants from Portugal, thus eliminating most of Portugal's business community. As a result, the Flemish port of Antwerp handled most of Portugal's spice trade and took much of its profit. Second, Portugal's empire put a tremendous strain on its very limited manpower. Along these same lines, it was very expensive to maintain forts, garrisons, and fleets, especially over such long distances. Finally, the hostility of local rulers, in particular the Mughal Dynasty ruling India, put extra strains on Portugal's ability to hold its empire.

All these factors cut deeply into Portugal's profits and prompted several cost cutting moves. The Portuguese cut corners by not maintaining their ships in the best condition. They would replace lost European crewmen with half-trained natives unfamiliar with European ships and rigging. Finally, because of the limited number of ships and the desire for as large a profit as possible, they would over pack their ships with spices. All these measures led to costly shipwrecks, which cut further into Portuguese profits and caused even more of these cost cutting measures. By 1600, the

Portuguese Empire in Asia was in serious decline and increasingly losing ground, first to the Dutch and later to the English.

A complicated three-way trade.

The lengths to which Europeans would go to get Eastern luxuries is possibly best seen in the three-way trade carried on by Spain and Portugal to get Chinese goods, in particular porcelains. (Even today we refer to our good dishes as “China”.)

In 1513, the Portuguese reached China and tried to open trade with the Middle Kingdom. However, the Chinese weren’t interested in the stuff the Europeans offered, the only thing they were interested in being silver, which was relatively scarce in China.

The Portuguese didn’t have silver, but the Spanish did, the Potosi silver mines of Peru being the most productive in the world. Thanks to Magellan, the Spanish also had the Philippines, which was a convenient meeting place for the two peoples. Finally, the Portuguese had something the Spanish wanted: spices. Out of this emerged what was probably the first global exchange. Step by step, it went like this

1. The Portuguese sailed to the Spice Islands and traded European goods for spices. Meanwhile, the Spanish took their silver from Peru to Panama.
2. The Portuguese sailed to the Philippines with part of their spices. Meanwhile the Spanish sailed all the way across the Pacific to the Philippines with part of their silver,

the rest being portaged across Panama and then taken by ship to Europe.

3. The Spanish traded their silver for Portugal’s spices in the Philippines.
4. The Portuguese sailed to China & traded their Spanish-American silver for Chinese goods. The Spanish took their spices back across the Pacific in grueling 4-7 month voyage
5. The Portuguese sailed all the way home around Asia and Africa to sell their Chinese goods and spices. Meanwhile, the Spanish portaged their Chinese goods across Panama and sailed home to sell them in Europe.
6. Start all over again at 1.

Maintenance of Ships and Sailors

A ship dry-docked in Boston harbor for refitting.

Wooden sailing ships required a lot of work to keep them serviceable for any length of time. In addition to replacing sails and rigging, the hulls had to undergo extensive repairs every few years.

The first thing to do was dry-dock the ship. Rather than hauling it up onto shore, they let the tides do the work. The ship was put inside a shallow pen at high tide. When the tide went out, it left the ship high and dry inside the pen, which was then shut and sealed off from the next tide. With the ship lying on one side of its hull, they would rip out and replace any rotten timbers, seal the hull with a fresh coat of tar or pitch, and cover it with a layer of copper or lead sheathing to protect it against sea worms. When that side was finished, the tide was let in to float the ship upright, and then let out again to lay

the ship on its other side, which they would also repair. Then the tide would be let in one more time to set what seemed like a brand new ship afloat and back out to sea.

Such scheduled maintenance could extend a ship's life by a factor of several times. For example, Lord Nelson's flagship, Victoria, would have lasted four or five years without maintenance. With regular maintenance, it stayed in service for a quarter of a century. It was also a lot cheaper than building a whole new ship every few years.

A good night's sleep for sailors. From a sailor's point of view, the discovery of Brazil provided them with one of the most useful inventions of the Age of Exploration: the hammock. Previously, they had to find whatever space was available on a crowded ship for sleeping. Not only that, they had to share that space with the rats and whatever other creatures happened to be on board. The hammock suspended them comfortably above all that. Besides the health benefits, it may have avoided a number of mutinies fomented by cranky sailors who just needed a good night's sleep.

Crewmen asleep in their hammocks aboard a sailing ship

THE WORLD MAP TAKES SHAPE: LATER VOYAGES OF EXPLORATION (c.1550-1900)

The progress of the past 150 years still left many questions to answer and myths to dispel concerning the world map. Subsequent explorations concerned four main issues and followed four lines of development:

- 1) Finding a practical northwest passage around North America to Asia;
- 2) Finding a practical northeast passage around Scandinavia to Asia;
- 3) Determining if North America and Asia were connected or separate, which would determine if any north-west or north-east passages, if they existed, could get through to Asia; and
- 4) Looking for a great southern continent to counterbalance the weight of the Northern Hemisphere.

The English largely led the search for a northwest passage. Much of what probably inspired this was the fact that Balboa had walked just a short distance from the Atlantic coast to the Pacific coast at what happened to be the narrowest part in all the Americas. Given that feat, no wonder people expected to find a water passage or narrow isthmus somewhere else in the vast distance the Americas covered from north to south. In 1576, Martin Frobisher, while exploring arctic regions, found an inlet, making him believe he had found the way to Asia and that the Eskimos were Mongols. Further explorations followed. Hopes especially soared in the early 1600's when Henry Hudson found a deep inlet, known ever since as Hudson's Bay. Because of this bay's size and the fact that no one had any idea of North America's size, people believed they had found the way to Asia. However, the Northwest Passage was never found, unless one counts voyages by modern nuclear submarines under the Arctic Ocean's icecap. Of course, the melting of the icecaps from global warming will soon open a Northwest Passage.

At the same time, Europeans were trying to find a northeast passage north of Scandinavia to Asia. The English explorer, Richard Chancellor, reached the Russian port of Archangel, but got no further. He did claim to have "discovered" Russia and established relations between it and England. However, it would not be until the early 1700's that

the czar Peter I would make Russia an integral part of European affairs. Subsequent attempts by Dutch explorers met with similar failures in finding the Northeast Passage. Finally, in 1878, the Swedish explorer, A.E. Nordenskjöld, found the Northeast Passage along the rim of the Arctic Ocean and then down the Bering Straits to Asia. Even today, Russian icebreakers ply the route to keep it open for trade and shipping.

The usefulness of the Northeast Passage depended on whether North America and Asia are connected. If they were, any northwest or northeast passages would be cut off from entering the Pacific. The answer to this hinged on determining the size of North America, which most people then vastly underestimated. Therefore, a number of expeditions explored the northwest coast of North America to find a passage between it and Asia. The key expedition was led by a Russian, Vitus Bering, who found the passage (the Bering Strait) in 1725. He also claimed Alaska, which Russia held until its sale to the United States in 1867.

For whatever reasons, many people did not believe Bering had found this passage; so more expeditions were launched to this region. Spain and England both explored North America's northwest coast both to find the strait of water separating Asia from the New World and claim lands for the growing fur trade. Conflicting claims between the two countries were resolved in 1790, with Britain getting everything from Oregon to Alaska. In the meantime, England's most famous explorer, Captain James Cook, confirmed Bering's discovery. By 1800, the coastal map of North America was pretty much in place.

Expeditions in the South Pacific centered on finding the great southern continent. The Dutch led the way in the 1600's, discovering Australia (literally "Southland"), New Zealand (named after a province of the Netherlands), and Tasmania (named after the Dutch captain, Abel Tasman). Since the Dutch had not circumnavigated Australia, many believed it was the great southern continent. In 1768, the English Captain Cook disproved this by circumnavigating it and New Zealand. On his next voyage, he sailed further south to find out if there was a great southern continent, but rough icy waters forced him to turn back. (On his third voyage, which confirmed the existence of the Bering Strait,

Cook met his death in Hawaii when trying to recover hostages taken by the natives.) It was not until 1820 that the explorer, Nathaniel Palmer, finally discovered the long sought great southern continent, which we call Antarctica.

Conclusion. By 1800, most continental coastlines had been mapped. The following century was mainly one of exploring and settling continental interiors. Two things helped this process, both of them products of the ongoing Industrial Revolution. First of all, the railroad made possible the movement and supplying of large numbers of settlers in continental interiors. This was especially decisive in the development of the interior of North America. Second, germ theory and the development of vaccines for various tropical diseases meant that Europeans could now explore and conquer tropical regions. This particularly affected Africa, known until then to Europeans as the "Dark Continent" since its interior had been so impenetrable.

James Cook: a Captain Worthy of Star Trek
Captain James Cook (1728-79) was the foremost explorer of the 18th century, making three epic voyages to the Pacific, two of them around the world. Among his accomplishments were confirming the existence of the Bering Strait and showing that Australia was an island and not part of a Great Southern Continent. Although generally liked and respected by native peoples he met and treated with respect, he met his end at the hands of Hawaiians in a scuffle very likely over some stolen property he reclaimed.

By most accounts, Cook was a fair and humane captain, excellent navigator, and skilled (and self-taught) cartographer. He was also a good psychologist and adaptable to adverse situations, as the following stories indicate.

Curing scurvy. Cook is credited with the first long-distance voyage that tested the theory that vitamin C could prevent scurvy. However, since there was no way to preserve citrus fruits, the only thing they could use for much of the voyage was pickled cabbage (AKA sauerkraut). Unfortunately, Cook's sailors refused to eat sauerkraut, so he had to trick them much like

parents do to little children. He posted a notice that the officers were to receive double helpings of sauerkraut and the sailors none. The sailors reacted by demanding they be given their shares of sauerkraut too.

Only one sailor died on that voyage, which circled the entire globe. And he didn't die from scurvy.

How to plug a hole in your ship when stuck in the middle of nowhere. While exploring Australia, Cook's ship ran aground on the Great Barrier Reef, which punched a hole in the hull through which the ship was started taking on water. To fix this problem, they first sent a diver to run a rope under the ship and over the hole. Having created a loop, they attached a sail to the rope, threw it overboard, and pulled it under the ship. When the sail was over the hole, the pressure of the water rushing in sucked it into the ship, thus plugging the hole, allowing them to bail out and make the necessary repairs.

A map of Cook's voyages

THE START OF THE PROTESTANT REFORMATION (1517-1546)

Introduction. In the year 1506, a young man by the name of Martin Luther was caught in a violent thunderstorm and nearly hit by lightning. Terrified by this near miss, he vowed he would pursue a career in the Church if he survived. As if in answer to his prayer, nature's storm subsided, freeing Luther to eventually start a more decisive storm in human affairs: The Reformation.

The roots of the Reformation lie far back in the High Middle Ages with the rise of towns and a money economy. This led to four lines of development that all converged in the Reformation. First of all, a money economy led to the rise of kings who clashed with the popes over control of Church taxes. One of these clashes, between pope Boniface VIII and Philip IV of France, triggered the Babylonian Captivity and the Great Schism. Second, the replacement of a land based with a money economy led to growing numbers of abuses by the Church in its desperation for cash. Both of these factors seriously damaged the Church's reputation and helped lead to the Lollard and Hussite heresies based on John Wycliffe's English translation of the Bible and assertion that it was the sole source of religious truth. Therefore, any church practices not found in the Bible should be abolished. These ideas would heavily influence Luther's Protestant Reformation a century and a half later.

Another effect of the rise of towns was a more plentiful supply of money with which to patronize Renaissance culture. When the Renaissance reached Northern Europe, the idea of studying the Bible in the original Greek and Hebrew fused with the North's greater emphasis on religion, thus paving the way for a Biblical scholar such as Martin Luther to challenge the Church.

Finally, towns and trade spread new ideas and technology. Several of these bits of technology, some from as far away as China, helped lead to the invention of the printing press, which helped the Reformation in two ways. First of all, it made books cheaper, giving Luther more access to the Bible and the chance to find what he saw as flaws in the Church's thinking. Second, the printing press would spread Luther's ideas much more

quickly and further afield than the Lollards and Hussites ever could have without the printing press.

All of these factors, growing dissatisfaction with corruption and scandal in the Church, the religious emphasis of the Northern Renaissance, and the printing press, combined to create a growing interest in Biblical scholarship. Nowhere was this interest more volatile or dangerous than in Germany. The main reason for this was the fragmentation of Germany into over 300 states, which helped the Reformation in two ways.

For one thing, there was no one power to stop the large number of Church abuses afflicting Germany, thus breeding a great deal of anger in Germany against the Church. Secondly, the lack of central control also made it very difficult to stop the spread of any new ideas. This was especially true in Germany, with over 30 printing presses, few, if any, under tight centralized control, and each capable of quickly churning out literally thousands of copies of Protestant books and pamphlets. If Germany was a tinderbox, Martin Luther was the spark that set it on fire.

Luther, like all great men who shape history, was also a product of his own age. He had a strict religious upbringing, especially from his father who frequently beat his son for the slightest mistakes. School was little better. Young Martin was supposedly beaten fifteen times in one day for misdeclining a noun. All this gave him a tremendous sense of guilt and sinfulness along with a view of God as a harsh and terrifying being. Therefore, his reaction to the above mentioned thunderstorm in 1506 should come as no surprise. He carried out his vow and became a monk.

As a monk, Luther carried his religious sense of guilt to self-destructive extremes, nearly torturing himself to death through relentless praying, reading, and vigils. Indeed, one morning, his fellow monks came into his cell to find him lying senseless on the ground. Given this situation, something had to give: either Luther's body or his concept of Christianity. His body survived.

Then one night, while reading the Bible, Luther found two passages that would change his life and history: "*For by grace are you saved through*

faith; and that not of yourselves: it is the gift of God; not of works, lest any man should boast.” (Ephesians 2:8-9) *“Therefore, we conclude that a man is justified by faith without the deeds of the law.”* (Romans 3:28) As Luther put it, *“Thereupon I felt as if I had been born again and had entered paradise through wide open gates. Immediately the whole of Scripture took on a new meaning for me. I raced through the Scriptures, so far as my memory went, and found analogies in other expressions.”* From this Luther concluded that faith is a “free gift of God” and that no amount of praying, good deeds or self-abuse could affect one’s salvation. Only faith could do that.

The storm breaks. In the following years, Luther’s ideas quietly matured as he pursued a career as a professor, back then a Church position. Then, in 1517, trouble erupted. Pope Leo X, desperate for money to complete the magnificent St. Peter’s cathedral in Rome, authorized the sale of indulgences. These were documents issued by the Church that supposedly relieved their owners of time in purgatory, a place where Catholics believe they must purge themselves of their sins before going to heaven. Originally, indulgences had been granted to crusaders for their efforts for the faith. In time they were sold to any of the faithful who wanted them. The idea was that the money paid was the result of one’s hard work and was sanctified by being donated to the Church. However, it was easily subject to abuse as a convenient way to raise money.

Indulgence sales were especially profitable in Germany where there was no strong central government to stop the Church from taking money out of the country. This greatly angered many Germans and made them more ready to listen to criticism of the Church when it came. The Church’s agent for selling indulgences in Brandenburg in Northern Germany, John Tetzel, used some highly questionable methods. He reportedly told local peasants that his indulgences would relieve them of the guilt for sins they wished to commit in the future and that, after buying them, the surrounding hills would turn to silver. He even had a little jingle, much like a commercial:

*“As soon as coin in coffer rings
a soul from Purgatory springs.”*

Luther was then a professor in nearby Wittenburg, Saxony, not far from the home of the Hussite heresy in Bohemia. When some local people showed him the indulgences they had bought, he told them they were invalid and a waste of their money. Tetzel denounced Luther for this, and Luther took up the challenge. On October 31, 1517, he nailed a placard to the church door in Wittenburg. On it were the Ninety-five Theses, or statements criticizing various Church practices, some of which are given here.

26. ***“They preach mad, who say that the soul flies out of purgatory as soon as the money thrown into the chest rattles.”***
27. ***“It is certain that, when the money rattles in the chest, avarice and gain may be increased, but the suffrage of the Church depends on the will of God alone...”***
32. ***“Those who believe that, through letters of pardon, they are made sure of their own salvation, will be eternally damned along with their teachers.”***
43. ***“Christians should be taught that he who gives to a poor man, or lends to a needy man, does better than if he bought pardons...”***
56. ***“The treasures of the Church, whence the Pope grants indulgences, are neither sufficiently named nor known among the people of Christ.”***
- 65 & 66. ***“Hence the treasures of the Gospel are nets, wherewith they now fish for the men of riches...The treasures of indulgences are nets, wherewith they now fish for the riches of men.”***
86. ***“Again; why does not the Pope, whose riches are at this day more ample than those of the wealthiest of the wealthy, build the one Basilica of St. Peter when his own money, rather than with that of poor believers...?”***

Luther’s original purpose was not to break from the Church, just to stimulate public debate, a time honored academic tradition. The result, however, was a full-scale religious reformation that would destroy Europe’s religious unity forever.

Soon copies of his Ninety-five Theses were printed and spread all over Germany where they found a receptive audience. Indulgence sales plummeted and the authorities in Rome were soon concerned about this obscure professor from Wittenburg. Papal legates were sent to talk sense into Luther.

At first, he was open to reconciliation with the Church, but, more and more, he found himself defying the Church. Luther's own rhetoric against the Church was becoming much more radical:

“If Rome thus believes and teaches with the knowledge of popes and cardinals (which I hope is not the case), then in these writings I freely declare that the true Antichrist is sitting in the temple of God and is reigning in Rome—that empurpled Babylon—and that the Roman Church is the Synagogue of Satan...If we strike thieves with the gallows, robbers with the sword, heretics with fire, why do we not much more attack in arms these masters of perdition, these cardinals, these popes, and all this sink of the Roman Sodom which has without end corrupted the Church of God, and wash our hands in their blood?”

“...Oh that God from heaven would soon destroy thy throne and sink it in the abyss of Hell...Oh Christ my Lord, look down, let the day of thy judgment break, and destroy the devil's nest at Rome.”

Luther also realized how to exploit the issue of the Italian church draining money from Germany:

“Some have estimated that every year more than 300,000 gulden find their way from Germany to Italy...We here come to the heart of the matter...How comes it that we Germans must put up with such robbery and such extortion of our property at the hands of the pope... If we justly hand thieves and behead robbers, why should we let Roman avarice go free? For he is the greatest thief and robber that has come or can come into the world, and all in the holy name of Christ and St. Peter. Who can longer endure it or keep silence?”

The papal envoy, Aleander, described the anti-Catholic climate in Germany:

“...All Germany is up in arms against Rome. All the world is clamoring for a council that shall meet on German soil. Papal bulls of excommunication are laughed at. Numbers of people have ceased to receive the sacrament of penance... Martin (Luther) is pictured with a halo above his head. The people kiss these

pictures. Such a quantity has been sold that I am unable to obtain one... I cannot go out in the streets but the Germans put their hands to their swords and gnash their teeth at me...”

What had started as a simple debate over Church practices was quickly becoming an open challenge to papal authority. The Hapsburg emperor, Charles V, needing Church support to rule his empire, was afraid that this religious turmoil would spill over into political turmoil. Therefore, although religiously tolerant by the day's standards, Charles felt he had to deal with this upstart monk. A council of German princes, the Diet of Worms, was called in 1521. At this council, the German princes, opposed to the growth of imperial power at their expense, applauded Luther and his efforts. As a result, Charles had to summon Luther to the diet so he could defend himself.

Luther's friends, remembering Jan Hus' fate, feared treachery and urged him not to go. But Luther was determined to go “*though there were as many devils in Wurms as there are tiles on the roofs.*” His trip to Worms was like a triumphal parade, as crowds of people came out to see him. Then came the climactic meeting between the emperor and the obscure monk. Luther walked into an assembly packed to the rafters with people sensing history in the making. A papal envoy stood next to a table loaded with Luther's writings. Asked if he would take back what he had said and written, Luther replied:

“Unless I am convinced by the evidence of Scripture or by plain reason—for I do not accept the authority of the Pope, or the councils alone, since it is established that they have often erred and contradicted themselves—I am bound by the scriptures I have cited and my conscience is captive to the Word of God. I cannot and will not recant anything, for it is neither safe nor right to go against conscience. God help me. Amen.”

Having defied Church and empire, Luther was hurried out of town where he was “ambushed” by his protector, Frederick of Saxony, and hidden in Wartburg castle to keep him out of harm's way. However, although Luther dropped out of sight for a year, the Reformation did not go away.

Luther's religion. Because of his criticism of papal authority and Church practices, Luther had been excommunicated from the Church. This along with the dramatic meeting at Worms led him to make a final break with the Catholic Church and form Lutheranism, the first of the Protestant faiths. This was not a new religion. It had basically the same beliefs about God as the Catholic faith. However, there were four main beliefs in the Lutheran faith that differed substantially from Catholicism.

1) Faith alone can gain salvation. No amount of good works can make any difference because man is so lowly compared to God. In the Catholic faith, penance and good works are important to salvation.

2) Religious truth and authority lie only in the word of God revealed in the Bible, not in any visible institutions of the Church. This largely reflects what Wycliffe had said about the many institutions and rituals the Church valued. As a result, Lutheranism tended to be simpler in practice than Catholicism.

3) The church is the community of all believers, and there is no real difference between priest and layman in the eyes of God. The Catholic Church gave greater status to the clergy who devoted their lives to God.

4) The essence of Christian living lies in serving God in one's own calling. In other words, God sees all useful occupations, not just the clergy, as valuable. This especially appealed to the rising middle class whose concern for money was seen as somewhat unethical by the Medieval Church.

The spread of Lutheranism. When the Church burned 300 copies of Hus' and Wycliffe's writings in the early 1400's, this dealt a heavy blow to the Hussite movement. However, from the start of the Reformation, printed copies of Luther's writings were spread far and wide in such numbers that the movement could not be contained. By 1524, there were 990 different books in print in Germany, 80% of which were by Luther and his followers, with some 100,000 copies of his German translation of the Bible in circulation by his death. Comparing that number to the 300 copies of Hussite writings underscores the decisive role of the printing press in the Protestant Reformation.

When discussing whom in society went Lutheran or stayed Catholic and why, various economic and

political factors were important, but the single most important factor in one's decision was religious conviction. This was still an age of faith, and we today must be careful not to downplay that factor. However, other factors did influence various groups in the faith they adopted.

Many German princes saw adopting Lutheranism as an opportunity to increase their own power by confiscating Church lands and wealth. Many middle class businessmen, as stated above, felt the Lutheran faith justified their activities as more worthwhile in the eyes of God. The lower classes at times adopted one faith as a form of protest against the ruling classes. As a result, nobles tended to be suspicious of the spread of Protestantism as a form of social and political rebellion. Many Germans also saw Lutheranism as a reaction against the Italian controlled Church that drained so much money from Germany. However, many German people remained Catholic despite any material advantages Lutheranism might bestow. For both Catholics and Protestants, faith was still the primary consideration in the religion they adopted.

Lutheranism did not win over all of Germany, let alone all of Europe. Within Germany, Lutherans were strongest in the north, while the south largely remained Catholic. However, Germany's central location helped Protestants spread their doctrine from Northern Germany to Scandinavia, England, and the Netherlands.

The Reformation and Women. The Protestant Reformation was a mixed bag as far as women's status was concerned. On the one hand, it encouraged literacy in women, since they too should read the Bible. Also, Luther's doctrine of the spiritual equality of all believers would spill over into ideas about social equality as well. Thus Protestant countries, such as Great Britain and the United States, would be among the first to give women the vote in the twentieth century. On the other hand, since Protestants didn't believe in a celibate clergy, they closed monasteries and convents, thus depriving women of the one alternative to living under the authority of men. Similarly, the Reformation's abolition of the veneration of saints eliminated the single most important source of role models for women. However, overall the Protestant Reformation

seems to have helped open the way for women in the future.

Luther's achievement. Although Luther had not originally intended to break with Rome, once it was done he tried to keep his religious movement from straying from its true path of righteousness. Therefore he came out of hiding to denounce new more radical preachers. He also made the controversial stand of supporting the German princes against a major peasant revolt in Germany in 1525, since he saw the German princes' support as vital to the Reformation's survival. This opened him to attacks by more radical Protestants who saw him as too conservative, labeling him the "Witternburg Pope". However, as the Protestant movement grew and spread, it became increasingly harder for Luther to control.

Martin Luther died February 18, 1546 at the age of 63. By this time events had gotten largely out of his control and were taking violent and radical turns that he never would have liked. Ironically, Luther, who had started his career with such a tortured soul and unleashed such disruptive forces on Europe, died quite at peace with God and himself. Like so many great men, he was both a part of his times and ahead of those times, thus serving as a bridge to the future. He went to the grave with many old Medieval Christian beliefs. However, his ideas shattered Christian unity in Western Europe, opening the way for new visions and ideas in such areas as capitalism, democracy, and science that shape our civilization today.

Young Luther

Martin was a bright and hard working pupil. At age fourteen he gained admission to the Latin High School at Magdeburg, sixty miles from his home. It was here that he probably had his first opportunity to read a Bible. A year later, his father transferred him to a school in Eisenach, where a rich and pious young woman, Mrs. Ursula Cotta, took interest in him, giving him free lodging, while he received free meals in another house in return for tutoring a young child of the family. Luther was now free to devote more time to his studies. Since the Cottas were a cultured family, Luther gained an appreciation of the arts and especially developed a remarkable

talent for music. Some of the hymns he composed are still sung in Lutheran churches to this day.

Even worse than the corporal punishment that Luther and other students typically endured was the horrifying sense of guilt they were taught as young children and the eternal fires of Hell they would suffer if they weren't good Christians. Of course, small children are not psychologically prepared to process such a message except on the most basic and immediate level. As a result, Christianity became for many people a continuous source of terror that smothered its gentler and more enlightened aspects. Later, as an Augustinian monk, Luther virtually tortured himself to relieve this horrible sense of guilt, starving and beating himself and even lying in the snow. As he himself put it:

"I was a pious monk, and so strictly observed the rules of my order that...if ever a monk got into heaven by monkery, so should I also have gotten there...If it had lasted longer I should have tortured myself to death with watching, praying, reading, and other work."

Luther's mission to Rome.

In 1510, Luther was sent to Rome on Church business, where he performed all the duties of a pilgrim: visiting relics and churches, climbing the Scala Sancta (sacred steps) on his knees while repeating a prayer on each step. He earned so many indulgences that he "almost wished his parents were dead so that he might deliver them from purgatory." Years later, he recalled, with some exaggeration, the sinfulness of the Roman clergy, claiming the papal court was being served supper by twelve naked girls, although he probably had no access to watch the Pope eat his meals.

Luther also claimed the Italian clergy looked down on German clergy because they could recite four times as many masses a day as their German counterparts and collect four times the fees as a result. Not surprisingly, he came away from Rome with an overall negative view of the papal city.

Purgatory and Indulgences

In the Catholic faith, Purgatory was where Christians who were saved would go to be purged or cleansed of their sins before being admitted into heaven. (Those not in a state of grace would go directly to Hell, there being no point in sending them to a temporary place of punishment when an eternity of punishment already awaited them.) Although it has never been officially designated as a place in Church doctrine, it has popularly been conceived as such. Probably the most famous description occurs in Dante's *Purgatorio*, the second part of his *Divine Comedy*, where the author describes it as a mountain in the southern hemisphere where people ascend through various levels until they reach the top and they are purified.

The amount of time spent in Purgatory was also a matter of great concern to many Christians, with estimates soaring into the hundreds of thousands of years. For example, a prayer roll of Henry VIII claimed that saying five *Pater Nosters*, five *Ave Marias* and one *Credo* reduced one's time in purgatory by "52,712 years and 40 days.

Catholic theology also believes in indulgences, which are full or partial remission of temporal punishment for sins after doing confession and penance for those sins. Medieval Christians' belief that much of their punishment would take place in Purgatory added to their distress. A major turning point came with the preaching of the First Crusade at the Council of Clermont in 1095 when by Pope Urban II offered a plenary indulgence (total remission of penance for all sins) to Crusaders who made the long and arduous trip to Jerusalem.

Indulgences could also be bought, the logic being that giving money to the Church sanctified that money and was deserving of indulgences. Backing up the Church's issuing of indulgences, as with bank notes, was the concept of the Treasury of Merits, first proposed around 1230. According to this doctrine, Christ and the saints had built up an

infinite number of merits, which the Church could draw upon and issue as indulgences. This gave it a virtual blank check for issuing indulgences and encouraged widespread and growing abuses.

Although the Church officially issued indulgences worth only 40 days, unscrupulous salesmen, often selling forged indulgences, claimed theirs were worth hundreds and even thousands of years. Some even claimed that their indulgences would save their buyers from eternal damnation, while John Tetzel claimed their purchase would turn the surrounding hills into silver.

Raphael's portrait of the Medici pope, Leo X, who authorized the indulgence sale that triggered the Reformation

Frederick of Saxony (1486-1525), who ironically would become Luther's primary protector, offered possibly the best deal anywhere. His museum of 17,443 relics supposedly included part of Christ's beard, a piece of bread from the Last Supper, twigs from Moses' burning bush, 35 pieces of the true cross, parts of Jesus' cradle and swaddling clothes, and the Virgin Mary's milk. A pious person doing reverence to each of these could earn according to different accounts 127,779 years and 116 days or 1,902,202 years & 270 days out of Purgatory.

Although the Council of Trent (1545-63) reaffirmed the value of indulgences, Pope Pius V outlawed any sales of indulgences in 1567.

Three Main Players of the Early Reformation

John Tetzel (1465-1519) was a Dominican preacher of some renown before Luther took him on. In fact he earned his doctorate the

year after Luther posted his Ninety-five Theses by defending the doctrine of indulgences in two disputations. In 1509 he had also been made an inquisitor before his appointment in 1517 to oversee all indulgence sales in Germany. The outbreak of the Reformation led to Tetzel getting a lot of bad press, often of questionable accuracy, from Karl von Miltitz who may have invented charges such as Tetzel telling people they could use indulgences to get out of punishment for sins they wished to commit in the future. Thanks, to Miltitz and others, Tetzel died worn out and broken, his reputation destroyed, in a monastery in Leipzig in 1519, less than two years after Luther posted his Ninety-five Theses.

Ironically, on his deathbed Tetzel received a letter from Luther that graciously stated that the child had another father (i.e., the Church, not Tetzel, had started the indulgence scandal).

Frederick of Saxony (1486-1525), Luther's overlord, became elector in 1486. He supported Church reform, which he urged upon the emperor Maximilian. In 1502, he founded the University of Wittenberg, where Martin Luther and Philip Melanchthon taught.

Frederick's museum of 17,443 relics supposedly included part of Christ's beard, a piece of bread from the Last Supper, twigs from Moses' burning bush, 35 pieces of the true cross, parts of Jesus' cradle and swaddling clothes, and the Virgin Mary's milk. A pious person doing reverence to each of these could earn according to different accounts 127,779 years and 116 days or 1,902,202 years and 270 days out of Purgatory. Therefore, to protect his own racket, Frederick kept Tetzel out of his lands. Ironically, he would become Luther's primary defender against the Church.

Albrecht of Brandenburg. Although Frederick closed his lands to indulgence sales, his neighbor, Albrecht of Brandenburg, did let Tetzel in for some very non-religious reasons. Albrecht owed 20,000 ducats to the Fugger banking family for buying the office of Archbishop of Mainz, which also gave him one

of the seven imperial electoral votes. Since he was already archbishop of Magdeburg as well as the administrator of Halberstadt since 1513, and therefore ineligible to hold a second (or third) church office without special papal dispensation, the pope was able to put pressure on him through the Fuggers to let Tetzel into his lands. This is how and where the good people of Wittenberg got the indulgences they showed to Luther.

By the way, Albrecht rounded out his church career in 1518 by becoming a Cardinal-Priest.

Samhain and the Origins of Halloween

Halloween, more properly the Hallowed Eve of All Saints' Day (November 1 on the church calendar) was supposedly the last day before the saints purged the world of its demons, thus its association with witches, goblins, and tooth decay. Its likely origins were a Celtic festival known as *Samhain*, meaning summer's end. The Celtic year was divided into a light half and a dark half, and Samhain was the cusp between the two. It was believed the boundary between this world and the Otherworld was especially thin on that day, allowing spirits both good and bad, to cross over into our world. Thus the purpose of Samhain was largely to ward off evil spirits, often by wearing masks and costumes to scare them.

Trick or treating probably originated in medieval England and Ireland, where people would go from door to door on Hallowmas (November 1) begging for food in return for prayers for the souls of the dead on All Souls Day (November 2).

The birth of political cartoons

Maybe even more effective than the printed word in affecting public opinion was the printed image, in particular "political cartoons". Meant to sway public opinion, they often did so by stretching or distorting the truth in ways that would seem very familiar to us today. One such cartoon (below) showed Frederick of Saxony dreaming of Luther writing his 95 Theses with a quill reaching all the way to Rome. In the distance is Jan Hus'

execution. A swan in the foreground symbolizes Luther's piety and purity. Another showed Luther as a German knight defending the true faith with a sword in his hand and the Bible at his side.

The medium would get much looser with the truth than that, however. Another cartoons portrayed the pope and Franciscan friars (a popular target of derision) as bloated from the excesses of corruption and suffering eternal damnation in Hell. The pope was also portrayed as a demon or the Anti-Christ.

Although the Protestants made wider use of such propaganda, the Catholic Church also smeared Luther, showing him as a 7-headed beast or as a bagpipe being played by Satan.

Luther's Final Break with the Church (1518-21) anti-papal rhetoric became increasingly bolder and more violent, Pope Leo X decided to act. In October 1518 he sent his papal envoy, Cardinal Cajetan, to meet with Luther. Despite his rhetoric, Luther was still deferential to the Church, even prostrating himself before the cardinal when they met. But he was disappointed that he was only expected to retract his views without having a chance to defend them. Therefore, in defiance of papal orders, Luther engaged Cajetan in three days of theological debate that got nowhere. Several

nights later, Luther's friends, fearing for his life, grabbed him and got him out of town.

Luther, remembering Hus' fate, refused an invitation to go to Rome. But in a later debate with another renowned theologian, Johann Eck, he admitted that he agreed with many of Hus' points and thought the Council of Constance had been wrong to burn him. Agreeing with a condemned heretic gave the Church further grounds for excommunicating him. When the bull of excommunication came in September 1520, Luther publicly burned it, ensuring his final break with the Church.

The problem was that the Church needed the secular authority of the emperor in order to seize Luther. The emperor at the time was Charles V, who had just won (i.e., bought) the throne of the Holy Roman Empire.

In 1519, when emperor Maximilian I died, his grandson Charles V (above) inherited all the Hapsburg family lands. However, he had to secure the throne to the Holy Roman Empire through election held by seven electors. It was a contentious election, both Henry VIII of England and Francis I of France also wanting the crown. Henry, seeing his chances as too slim and the price as too steep, dropped out.

But Francis was a more formidable candidate, and Charles only won after getting loans amounting to of 852,000 guilders, 544,000 of that from the Fugger banking family of Augsburg, to use as bribes to secure his election. Naturally, after paying such a hefty price, Charles wanted more for his money than a realm being torn apart by religious conflict. As the papal legate Aleander put it:

"All Germany is up in arms against Rome. All the world is clamoring for a council that shall meet on German soil. Papal bulls of

excommunication are laughed at. Numbers of people have ceased to receive the sacrament of penance...Martin is pictured with a halo above his head. The people kiss these pictures. Such a quantity has been sold that I am unable to obtain one...I cannot go out in the streets but the Germans put their hands to their swords and gnash their teeth at me..."

Therefore, Charles had to settle the issue of Luther before it got anymore out of hand. Bound by an agreement with the German princes, he summoned Luther under a safe conduct to the Diet (parliament of German princes) being held in the city of Wurms.

Luther's friends, remembering Jan Hus' fate, feared treachery and urged him not to go. But Luther was determined to go *"though there were as many devils in Wurms as there are tiles on the roofs."* His trip to Wurms under the protection of an imperial herald sent by Charles, was like a triumphal parade, as crowds of people came out to see him.

Then, in Wurms, came the climactic meeting between the emperor and the obscure monk. Luther walked into an assembly packed to the rafters with people sensing history in the making. A papal envoy stood next to a table loaded with Luther's writings. Asked if he would take back what he had said and written.

At first, Luther wasn't quite so fearless and defiant as history remembers him. When asked if he would recant what he had said and written, he had a temporary failure of nerve and asked if he could have some time to consider his answer. He was given 24 hours. By the next day, the crowds a people anticipating history in the making had grown so much that the meeting had to be moved to a larger hall. It was then, in front of a much larger audience, that he defied Church and state with his famous statement:

"Unless I am convinced by the evidence of Scripture or by plain reason—for I do not accept the authority of the Pope, or the councils alone, since it is established that they have often erred and contradicted themselves—I am bound by the scriptures I have cited

and my conscience is captive to the Word of God. I cannot and will not recant anything, for it is neither safe nor right to go against conscience. God help me. Amen."

Having defied Church and empire, Luther was hurried out of town where he was "ambushed" by his protector, Frederick of Saxony, and hidden in Wartburg castle to keep him out of harm's way. While in hiding, Luther, now severed from the Catholic Church and his monastic vows, grew out his hair and beard and assumed a new pseudo-identity as Junker (Knight) George (below), even though he was an animal rights activist bitterly opposed to hunting, and refused to take part in the nobles' customary rabbit chases. Supposedly, he would go out in this disguise to talk to people and get a sense of what was happening in the world, especially with his Reformation.

Luther, Satan, and the Bible

Luther's religion, while pointing toward the modern world, was still very medieval in many ways. He continued to hold to the old medieval view of Christ as an avenger despite his doctrine of faith as a free gift of God. Along those lines he believed that "few are saved, infinitely many are damned."

Luther also believed in the constant presence of Satan, having conversed with him many times, either charming him with a flute or scaring him away with foul names. Supposedly he even would throw excrement at him. At night would awaken to the creaking of walls from the cold outside, would conclude it was only Satan and go back to sleep. He also believed in demons and witches, which should be burned.

On the other hand, for the sake of his children, he said there were puppies in Heaven. He even admitted on occasion that he knew little about

God. Luther was also known for his sharp sense of humor. Once, when pestered about what God was doing before creation, he finally replied: "*He was building Hell for such presumptuous, fluttering, and inquisitive spirits as you.*"

Besides Luther's four main points of difference with the Catholic Church, there were other changes as well, largely based on Wycliffe's idea that if it wasn't in the Bible, it should be abolished. For example, the Catholic Church had seven sacraments, ceremonies considered essential to salvation: baptism, confirmation, holy communion (AKA the Eucharist), confession and penance, marriage, holy orders, and last rites (AKA extreme unction or the Anointing of the Sick). Luther kept only baptism and communion, since he saw no biblical evidence of the others taking place or assuming special importance in Christ's ministry. Later, he did reinstate marriage as a third sacrament.

One of Luther's most important and provocative actions was translating the Bible into the vernacular so all could read the word of God. His translation of the Bible into German was considered a major event in the history of the German language, much like the King James Version of the Bible has been with English.

Luther kept some aspects of Catholicism that later Protestants would do away with. For one thing, he sided with the Church's on transubstantiation (the belief that the bread and wine in communion literally transform into Christ's body and blood). Being a music lover, he also kept music in the church service, although there is no biblical reference to Christ singing.

Timed sermons. The requirements for a Lutheran minister were quite demanding, in terms of education, so they knew scripture well, and preaching. Lutheran ministers were expected to deliver 200 sermons a year, including two each Sunday. They had hourglasses next to the pulpit, not to keep them

from running too long, but to make sure they gave sermons of at least a minimal length.

The Perils of Womanhood in Early Modern Europe

Despite any benefits the Reformation may have brought women, they still were highly vulnerable to abuse and harassment from men. This was especially true for young women from poorer urban families that hired themselves out as domestic servants to the families of the rich. Being at a disadvantage because of both their gender and social class, their employers would often force them into compromising sexual situations. If they refused to cooperate, they would be fired. If they complied and got pregnant, they were also fired.

In the middle ages, the Church had sanctioned and even encouraged secret marriages done without the parents' knowledge and permission. While this enhanced the power of the Church, such secret marriages often left open the question of whether a pregnant woman was actually married to the father, since there were no witnesses. The man could either admit to being married to her, and thus be married by law, or he could deny being married and face punishment as a fornicator. Many men preferred the latter option, despite the stigma and the requirement of paying a "second dowry" as compensation to the mother. This was typically twice the value of her regular dowry, since she was now considered less marriageable. In disputed cases, women were usually assumed the innocent party, having been seduced into the relationship. To counter secret marriages and the promiscuity they both encouraged and masked, towns started requiring public weddings before witnesses.

Another problem was the large number of single young men, since they couldn't get married until they could support a family. As a safe outlet and to protect young women, late medieval towns often ran public brothels. However, the spread of syphilis after 1500 and tighter moral standards resulting from both the Protestant and Catholic Reformations led

to such institutions being shut down in the 1500s.

Therefore, young women still had to be extremely careful, which inspired this testament from a dying mother to her daughter in the 1600s: *“Don’t eat and drink too much at parties. Eat and drink ahead of time and accept drinks only from other girls. If a boy peels a fruit for you, do not accept it. When boys come and sit beside you, don’t answer their questions; say only “yes,” “no,” and “I don’t know.” And do not smile at them. When boys happen to come into your bedroom, hide behind the bed and threaten to hit them in the face.”*

The German Peasants Revolt (1524-5)

“When Adam delved & Eve span/
Who then was the gentleman?”
--John Ball*

**Delved and span: Middle English terms for plowing without the aid of a draught animal and for spinning wool.*

Although Luther spoke of equality in purely spiritual terms, many poor people took it to mean social and political equality as well. Not that this was a wholly new idea. It was most notably expressed in the above poem by John Ball, a Lollard leader of the Wat Tyler Rebellion in 1381.

In other words, when Adam and Eve were the only people, there were no social classes. Thus social classes were not divinely ordained and all people should be equal in status. In an era when religion and politics were inseparable, such an idea, fused with Luther’s Reformation, could prove a most volatile fuel during a popular uprising, such as the German Peasants’ Revolt in the 1520s.

The German Peasants’ Revolt (1524-5). The 1500s were a time of rapid economic change. As more money entered the economy, peasants, (i.e., the 85-90% of the people who made their living from the less dynamic agricultural sector) felt the squeeze of rising rents charged by landlords who were also trying to keep up with inflation and the progressively weaker buying power of the money they got for their crops. In 1524, a peasant revolt suddenly erupted and spread across Germany.

Peasant revolts followed a fairly typical pattern. They would start spontaneously, catching the authorities off guard and thus initially spread rapidly across the countryside. Years of frustration would be unleashed on any nobles and clergy the peasants captured, whatever atrocities they committed being magnified tenfold by rumor and fear.

However, while the revolt’s spontaneous nature might have helped it at first, it eventually would be its undoing, because it wasn’t organized into a well trained army. By contrast, the nobles the peasants were rebelling against were professional warriors. Once the initial shock of the revolt had worn off, the nobles would pull together a real army and go after the rebels. When the two forces met, the rebels, with little or no military organization or training, would usually panic and run at first contact with the nobles, and the rebellion would be crushed as suddenly as it erupted. Vengeance for peasant atrocities, real or imagined, would be extremely severe in order to discourage any future thoughts of rebellion.

Complicating the German Peasant Revolt was the fact that, since religion and politics were so intertwined, peasant converts to Lutheranism might also use it to justify political revolution. Reinforcing this idea was the fact that several leaders of the Peasants’ revolt were Lutheran preachers, most notably Thomas Muntzer.

Against the Murderous, Thieving Hordes of Peasants (1525) was Luther’s response to the Peasant revolt. One wonders how much this reflected his real views and how much of it

reflected the pressure to distance himself and his Reformation from the revolt in order to keep the crucial support of the German nobles:

“First they have sworn to their true and gracious rulers to be submissive and obedient, in accord with God's command (Matt. xxii. 21), ‘Render therefore unto Caesar the things which are Caesar's,’ and (Rom. xiii. 1), ‘Let every soul be subject unto the higher powers.’ Wherefore St. Paul judges them, saying (Rom. xiii. 2.), ‘And they that resist shall receive to themselves damnation.’ The peasants will incur this sentence, sooner or later; for God wills that fidelity and allegiance shall be sacredly kept....

“Rebellion is not simply vile murder, but is like a great fire that kindles and devastates a country; it fills the land with murder and bloodshed, makes widows and orphans, and destroys everything, like the greatest calamity. Therefore, whosoever can, should smite, strangle, and stab, secretly or publicly, and should remember that there is nothing more poisonous, pernicious, and devilish than a rebellious man. Just as one must slay a mad dog, so, if you do not fight the rebels, they will fight you, and the whole country with you.”

The *bundschuh* that peasants wore was popular symbol for rebelling peasants, *bund* referring to the shoe's leather bindings, thus implying the idea of “union”.

The German Peasant Revolt was the third most destructive event in German history, only exceeded in material damage by World War II and the 30 Years War. (World War I being fought almost exclusively in other countries, it did little material damage to Germany.)

The Reformation Starts Spinning out of Control
As the Reformation spread, it also got increasingly out of control. In towns across Germany, including Wittenberg, crowds rioted against the Catholic Church, smashing and whitewashing icons, attacking priests, and turning monks and nuns out into the streets as they took over monasteries and convents.

At Erfurt, just two months after the Diet of Worms, students, artisans, and peasants attacked and demolished 40 parish houses, destroying libraries and rent rolls. In August Friars there were denouncing the Church and by autumn were preaching Lutheran doctrine.

Much of Luther's early support came from a younger generation of preachers frustrated with Rome's patronizing response to the 95 Theses. In towns that refused to silence them, they would generate public discussions that often turned into arguments and even violence. These would lead to petitions to the town council to abolish the Catholic mass, often leading to even more violence.

Eventually the mass would be replaced with a simpler service with the congregation singing (instead of just the clergy) or banning music altogether (since it wasn't in the Bible). The clergy, now paid by the state, were expected to get married, since Christ didn't dictate a celibate clergy. Monasteries were turned into state property or given to charity, the monks and nuns being turned out into the streets. About half of Germany's monasteries were willingly or forcefully emptied in such a way.

As a result, churches across Germany were being transformed from being parts of an international hierarchy to becoming self-regulating departments of the local political communities, at first at the level of towns and villages, and eventually entire principalities as rulers joined the reform movement.

However, without Luther's guiding hand, many communities went much further than he had intended. For example, at Zwickau, a firebrand preacher, Thomas Munzer, influenced by more radical Taborites (Hussites), engineered an unsuccessful revolt and was driven out of town. After much wandering, Munzer ended up leading a peasant revolt in Thuringia where he was defeated, tortured, and executed.

However, he had influenced one of Luther's followers, Andreas Carlstadt, who believed in

the impending Millennium (apocalypse) and the need to destroy books and exterminate the upper classes. Carlstadt's followers forced the municipal council of Wittenberg to ban all religious images and replace the Catholic mass with a much simpler service with bread and wine for all. They tore images down from church walls and pelted priests with stones. Believing Munzer's idea that God speaks directly to men, especially simpler ones, Carlstadt preached against learning and books, causing many students to give up school and take up farming or handcrafts.

Luther, alarmed by this news, came out of hiding in 1522 to bring Wittenberg to its senses. In a series of eight dramatic sermons, he restored a tolerant religious climate between Protestants and Catholics. Carlstadt fled to Orlamunde where, as Brother Andreas, he preached more radical Old Testament practices, including polygamy, while earning his living behind a plow. When Luther went there to preach against him, he was pelted with stones and mud and driven out of town. With the collapse of the Peasants' Revolt, Carlstadt straightened up and lived as a University professor at Basel until his death in 1541.

Luther's family life

Marriage came largely as an afterthought to Luther and as a concession to his own disapproval of a celibate clergy, since in the Old Testament God had told people to be fruitful and multiply. His wife, Katherine Bora, was a former nun who had become drawn to Luther's doctrine of faith alone. To avoid an angry mob outside the convent, she and eight other nuns escaped, reportedly hidden in herring barrels on a wagon.

Luther spent much of his own time and money helping former monks and nuns in the transition to living in mainstream society. Although he considered Katherine arrogant and tried to match her with several different men, he ended up marrying her, supposedly because all the other escaped nuns were already married and he thought he should set an example of marital bliss for other ministers.

Although he seems to have married as an afterthought, he grew to love her and it was a happy union. Luther considered sexual method of human reproduction as absurd. He apparently knew what he was talking about, because he and Katie had six children. As he put it: "*...had God consulted me in the matter, I should have advised him to continue the generation of the species by fashioning human beings out of clay, as Adam was made.*"

Luther encouraged a healthy sex life within marriage as a means to keep men from straying outside of marriage. Ironically, he said it was all right for a wife to take another lover if her husband couldn't satisfy her and that her husband should agree to this. Then again, Luther would tease his wife by saying a man should have more than one wife since he can beget many children in a short time while she can only bear one child per year.

In addition to their six own children, they adopted 11 more and usually had up to twelve students boarding with them, thus creating a full household to support. Since Luther refused to take money for his religious services, Katie's organizational skills kept his household running, freeing him for less mundane affairs. Luther did help support his family through gardening. He was reputedly an excellent gardener who raised championship-sized lettuce. The Luthers' home in Wittenberg was a former Augustinian cloister given to Martin and Katie soon after their marriage.

Luther died in 1546 from complications of a cold after traveling through some bad weather to tend to a sick friend. His life and work formed a bridge between the medieval and modern worlds and triggered changes he never could have dreamed of.

When I die, I want to be a ghost...So I can continue to pester the bishops, priests and godless monks until they have more trouble with a dead Luther than they could have had before with a thousand living ones.--Martin Luther

The Reformation Fragments (1518-1560)

Introduction. While the Catholic Church kept Western Europe religiously united for 1000 years, Protestant unity broke up almost immediately. There were three major reasons for this. First, Luther's successful challenge to the Catholic Church set an example for other reformers to follow. Second, the printing press and translations of the Bible from Latin to the vernacular let more people read and interpret scripture on their own. Previously, the Church's monopoly on Bibles, all written in Latin, severely limited individual interpretations. Finally, the Bible itself is often vague, which also encouraged widely differing interpretations. Consequently, a number of different *sects* (religious groups) sprang up on the heels of Luther's Reformation.

Huldreich Zwingli and the Swiss Reformation. The first break in Protestant unity came from the Swiss reformer, Huldreich Zwingli. Although only a year younger than Luther, Zwingli seemed to come from a different world. While Luther's outlook and background were very medieval, Zwingli received a liberal humanist education and did not have the great sense of guilt and fear of the terrors of hell his German counterpart had. Zwingli's humanist education influenced him to call for a religion based entirely on the Bible. In 1518 he became a common preacher in Zurich, Switzerland and echoed Luther by speaking out against Bernhardin Samson, a local seller of indulgences. He also denounced other church abuses and thus launched the Swiss Reformation.

Zwingli's religion was both similar to and different from Luther's. Like Luther, he stressed a more personal relationship between man and God, claimed faith alone could save one's soul, and denied the validity of many Catholic beliefs and customs such as purgatory, monasteries, and a celibate (unmarried) clergy. However, Zwingli's goal from the first was to break completely from the Catholic Church. His plan for doing this was to establish a theocracy (church run state) in Zurich.

By 1525, he had accomplished this, having banished the Catholic mass and introduced services in the vernacular. He vastly simplified the service to sermon and scripture readings. Despite his love of music, Zwingli banned it from the service and even smashed the church organ. He either destroyed or whitewashed religious images, which he saw as idolatrous, served communion in a wooden bowl rather than a silver chalice, and closed down monasteries or turned them into hospitals and schools. While not persecuted, Catholics had to pay fines for attending mass and eating fish on Fridays (a Catholic practice then to symbolize personal sacrifice by not eating meat) and were excluded from public office. Zwingli also closely supervised the morals of his congregation. All these measures anticipated the later reforms of John Calvin.

By 1528, Zwingli's reforms had spread across northern Switzerland with the South remaining Catholic. Because of fear of being caught between Catholics in southern Switzerland and Germany to the north Zwingli followed a more aggressive foreign policy and attempts to unite with the Lutherans in common cause against the Catholics. The proposed alliance never occurred because the two camps could not agree on one piece of theology: whether the bread and wine of communion were actually *transubstantiated* (transformed) into the body and blood of Christ. The Catholic Church had claimed for centuries that transubstantiation did take place, and Luther agreed with them in a modified form. Zwingli said it was only symbolic of Christ's body and blood. A personal meeting between Luther and Zwingli in 1529 accomplished nothing except hard feelings, and the proposed alliance between the Zwinglians and Lutherans fell through.

Aggressive Zwinglian missionaries in the Catholic districts of Switzerland led to war in 1531, and an army of 8000 Catholics destroyed Zwingli and his force of 1500 men. An uneasy co-existence between Protestants and Catholics followed, and Protestantism survived in Switzerland. Zwinglianism, however, did not survive, being replaced by Calvinism in the Swiss Reformed Church. Still, Zwingli was important for establishing Protestantism in Switzerland and serving as an example for the more successful Calvinists who followed.

Grassroots Protestantism: the Anabaptists. After breaking the Catholic Church's centuries-long monopoly on religion, the issue arose of how far beyond the old set of rules the new beliefs could go. Luther, Zwingli, and Calvin, despite significant religious differences, drew up new sets of rules fairly close to the Catholic Church's. Among other things, they all believed in obedience to civil authority. However, some men preferred to go much further in rewriting the rules. As a result, some 40 different religious sects sprang up in Western Europe. Although their beliefs varied somewhat from one another, they have been lumped together under the name of Anabaptists from their common practice of baptizing members as adults when they could make the free choice to be Christians. In addition to the Bible as a source of religious truth, they also believed in inner revelation coming directly from God.

Death for rebaptism. A common misconception about Anabaptists, which meant “rebaptists”, was they were baptized twice, once as babies and a second time as adults, when they only did it once as adults. However, rebaptism was a capital offense going back to Justinian’s law code, the reason being that to get baptized a second time implied one doubted the validity of the first ceremony, and to doubt the validity of a Church sacrament deserved death.

Anabaptists thought baptizing infants was ridiculous, since they had no idea of what was going on. They way they put it, baptizing babies was like washing cabbages in the dark.

In Appenzell, Switzerland Anabaptists, taking literally a Biblical passage about not worrying about where their food would come from, laid out tables in the streets and waited for food to drop from Heaven. It didn’t.

The Anabaptist movement was more involved with social discontent than the other Protestant sects were. The 1500's saw economic difficulties resulting from rising population and inflation. Peasants, town craftsmen, and miners were especially hard hit, and it was they who especially joined the Anabaptist ranks in hope for a better world to come. Most Anabaptists denied the right of civil governments to rule their lives. They

refused to hold office, bear arms, or swear oaths, which naturally made the authorities suspicious.

Actually, most of the Anabaptists were just trying to live good, peaceful; Christian lives in imitation of Christ himself. They did not openly resist the authorities, but they still aroused suspicion because of their different ways. Some groups held property in common. Others went to extremes in interpreting the Bible literally, preaching from rooftops and even babbling like children as the Bible supposedly told them to. They tended to separate themselves from the rest of society, which they saw as sinful. Despite their peacefulness, the Anabaptists were heavily persecuted. This forced them to migrate, which spread their beliefs from Switzerland down the Rhine to the Netherlands. It was here that the movement turned more violent as it combined frustration from economic hard times with an older tradition of socially revolutionary ideas that were popular among the peasants of the region. The climax of this process took place in the German city of Munster in the early 1530's.

It was in Munster that radical Anabaptists seized power and combined religious fanaticism with a reign of terror that tarnished the reputation of other Anabaptists for years. All books except the Bible were burned. Communal property and polygamy were enforced. Their leader, John Bockleson, ruled with a lavish court while ensuring his followers that they too would eat from gold plates and silver tables in the near future. So alarming was this spectacle that Lutherans and Catholics combined forces to snuff it out. The determined and disciplined resistance of the Anabaptists led to a drawn out siege (1534-35). The city was finally betrayed and the Anabaptist leaders exterminated. An intense persecution of the Anabaptists followed, killing thousands and driving many more from place to place. Some of them, such as the Mennonites and Amish, would find a home in North America and have had a profound influence on our attitude of separating church and state. Others made their way to the Spanish Netherlands where they helped stir up a major revolt against Catholic Spain.

The English Reformation. As discussed above, the strong medieval monarchies of France, England, and Spain assumed more and more control over the Church within their own lands. As a result, these kings had few grievances against the Church and

were generally hostile to the Reformation, since it threatened their own control of religious policies. They were also strong enough to repress the spread of Protestantism among the lower classes. However, the Reformation found a home in one of these monarchies, England, thanks to some very peculiar circumstances.

Henry VIII of England had been given the title of "Defender of the Faith" by Pope Clement VII for a work he had written attacking the Lutherans, mainly on political grounds. However, just as at one point Henry defended the Church for largely political reasons, at a later date, he broke with it, also for political reasons.

Henry had a problem: he needed a son to succeed him to the throne. Without such a son, England might plunge back into civil war like the Wars of the Roses that Henry's father had ended in 1485. Henry's wife, Catherine of Aragon, had borne him a daughter, Mary, but no sons. Since Catherine was getting older, Henry wanted his marriage annulled so he could find a new wife to bear him a son. Unfortunately, Catherine was the aunt of the Hapsburg emperor, Charles V. Naturally he wanted Catherine to remain as Queen of England in order to influence its policies and possibly get control of the throne herself. Since Charles also controlled the pope, the annulment was refused. Meanwhile, Henry had "fallen in love" with a young woman of the court, Anne Boleyn, giving him even more reason to dispose of Catherine.

Only twenty years earlier, Henry would have had to accept this verdict or resort to violent means to solve his problem. Ironically, the Lutherans that Henry despised provided him with an answer to his problem: break with Rome. However, he had to move quickly, because Anne was with child and Henry wanted the baby, hopefully a boy, to be born after the break with Rome in order to be legitimate.

In 1533, Henry started to break England's ties with the Catholic Church. He was clever in how he did this, doing it in stages, first by cutting off money to Rome, then curtailing the power of the Church courts and assuming more authority over the English clergy. Also, he did this through Parliament to make it seem the will of the English people rather than the mere whim of the king. In 1534, he severed the last ties with Rome, and the

Church of England replaced the Catholic Church. All this took place in time for the birth of the baby, which turned out to be a girl, Elizabeth.

The average churchgoer in England would have noticed little difference in the dogma and service as a result of this break, since the Church of England was basically the Catholic Church without a pope. Therefore, most people accepted it because they resented Church abuses, feared a civil war if Henry died without a male heir, and there were no drastic changes.

After Henry's death, his nine-year-old son, Edward VI, the son of Jane Seymour, one of Henry's later wives, took the throne. During his brief reign, the nobles ruling in his name followed Protestant policies. However, when Edward died in 1553, his older half sister, Mary, came to the throne. Like her mother, Catherine, she was an ardent Catholic, even marrying her cousin Philip II of Spain to enforce her Catholic policies. The main effect of Mary's persecution of Protestants was to alienate the English People, make them more firmly Protestant, and earn her the title of Bloody Mary.

When Mary died childless in 1558, her half sister, Elizabeth I, succeeded her. This remarkable woman, one of England's ablest and most popular monarchs, steered an interesting course between Protestantism and Catholicism. The English, or Anglican, Church under Elizabeth grafted moderate Protestant theology on top of Catholic organization and ritual. This compromise satisfied most people, although the more radical English Calvinists wanted more sweeping reforms, such as doing away with bishops and archbishops altogether. These people, known as Puritans, wanted to purify the Anglican Church of all Catholic elements. Their numbers and power would continue to grow throughout Elizabeth's reign, although she was able to control them.

In addition to England's navy saving European Protestantism from extinction at the hands of the Spanish Armada in 1588, the English Reformation was important for opening the way for the more radical Puritans Calvinists to filter in. Eventually, they would become influential enough to overthrow the pro-Catholic king, Charles I, and establish a parliamentary democracy. This in turn would

inspire the spread of democratic ideals to America, Europe, and the rest of the world.

Zwingli's Reformation

Early in his career, Zwingli served as a chaplain for Swiss mercenaries in the Italian wars and witnessed the disastrous battle of Marignano where 6,000 of his countrymen died. Like many other Swiss, he was concerned about the drain of these wars on the Swiss population and campaigned against "selling blood for gold". Largely due to the attrition coming from these wars, the Swiss were replaced as the era's premier mercenaries by German *landsknechts*. However, Swiss Guard honor regiments would serve popes to the present day and French kings until the end of the monarchy in 1792.

Gold for babies. The Swiss clergy were notorious for being morally lax. When a Swiss bishop charged each of his subordinates four guilders for each illegitimate baby they had fathered, he collected 1522 guilders in just one year. (Where the extra two guilders came from is unclear.) Zwingli himself had an affair with a barber's daughter until 1516, when he ended the affair.

Earning "street cred". In 1519, plague struck Zurich, eventually killing one-third of its population. Unlike many clergy and doctors who fled the scene, leaving the sick to fend for themselves, Zwingli stayed and tended the plague's victims, which made him popular with the townspeople. It also exposed him to and infected him with the plague, which required a long period of recovery that taught him to depend on God's mercy.

A pretty smart guy. Zwingli not only read, but even memorized St. Paul's epistles. He also astounded his congregation one Sunday by doing a sight translation of the entire Gospel of Matthew. What made this especially amazing was the fact that Catholic congregations would only hear selected verses from the Bible, not entire books in context.

Stricter interpretation. Zwingli tended to be more tightly tied to scripture than Luther. One simple way to distinguish between the theologies of the two men is that, in general, Luther allowed what was not strictly forbidden in the

Bible, while Zwingli banned whatever was not explicitly allowed. He did keep stained glass windows, most likely because replacing them would be expensive and necessary, given the cold winters in that part of the world.

Fish on Fridays. Until extensive reforms in the 1960s, Catholics were not allowed to eat meat on Fridays, although they could eat fish. The reason for this was that the meat from warm-blooded animals right before the weekend could inflame the passions and make people act naughty. Such danger did not exist with fish, since they are cold-blooded.

Cuckoos and hedge sparrows. There were fifteen major points of difference between Luther and Zwingli. For example, Luther said only God knew the elect (those who were saved) while Zwingli said they were known by their public adherence to faith. Amazingly, they managed to come to agreement or some sort of compromise at the Colloquy of Marburg (1531) on all but one point: transubstantiation. Afterwards, Luther said Zwingli's symbolic interpretation of the Bible would lead him to turn a passage such as "God created the heavens and the earth" into "The cuckoo ate the hedge sparrow."

According to one version, Catholics found Zwingli already wounded after the battle and killed him when he refused to recant his beliefs.

Paradise Lost: Munster, Germany (1534-35)

Adding to the already heated religious passions of the 1530s were groups of Millennialists, people who thought the second coming of Jesus and the end of the world were close at hand. This was an especially prevalent thought in the 1530s due to a belief that Christ would be gone a thousand years but not thousands. The medieval mind being obsessed with mathematical symmetry, many thought his

return would be exactly halfway between 1000 and 2000 years, i.e. 1500 years after he left earth. The only question was exactly when that should be. People knew Christ had lived around 33 years, so different prophets declared various specific dates in the 1530s as the date of the Second Coming.

All this came together in the North German town of Munster.

Munster had seen hard times over the last decade, suffering from the Peasant revolt (1524-5), plague and famine (1529), and a huge tax for wars against the Turks (1530).

On top of this, the people of Munster were saddled with a new ruler, Prince-Bishop Franz von Waldeck (1491-1553), who had never even been ordained as a priest and kept both a wife and mistress. The prominence of his sword and armor in his portrait show the typically political nature of his position. Although as sympathetic to the Protestants as to the Catholics, he alienated both groups with his heavy taxes to cover the cost of buying his office.

This, along with plague, famine, and taxes already burdening Munster, triggered a Lutheran revolt that drove the new bishop from Munster, establishing a more tolerant religious climate.

Word of the existence of at least one haven of religious freedom opened the way for thousands of Anabaptist refugees to come flocking in and take over. In response, the bishop quickly gathered other princes, both Catholic and Lutheran, to drive the Anabaptists from Munster.

The Anabaptists put up a determined defense during the siege, strengthening their fortifications with a double moat, defensive palisades and even cannon shot emanating from the cathedral tower. This kept the Prince-bishop's forces at bay for well over a year and drove him heavily into debt.

The first Anabaptist leader, Jan Matthys, was killed following a vision that he should lead 12 followers out to drive off the entire besieging army. It didn't work. After that, a Dutch leader, Jan van Leyden (AKA John Bockleson), took over. That's when things got really crazy.

Bockleson started his reign over Munster by running through the streets in fits of religious frenzy (on one occasion naked). This stirred up a virtual hysteria, which he used to impose a reign of terror on the town. Bockleson declared Munster the New Jerusalem and himself as "King, Messiah of the Last Days". His coat of arms had a globe topped with a cross and pierced by two swords symbolizing revenge and spirit. He forcibly converted all newcomers to Anabaptism, confiscated all superfluous wealth to "be held in common", and enforced mandatory polygamy, largely because there were three times as many female refugees as men in the town.

When Henry Mollenheck, a prominent guild leader, and some 50 others rebelled against the Anabaptist leader for his decree of enforced polygamy, Bockleson had them all shot. Similarly, he executed one of his wives, Elizabeth Wandscheer, for rebelling against his authority and then celebrated with his other wives with dance and song around her body.

To break or discourage any further spirit of revolt, Bockleson had all new converts herded into the Church under armed guard and told them he would wait to see what God wanted him to do with them. After sundown and several hours of ever increasing fear, Bockleson returned and announced that God had spoken to him and commanded him to (with a pregnant pause) spare their lives. This had the desired effect.

Meanwhile the siege had been lifted, only to be replaced by a much tighter one prosecuted by a broader coalition of Catholic and Lutheran states scared of the Anabaptist hysteria spreading. As the siege intensified Bockleson's reign of terror became increasingly bizarre. While famine took its toll among the general population, he lived in increasing luxury with his court, staged lavish plays and spectacles as diversions, and prophesied God would turn the cobblestones of Münster into bread at Easter. They didn't.

To keep people on their toes, Bockleson declared at the sound of the trumpet, everyone should assemble in the square to march on Jerusalem and conquer the world, proclaiming each of them would be worth ten enemies in battle and would feel neither hunger, thirst, nor pain. Occasionally, usually in the middle of the night to generate the most fear, Bockleson would sound the trumpet. The people would assemble and he would say he was just testing them.

Finally, some disgruntled mercenaries betrayed a breach in the wall to the Prince-bishop's forces, which poured in and took the town. Bockleson and two of his followers were executed and hung in cages from the cathedral. The cages still hang there as a reminder of the madness that can affect any of us.

Because of what happened at Münster, persecution of Anabaptists intensified, driving them downriver toward the Spanish Netherlands where their presence would trigger an even more vicious round of religious violence. Ironically, all they ever wanted was peace in a peaceful land.

Some of them, led by people like Menno Simons, would find it for a while in the New World. Their idea of separation of Church and State to prevent further religious conflict would become a cornerstone of our constitution.

“Divorced, Beheaded, Died...”—Henry VIII's Complicated Love Life

Henry's legal excuse for getting his marriage to Catherine annulled was that she had been his brother's wife, there being a biblical curse of childlessness if a man married his brother's widow.

Following is a letter from Anne Boleyn to Henry, showing the levels to which a girl such as herself had to stoop to impress the king:

*“Sire,
It belongs only to the august mind of a great king, to whom Nature has given a heart full of generosity towards the sex, to repay by favors so extraordinary an artless and short conversation with a girl. Inexhaustible as is the treasury of your majesty's bounties, I pray you to consider that it cannot be sufficient to your generosity; for, if you recompense so*

slight a conversation by gifts so great, what will you be able to do for those who are ready to consecrate their entire obedience to your desires? How great soever may be the bounties I have received, the joy that I feel in being loved by a king whom I adore, and to whom I would with pleasure make a sacrifice of my heart, if fortune had rendered it worthy of being offered to him, will ever be infinitely greater.

The warrant of maid of honor to the queen induces me to think that your majesty has some regard for me, since it gives me means of seeing you oftener, and of assuring you by my own lips (which I shall do on the first opportunity) that I am,

*Your majesty's very obliged and very obedient servant, without any reserve,
Anne Bulen."*

In order to make Anne's child, who was due in September 1533, look as legitimate as possible, Henry married her secretly in January, but didn't publicly divorce Catherine until May.

Henry had the English clergy recognize him as the head of the church in England "as far as the law of Christ allows", an intentionally vague term that would give him room to maneuver.

After breaking with the Church, Henry closed and confiscated the lands of 550 monasteries in England, forcing 7,000 monks out into the world to fend for themselves. He then sold his new lands at cut-rate prices to various English nobles. Therefore, when the inevitable backlash came from the Church, the nobles were tied to Henry's interests since they wanted to keep their newly seized lands.

Anne Boleyn didn't last long after just giving Henry a girl. She was charged with adultery, which was treason when committed by a queen, because it called the legitimacy of the king's children into question, which might lead to civil war over the succession. Just to be safe, Henry also charged Anne with being a witch for having six fingers and three breasts.

An easy way to keep track of the fates of Henry's six wives (Catherine of Aragon, Anne Boleyn, Jane Seymour, Anne of Cleves, Catherine Howard, and finally, Catherine Parr) is this simple little poem:

*"Divorced, beheaded died
Divorced, beheaded survived"*

Mary's husband, Philip II of Spain, was, in the best of Hapsburg traditions, also her first cousin once removed. Ironically, as king-consort, he helped build up England's navy, the same navy that would defeat his armada thirty years later.

THE REFORMATION FRAGMENTS (2): CALVINISM

Introduction. As important as the Zwinglian, Anabaptist, and English reformers may have been, it was Calvinism that would have the most profound and revolutionary impact on Western Civilization. Although the Calvinists' primary concerns were religious, their reforms would radically alter the political and economic institutions of Europe, helping lay the foundations for the eventual triumph of capitalism and democracy.

Luther's break with the Church was especially difficult since he had grown up without any religious alternatives to Catholicism or examples to follow in his reforms. The next generation of reformers, led by John Calvin, grew up in a world that offered alternatives to Catholicism, thus making it easier to break with the Church and carry religious reforms much further than Luther ever had.

Calvin himself grew up in France as the first shock waves of the Reformation rocked Europe. Although not officially allowed in France, Protestant ideas still filtered across the border and won converts. Unlike Luther, whose tormented soul provides fascinating reading, Calvin was a much calmer individual. He seems to have been plagued by none of Luther's self doubts and his personal character was described as nearly flawless. After receiving a good education in theology, law, and also humanist studies, which prompted him to read the *Bible* more carefully, he seems to have arrived at some sort of conversion in 1533.

Calvin's religion. The cornerstone of Calvin's theology was God's all encompassing power and knowledge. There was nothing God did not know or have control of: past, present, or future. As a result, God knew and controlled from the beginning of time whose souls would be saved or condemned for eternity. This doctrine, known as *predestination*, had scriptural support and was a logical outgrowth of what Luther had said about

faith and salvation being a free gift of God. Predestination raised several disturbing questions. First of all, if God were all-powerful, could we have any free will in choosing between God and Satan? Quite bluntly, Calvin said no. Second, if God were good, how could he let evil exist in the world? Calvin answered that these were mysteries of God that we cannot know the answers to and probably have no business asking.

Finally, can we know we are saved and how? According to Calvin, there is no way for us to know for sure. However, if we meet the requirements of living an upright life, profession of faith, and participation in the sacraments, we could become pleasing to God and be saved despite our sinful nature, if predestined to do so. Such a puritan lifestyle might not ensure salvation, but it could be a sign that one *might* be one of the few elected by God to go to heaven. However, Calvin said our primary concern should not be going to Heaven, but rather carrying out God's plan for us in this life. As fatalistic as Calvinism with its denial of the existence of free will may sound, its adherents felt empowered by this idea that they were the special instruments for carrying out God's plan. This gave them an unshakable faith in the utter rightness of their cause and made Calvinism the most dynamic movement of its day.

Calvin's *Institutes of the Christian Religion*, first published in 1536 and constantly revised throughout his life, became one of the most popular and influential books of its day. However, Calvin went beyond words in trying to make a point about his religion. To ensure that as many people as possible had a chance to be saved, he established a model Church and community in Geneva, Switzerland to enforce the proper lifestyle needed for salvation. Naturally, Calvin's reforms met resistance and it took him nearly twenty years to get control of Geneva and reform it.

Although the city government still functioned, the Consistory, a church council of twelve elders, wielded the real power over people's lives in Geneva. All citizens were members of the church and had to attend services three or four times a week. This was because there was no telling who was predestined to be saved, and so all must be given a chance. Such acts as fighting, swearing, drunkenness, gambling, card playing, and dancing

were outlawed. Even loud noises and laughing in church were fined. Theaters and taverns were closed and replaced by inns allowing moderate drinking accompanied by sermons and church propaganda. Members of the Consistory would make annual inspections of homes to ensure they were morally run. People were even expected to report their neighbors for any behavior that was less than saintly.

The Consistory also ruled the more trivial aspects of peoples' lives. Jewelry and lace were frowned upon, the color of clothing was regulated by law, and women were fined for arranging their hair to immodest heights. Children were to be named after Old Testament figures, and one man was jailed for four days for naming his son Claude instead of Abraham. Punishments were equally harsh, with fifty-eight executions between 1542 and 1564, mostly for heresy (especially Catholicism) and witchcraft. Fourteen witches were burned in one year and one boy was beheaded for striking his parents. Not surprisingly Geneva was called "City of the Saints".

Geneva served as a model to other reformers in Europe, helping make Calvinism the most popular form of Protestantism in the Netherlands, Scotland, and England. This was in spite of its lack of support from rulers who feared both Calvinism's emphasis on God's absolute power, which might undercut the doctrine of Divine Right of Kings, and its lack of being associated with any particular nation. In Germany and Scandinavia, Lutheranism was quickly identified with strong nationalist sentiments that rulers could exploit for their own political purposes. However, Calvinism had no particular national ties, thus depriving it of the strong state support that Lutheranism enjoyed.

However, this lack of state support forced Calvinists to form independent local congregations without any real central organization, making it virtually impossible to uproot and destroy their movement by concentrating on a few leaders. These congregations were somewhat democratic, thus inspiring greater loyalty in all their members, even when facing intense persecution for their beliefs.

Long range effects of Calvinism. Two of Calvin's ideas would have long-term effects going far beyond religion. First, the idea of predestination

meant not only that Calvinist merchants were *allowed* to do business and make money, they were *predestined* to do so and should do so fervently as God's will. Of course, as devout Calvinists, they were to make money *for the good of the church and community*, and at first that was what they did. However, later generations, lacking the intense fervor of the first generation of reformers (a normal pattern with any revolutionary movement), came to feel justified in pursuing profits for their own personal good. The result of this was the triumph of capitalism as the dominant economic system in Western Europe, especially in England and the Dutch Republic where Calvinists predominated. This in turn would make Western Europe the economic center of the world and home of the Industrial Revolution.

The second far-reaching effect of Calvinism was the idea that God sees all useful occupations as equal that, along with the concept of God's absolute power, discredited the doctrine of Divine Right of Kings. Calvin himself preached obedience to authority unless religious conviction forced civil disobedience. But it should never involve open resistance, since God alone would punish any evil rulers. However, some Calvinists, such as John Knox, the fiery leader of the Scottish Calvinists, preached people could overthrow a corrupt prince to defend their religious beliefs and God's law. The revolt of the Spanish Netherlands (1566-1648) and the English Civil War (1642-45) were two prime examples of such Calvinist religious revolts.

Later, these two ideas, capitalism and religious revolution, combined into an even more powerful idea discussed in John Locke's *Two Treatises on Government* (1694). Much as middle class contracts define obligations in a business deal, Locke saw government as an implied contract especially defining obligations for the king who, as caretaker of the state for the good of the people, should *protect their lives, liberties, and property*. If the king failed in these duties, the contract was null and void and the people had the right to overthrow him. This combination of middle class contracts and the belief in religious revolution would become the cornerstone of democracy. And within that idea lay the seeds for the democratic revolutions that would spread to America and then sweep through France, Europe, and eventually the entire globe in the 1800s and 1900s.

Calvin's Religion

A French Calvinist (AKA Huguenot) church. Notice the more open arrangement, including the lack of altar rails which Protestants saw as separating the clergy and congregation.

Throughout his life, Calvin maintained a staggering workload: pasturing individuals, preaching daily, massive correspondence, training missionaries, and writing commentaries on almost every book of Bible...all this while suffering from migraines. In 1538 he was even driven out of Geneva for three years before coming back to complete his transformation of the city. To accomplish this, he had three “libertines”: executed. It still took him until 1555 to establish total control.

This is one of the main biblical passages supporting the doctrine of predestination: *“God the Father hath chosen us in Him before the foundation of the world, that we should be holy and without blame before him in love; having predestinated us unto the adoption of children by Jesus Christ to Himself, according to the good pleasure of his will.”*-Ephesians 1:3-7

Calvin's view of human nature and our ability to work for our own salvation was anything but positive: *“The mind of man is so completely alienated from the righteousness of God that it conceives, desires, & undertakes everything that is impious, perverse, base, impure, & flagitious. His heart is so thoroughly infected by the poison of sin that it cannot produce anything but what is*

corrupt, & if at anytime men do anything apparently good, yet the mind always remained involved in hypocrisy & deceit, & the heart enslaved by its inward perversity.”--John Calvin

Calvin considered it the greatest blessing to have never been born and the second greatest blessing to die immediately. By the same token, he thought we should take pleasure in this world and God's creation, within reasonable limits, of course. As Calvin put it: *“There is not one blade of grass, there is no color in this world that is not intended to make us rejoice.”*

Surprisingly Calvin spent little time describing Hell, either because there was enough such talk already or life on earth was already Hellish enough, and spent more time describing Heaven

Several biblical passages are used to support the Catholic doctrine of free will:

“He isn't really being slow about his promised return, even though it sometimes seems that way. But he is waiting for the good reason that he is not willing that any should perish, & he is giving more time for sinners to repent.”--2 Peter 3:9

“...for he longs for all to be saved & understand the truth.”--1 Timothy 2:4

“If anyone chooses to do God's will”---John 7:17

Literally from the Greek: *“If it be any man's will to do His will.”*

Later Calvinists, now known as Presbyterians, revised the more fatalistic interpretation of predestination where God predestined some to be damned (a doctrine known as “double predestination” or “reprobation”) to one where sinners are responsible for their own sinful acts, but are unable to turn away from them without God's grace, which transforms human will so it can freely obey God's will. This affirms God's absolute power without rejecting human free will.

Life and Death in The City of the Saints Behavior in church. To put the rules against laughing and loud noises in church into context, one has to understand how Catholics often

behaved. Since the Catholic service was in Latin, which most people didn't understand, worship for many involved going through the motions by rote. This left time for visiting, carrying on business deals, and even telling jokes. After all, the Church was the central focus of social life, so everything blended together. For Protestants, who worshipped in the vernacular that everyone could understand, the service commanded and demanded more attention, forbidding any unseemly noises, especially laughing. For those who didn't understand that, Calvin had specific rules to remind them and punishments (fines, public humiliation in the stocks or prison) to further remind them.

Contradicting Calvin's teaching or saying he wasn't a good teacher brought a prison sentence. When one Calvinist, Pierre Ameaux, criticized Calvin at a private dinner party, he had to appear before the Council of Two Hundred, which ordered him to kneel before Calvin and ask his mercy. Calvin said this wasn't good enough and had Ameaux walk all around the city dressed only in his shirt, falling three times on his knees and begging for mercy. As a reminder of his fate if he didn't comply, a gallows was erected in front of his house. Another form of public humiliation was forcing someone to wear a giant scarlet letter A (for adultery). Of course, women suffered this more since any pregnancies out of wedlock would serve as evidence of their actions.

Dancing, drinking, and card playing brought a prison sentence. Jewelers making silver chalices and barbers tonsuring (shaving the top of the head to simulate Christ's crown of thorns) clergy passing through town could be hanged. Saying "rest in peace" over one's grave was considered blasphemy. Two young children

were beaten with rods for eating two servings of cake after leaving Church.

Cultural Reference. Not surprisingly, many considered Calvin's regime a harsh dictatorship and either resisted it or fled town. Arthur Miller's play, *The Crucible*, which on the surface about the Salem Witch Trials in Calvinist New England, was written as a veiled protest against McCarthyism in the early 1950s.

85C. THE REFORMATION'S IMPACT ON POLITICAL & ECONOMIC IDEAS

Few things in history take more devious twists and turns from their origins than ideas, and few ideas have taken more devious twists and turns from their origins than how those of the Protestant Reformation helped lead to such things as the triumph of capitalism, democracy, and women's rights. In fact, to fully understand this progression of ideas, we need to go back to the Italian Renaissance and the four major ideas that came from it:

Secularism: the belief this world and life are worth studying and living for now, not just as a preparation for the afterlife;

Humanism: the belief that humans are not helpless pawns in the divine plan, but capable of their own great accomplishments;

Individualism: the belief that individuals alone, not just groups of people, can accomplish great things on their own; and

Skepticism: the belief we should challenge accepted authorities' views rather than blindly accept them.

When these ideas made their way out of Italy and combined with the more religious attitudes of the Northern Renaissance, they helped lead to the Protestant Reformation. Two of Luther's ideas would have dramatic and unforeseen effects: the beliefs that God sees all useful jobs as equal and all believers as equal.

While Luther also believed in pre-destination, it was Calvin who especially emphasized it. That combined with the idea that all useful jobs are equal led to the conclusion that if one is a merchant, it is because he was predestined to be a merchant. Therefore, it was God's will that he work hard to earn profits for the good of the church and community. However, as religious fervor cooled over succeeding generations, Calvinist merchants started keeping more and more of their profits for themselves. Eventually, some merchants would lose all their religious fervor, leaving only a fervor for hard-earned profits, which we still refer to as the Protestant work ethic, and the triumph of capitalism in Northwestern Europe.

The idea that God sees all believers as spiritually equal also had surprising repercussions through the

succeeding centuries. For one thing, the idea of spiritual equality was seen as applying to women as well as men, but not in the political or social sense.... at first. A major, though little noted, turning point came in the 1600s with a Protestant sect known as the Quakers. They figured that, if women were spiritually equal, they should have the right to preach. However, the church was the center of their social life as well, and women assumed a more prominent place in Quaker society overall. Fast forward two centuries to 1848 and the Seneca Falls Conference, which was the start of the women's suffrage movement in America. Of the five women leading that conference, three were Quakers who would take the lead in gaining women the vote.

The spiritual equality of all believers also had profound political effects in another way. The reasoning was that, if all believers and the jobs they do are equal, that would discredit the quasi-religious status of rulers and the doctrine known as the Divine Right of Kings. Calvin said that if people were religiously repressed and kept from worshiping God in the proper manner, they had the right to resist, but only non-violently through civil disobedience. It didn't take long for a Calvinist leader in Scotland, John Knox, to extend this to justifying revolution on religious grounds. The problem was that religion and politics were so intertwined that a religious revolution had major political implications as well. This mixture of religious and political issues played out in nearly a century of religious wars that raged across the Netherlands, France, Germany, and England.

The English Revolution (1603-88) also saw economics mixed in with religious and political issues. In 1694, the rise of a capitalist middle class and triumph of democratic principles (in a very limited form) led to a remarkable book by John Locke, *Two Treatises on Government*, which summarized what that revolution had been about. Locke saw government, in typically capitalist fashion, as an implied contract between the ruler and subjects where each had mutual rights and obligations, as opposed to everything existing for the benefit of the ruler. The people owed their ruler obedience, but he was obligated to protect three things: their lives, liberties, and property. If the ruler failed to live up to these terms, the contract was null and void, justifying revolution on purely

political grounds. Thus, less than two centuries after the start of Luther's reformation, his purely religious ideas about the equality of believers and their jobs had transformed into ideas justifying political revolution on purely secular grounds.

In 1776 the American Declaration of Independence would merely restate Locke's ideas, substituting "pursuit of happiness" for property. The "Declaration of Rights of Man and Citizen" in 1789 during the French Revolution wouldn't even diverge that far and would inspire revolutions across Europe and the globe over the next two hundred years.

THE CATHOLIC REFORMATION (1540-63)

One must remember that the Protestant reformation had only limited success. The two most powerful monarchies in Europe, Spain and France, remained Catholic, as did Austria, Italy, Portugal, Hungary, Poland and parts of Germany. Still, Protestant success had been rapid and posed a serious threat to the Catholic Church. As a result, the Church went through its own Catholic Reformation, also known as the Counter Reformation, in which it reformed itself, defined its theology, reestablished the pope's authority in the now reduced Church, and prepared for a counter-offensive against the Protestants.

Early reactions by the Church to Protestantism.

The Church had often been challenged with criticism in the past, but each time had patched things up with internal reforms. Therefore, at first it failed to recognize the deep philosophical and religious issues at stake and saw Protestantism as just another protest that a few reforms could mend. Since many Church abuses were the result of the financial problems deeply rooted in the later middle ages, maybe it was too much to expect reforms of abuses at this time. However, those problems only got worse in the 1500s. Inflation, loss of lands and revenue to the Protestants, and invasions of Papal lands left Pope Paul III with only 40% of the revenues his predecessor had just ten years earlier. As difficult as it would be, the threat of further losses to the Protestants made reforms all the more necessary. In 1536, Pope Paul III established a fact-finding commission to find out why there was so much protest and what could be done about it. The resulting report, *Advice on the Reform of the Church*, blamed the Church for many of its problems and called for reforms that would convince the Protestants to rejoin the Church. Two things resulted from this report. First, the Church failed to accept responsibility for its problems, making what few reforms that resulted only half-hearted. Consequently, Protestantism kept expanding.

The second result was that the Church, rather than trying to reform itself, decided to attack its enemies. In 1542, the pope brought the Inquisition into Italy, giving the inquisitor general authority over all Italians. This effectively uprooted any elements of Protestantism in Italy and restored the pope's

authority over the whole peninsula. To a large extent, the Inquisition helped put an end to the Italian Renaissance, since it suppressed Italy's vigorous intellectual life for the sake of conformity to the Church. Remarkable individuals, such as Galileo, might still come along, but they would face the Inquisition's repression for any new ideas they might propose. The Church was also waking up to the dangers that a free press presented to the established order. In 1543, the Inquisition published the first Index of Prohibited Books, the first full-scale effort to limit or destroy the free expression of ideas through the press. It would not be the last. Among its victims was the report *Advice on the Reform of the Church*, since it was seen as giving solace to the Protestants and their ideas.

To be fair to the Church, it was caught in what seemed to be a no-win dilemma. If it reformed itself, it would lose money in the short run, but keeps more in long run. If it didn't reform itself, it would save money in the short run but lose more in the long run. Of course, making this so difficult was the fact that it had immediate expenses to pay for on a day-to-day basis.

However, by the mid-1540s, it was becoming increasingly apparent that the Catholic Church would have to institute serious reforms if it were to halt the rising tide of Protestantism. These reforms came from two directions: the Papacy at the top and the grassroots (popular) level below.

Reform from the top: the Council of Trent (1543-63).

Pope Paul III'S *Dream of calling the Council of Trent*

One problem facing the Church was the wide variety of interpretations people had of the Bible and other Church writings. This was not a new problem, but it became an urgent one when faced

with competing Protestant interpretations. Consequently, Pope Paul III called a general Church council that met at Trent, Italy to define decisively what the official doctrines of the Church were. People remembered the threat to the pope's power that councils had posed during the Great Schism a century earlier. Naturally, the pope was nervous about this and tried to restrict the council to working on Church doctrine instead of reforms that might threaten his position.

The Council of Trent met in three sessions from 1543 to 1563. Popular hopes focused on the desire to restore Christian unity, since Protestant representatives were supposed to attend (but never did). Even if it did not achieve such unity the Council did revitalize the Catholic Church and restore the pope's power within the Church. It strictly defined religious doctrine. It emphasized the role of both faith *and* good works in achieving salvation. It declared the Latin Vulgate Bible the only acceptable form of scripture, thus excluding any vernacular translations. It also reaffirmed the validity of all seven Catholic sacraments and the writings of such Church Fathers as St. Augustine as sources of religious truth. It kept the elaborate ritual and decoration of the Church, since they were inspirational for the mass of illiterate Catholics with little or no understanding of Church dogma. It also enacted various reforms, ensuring clergy were better educated and their morals better supervised. The pope was even able to restore his authority over local church and clergy at the kings' expense.

An example of the elaborate decorations and passionate art (*The Trinity* by El Greco) that the Council of Trent sanctioned in order to impress and inspire the laity

Although the Council of Trent did not peacefully restore Christian unity, it did reestablish the authority of the popes within the Catholic Church,

giving it the power to launch an offensive against the Protestants to reclaim formerly Catholic lands. Also restoring the Church's spirit was a new religious order: the Society of Jesus, commonly known as the Jesuits.

Reform from below: Ignatius Loyola and the Jesuits. The Jesuits' founder, Ignatius Loyola, (1491-1556) was quite similar to Luther in how he achieved inner religious peace, although the two men arrived at some very different conclusions about their respective faiths. Loyola was born a Spanish noble and, like Luther, had no initial plans for a religious career, being a soldier by profession. Also, like Luther, a somewhat dramatic event turned his life to religion. Instead of lightning, it was a leg broken by a cannonball while defending a fort that forced him into a long period of convalescence and ultimate conversion. Instead of the tales of war and chivalry that Loyola liked, the only reading material available was religious in nature. Eventually, this literature had its effect. Loyola experienced an intense conversion and decided to devote his life to Christ.

Like Luther, Loyola nearly died from trying to purge his guilt. He finally obtained some inner peace by deciding the Devil was responsible for any self-doubts and despair one had for sins he had already confessed to the Church and done penance for. Loyola developed a four-week long set of spiritual exercises to help others achieve similar inner peace. People would first contemplate their sins and their eternal consequences in Hell for two weeks, then contemplate Christ's life, sacrifice on the Cross, and resurrection for a week, and finally contemplate the final ascension into Heaven.

After a pilgrimage to Palestine, Ignatius decided to get an education in order to preach more effectively. In school he gathered a loyal core of followers, the most famous being Francis Xavier. In 1536, they went to Rome determined to win souls, not by the Inquisition or the sword, but by educating people, especially the young who are most impressionable.

In 1540, they founded the Society of Jesus, also known as the Jesuits. The order was organized along military lines with four ranks or classes. Members were expected to show absolute obedience to their superiors, the pope and God. Instead of ascetic activities such as endless praying

and whipping themselves, the Jesuits performed Loyola's Spiritual Exercises and menial labor. Discipline was rigorous, but flexible, helping the Jesuits produce some remarkable leaders. The Jesuits also carefully selected their target audience from two main groups in society: nobles and children. As the confessors for royalty and nobles, they exercised considerable influence on religious policies within catholic states. They also ran numerous schools, believing that if they could influence children at an early age, they would remain loyal Catholics for the rest of their lives.

The order grew rapidly and became the virtual "shock troops" of the Catholic Church. They had missionary activities to South America (still mostly Catholic) and Asia. Within Europe, they spearheaded the Catholic reformation by strengthening the Church's power in areas it still held while restoring allegiance in such areas such as Bohemia and parts of Germany.

With their Church on much firmer ground than before, many Catholics felt ready to go on the offensive against Protestantism. What resulted was a series of religious wars that would engulf Western and Central Europe for the next century.

The Council of Trent's Rough History

The Council of Trent had a rough time just getting started and staying in session. For one thing, there was the issue of where to meet. The pope naturally wanted to meet in Italy. However, the emperor, Charles V wanted it to meet inside the Holy Roman Empire where he would have more influence on its proceedings. Finally, they decided to meet at Trent, which was both in Italy and inside the Empire.

Then, as the Council was about to start, the Schmalkaldic War (1542-5) between the Lutheran princes and Charles V broke out in Germany, creating a delay of three years. Another problem was the expectation that Protestants would show up at the Council in the hope that the Church could still be unified, but no Protestants came.

In 1548, just as the Council was getting started again, a typhus epidemic broke out in Trent, so the Council moved to Bologna. However, Bologna was not part of the Empire, and the imperial representatives refused to move. Therefore, everyone else came back to Trent. Unfortunately, the members of the Council had to flee again in 1552 upon the approach of Protestant troops.

Somehow, in the midst of all these interruptions, the Council got a lot of work done. Among the issues addressed was the one that had started the Reformation: indulgences. Although the concept of indulgences was upheld in a modified manner, they were no longer to be sold after 1567.

Confessional booths. One innovation that came out of the Catholic Reformation was the private confessional booth where the sins one confessed were just between a person and a priest. This transformed confession and penance from a public humiliation to a private reconciliation with God.

Ignatius Loyola and the Jesuits

Loyola's full name when born was Inigo Lopez de Onaz y Loyola. He took the name Ignatius when he entered the Sorbonne in 1543. Among Basques, the eldest son was expected to become

a sailor. All other sons of Basque nobles, including Ignatius, who was the youngest of thirteen children, were expected to go into the military.

Surgery in the 1500s. The cannonball that hit Loyola while defending the fortress of Pamplona smashed his right leg and required setting. Unfortunately, surgeons set his leg wrong and it had to be re-broken and reset nine months later. That didn't work either, as some sort of growth started protruding from the wound, which had to be sawed off. Since his right leg was now shorter than his left leg, doctors attached a system of weights and pulleys to stretch back to its former length. Keep in mind, this was all done without anesthetics. And to think, Loyola was getting some of the *better* medical care of the day.

Loyola's ordeal. After his leg healed (more or less) Loyola made a pilgrimage to Barcelona to find the Holy Grail. He stopped at a cave outside the town of Manresa where he lived for a while as an ascetic, praying for hours at a time, nearly starving himself by only eating herbs, and scourging himself three times a day. Because of his poor diet and hygiene, his hair fell out and he nearly died. A pious local woman nursed him back to health, but he went back to scourging himself and nearly committed suicide in despair over his sins until he had a series of visions and came to the life-saving conclusion that it was Satan who was making him doubt the value of the Church's sacraments.

A detailed look at Loyola's spiritual exercises:
WEEKS 1 & 2: We contemplate our sins and the punishment they deserve. Lucifer was condemned for one sin, and isn't each of our sins a similar rebellion against God? Therefore, kneeling down, we try to picture Hell as vividly as possible; its undying fires, the torments of the damned, their shrieks of pain and cries of despair, the smell of burning sulphur and flesh and the feel of flames. From that we ask how we can escape such torments, and the only answer is through Christ's sacrifice on the cross.

WEEK 3: We contemplate Christ's life in every detail, accompanying him through every step of his life and execution: the scourging, the nails, every moment on the cross. We even lie with him in the tomb.

WEEK 4: We picture ourselves rising from the grave with Christ and into Heaven, then focusing on that blessed vision.

Some people, when taught Loyola's Spiritual Exercises, overdid it and suffered some fits and trances, which got Loyola hauled up before the Inquisition two different times. After some examination and questioning, the Inquisition decided there was nothing theologically wrong with Loyola's exercises, but cautioned him to go a bit easier on them.

The Superior General was the leader of the Jesuits and second in authority only to the pope. He was popularly called the Black Pope in reference to the black robe, which was the distinctive garb of the order.

The admonitor was one of the Jesuits' more interesting positions, especially when considered in light of the Order's strict hierarchy. As second in command, it was the admonitor's job to serve as the Superior General's conscience, warning and criticizing him when he seemed to be getting off track. The word and custom came from the ancient Romans who would put an admonitor in the chariot with a general celebrating a triumphal parade to constantly whisper in his ear the words: "Remember, you're only human."

St. Loyola and St. Francis Xavier, Loyola's most renowned missionary in Asia (below) were both canonized as saints in 1622, and their body parts were highly prized as relics. In addition, water blessed by Xavier was said to cure various illnesses and poor eyesight, while water blessed by Loyola could stop caterpillar infestations. In addition, a portrait of Xavier could supposedly protect cows from Satan.

87. THE AGE OF RELIGIOUS WARS (c.1560- c.1600)

"Kill them all; God will know his own."

--Catholic general ordering a massacre of a town containing both Cathar heretics and Catholics

By the mid 1500's, three main factors were converging to push Western Europe into a century of brutal religious wars. Two of these were the Protestant and Catholic Reformations that were firmly opposed to each other. Added to this was a prevailing medieval mentality linking religion with political issues, making it impossible for either side to tolerate the other side's presence or rule. The first round started in Germany.

Germany (1521-55). The emperor Charles V's dramatic confrontation with Luther at Worms in 1521 had resulted in outlawing the Lutheran heresy. However, this was easier said than done for several reasons. First, Charles had little control over the Holy Roman Empire (Germany), a patchwork of over 300 principalities, Church states, and free cities, all jealously guarding their liberties against any attempts by the emperor to increase his authority over them. Charles could not even get effective support from the Catholic states to help suppress the Lutherans, since his success might give him more power over Catholic princes as well.

Second, the size of Charles' empire made him many enemies, in particular France and the Ottoman Turks, who posed a constant threat from west and east. As a result, Charles felt forced to let the Protestants alone and turn to more pressing matters on his borders. Finally, Charles was plagued with money problems. Several times in his career he found himself short of funds while on the verge of a major victory. In an age of mercenary armies prone to run out on their employers as soon as funds for paying them ran out, this was fatal and forced him to let his enemies, especially France, off the hook. All these factors kept Charles from effectively dealing with the Lutherans for over twenty years.

Therefore, it was 1546 before Charles could attack a defensive alliance of Lutheran princes known as the Schmalkaldic League. Charles won a decisive military victory. But the complex forces discussed above kept him from imposing either firm imperial control or his Catholic faith on Germany. Both

Lutheranism and the privileges of the German princes were too deeply entrenched for that. Consequently, Charles agreed to the Peace of Augsburg in 1555, a compromise giving each German prince the right to choose his realm's religion, as long as it was either Catholic or Lutheran. Calvinists, Anabaptists, and other non-Lutheran Protestants were outlawed.

The Old Schmalkaldic Double-Cross

In the Schmalkaldic War between the Protestant princes and Charles V, Maurice, a minor duke and cousin of the Protestant leader, John Frederick of Saxony, betrayed the Protestant cause by invading Saxony just as the Protestants were about to meet Charles V in battle. This diversion drew John Frederick back to Saxony, thus dividing the Protestant forces and allowing Charles to win an easy and decisive military victory.

Charles rewarded Maurice with John Frederick's lands and titles for betraying his cousin. But Maurice then betrayed Charles V by joining Henry II of France against him. It was this French action that forced Charles to grant the compromise peace of Augsburg in 1555.

Instead of settling Germany's religious problems, the Peace of Augsburg actually made them worse in three ways. For one thing, Calvinism kept spreading across Germany, even among German princes, thus raising religious tensions even more. Also, Charles V, worn out by over 30 years of trying to maintain his empire and religious unity, gave up his throne. The family lands in Austria and the Imperial title went to his brother Ferdinand, while Charles' son, the staunchly Catholic Philip II, inherited Spain, the Netherlands, most of Italy, and Spain's American colonies. Philip's passionate hatred of the Protestants would also aggravate the growing religious conflict brewing. Finally, the Peace of Augsburg led to thousands of refugees, especially Calvinists and Anabaptists, fleeing Germany and spreading their religious beliefs to the Spanish Netherlands (modern Belgium and Holland), France, and eventually England.

As a result, religious conflict spread to these three countries after 1560. In the Spanish Netherlands the influx of Protestants created growing religious unrest that led to a pattern of Spanish repression,

riots and protests in response, more repression, and so on. Despite its disunity, the ensuing revolt would hang on due to its control of seaports in the North, good leadership, and anger against Spanish atrocities. In France, rising tensions between Calvinists and Catholics triggered its own vicious cycle of weakening the government, which allowed more anarchy, further weakening the government, etc. Coming from this was a series of bitter civil wars aggravated by the weak government, feudal separatism, nobles' rivalries, and foreign intervention, especially by Spain. Finally, tensions between Protestant England and Catholic Spain led the English to raid Spanish shipping and support the revolt in the Spanish Netherlands while Philip II conspired to dethrone Elizabeth I.

The critical turning event in all three of these conflicts was the defeat of Philip II's Spanish Armada (1588) that was aimed against the Dutch and French Calvinists as well as England. While this did not destroy Spain as a power, it did save Protestantism in Western Europe, thus setting the stage for the Thirty Years War. It also helped the Dutch win their freedom (1648) and become the premier naval and trading power in the 1600's. Finally, it allowed the Calvinist leader, Henry of Navarre, to take the throne of France after placating his Catholic subjects by converting to Catholicism while ensuring religious freedom to the French Calvinists. This ended the French Wars of Religion so Henry IV could lay the foundations for the absolute monarchy of Louis XIV.

Revolt of the Spanish Netherlands (1566-1648).

The Spanish Netherlands was a collection of seventeen semi-independent provinces lumped together under Spanish rule. With the possible

exception of Italy, they were the wealthiest trading and manufacturing area in Europe in the 1500's. Their main port, Antwerp, handled a full 50% of Europe's trade with the outside world. Charles V had been born there and was somewhat popular with the inhabitants. That was not the case with Philip II. It was said that Charles neglected the Spanish Netherlands, but his son, Philip, abused them. This was largely true, although Charles also heavily taxed the Netherlands for his wars and tried to impose his religious policies on them. The major difference was that Philip did it with a heavier hand and with little or no concern for the feelings of his subjects there.

Philip was Spanish born and never left his homeland after his coronation in 1556. His view of the world was very Spanish and very Catholic. He taxed the Netherlands to pay for Spanish wars and he claimed he would rather die a hundred deaths than rule over heretics. As it was, Anabaptist and Calvinist "heretics" were making their way into the Netherlands, especially after the Peace of Augsburg outlawed them in Germany. Philip, determined to get them out, brought in the Inquisition and increased the number of bishops the Netherlands had to support from four to sixteen. This repression started a cycle that led to protests and riots, more Spanish repression and so on until rebellion broke out. This rebellion would drag on until 1648, become part of the wider European struggle known as the Thirty Years War, and itself become known as the Eighty Years War.

In 1566, the Duke of Alva with an army of 10,000 Spanish troops established the so-called "Council of Blood" which burned Calvinist churches, executed their leaders, and raised taxes to levels ruinous for trade, and nearly extinguished the revolt. However, despite the disunity of the revolt itself, it managed to survive for several reasons. First, Calvinist raiders, known as "Sea Beggars", managed to gain control of some ports in the North. When word of these Calvinist havens spread, more Calvinists flocked in. As a result of this migration, Holland in the north became and remains primarily Protestant today. The second reason was the rebels' leader, William, Prince of Orange, called "the Silent" for his ability to mask his intentions. Although a mediocre general, William was a brave and patriotic leader whose selfless determination gave the revolt what little cohesion it had. His accomplishment,

much like that of George Washington in the American Revolution, would be as much to keep the rebels together as keeping the enemy at bay.

Finally, Spanish attempts to crush the revolt of the Sea Beggars often alienated more people and made them go over to the rebels' side. This was especially the case in 1576 when Spanish troops in the loyal provinces to the south rioted and went on a rampage of looting and slaughter in Antwerp after going unpaid for 22 months. (However, they were pious enough to fall to their knees and pray to the Virgin Mary to bless this atrocity.)

Fighting in the war itself was desperate and destructive. The siege of Maastricht in 1579 involved vicious battles in the miles of underground mines and countermines dug around the city. When Spanish troops finally poured in through a breach in the wall, a slaughter ensued which killed all but 400 people out of a population of 30,000. At times the rebels had to stop Spanish invasions by opening up their dikes and literally flooding the enemy (and their own crops) out. At the siege of Leyden, this was done also to provide water on which the Dutch rebels could float relief ships full of grain right up to the walls of the city. The city held out, but only half of its inhabitants survived the rigors of the siege, having subsisted on boiled leaves and roots, wheat chaff, dog meat, and dried fish skins. Interestingly enough, it was not until 1581 that the Dutch rebels formally deposed Philip II as their king and declared the Dutch Republic in the Oath of Abjuration, a document that would strongly influence the American Declaration of Independence and later democratic movements.

Philip's efforts to establish Catholic rule in England and France got the Netherlands involved in the wider scope of European religious wars. Troops from England helped the rebels, as did the defeat of the Spanish Armada in 1588, which was aimed against the Dutch and French Calvinists as well as England. After Dutch advances in the 1590's and early 1600's, the two sides signed a twelve years truce in 1609. However, the Dutch continued to blockade the Scheldt River and cut off Antwerp's trade. Gradually, this trade shifted to the Dutch city of Amsterdam, thus making it the new commercial capital of Europe. Hostilities resumed in 1621 as part of the wider conflict known as the Thirty Years War. Gradually, growing Dutch economic power

and Spanish exhaustion from constant warfare turned the tables in favor of the Dutch. In 1628, the Dutch captured the entire Spanish treasure fleet. In 1639, they crushed another Spanish Armada at the Battle of the Downs and ended Spanish naval power once and for all.

After eighty years of struggle, Spain finally recognized Dutch independence in 1648 in the Treaty of Munster. At this point, the Dutch were at the height of their commercial and naval power, although England would challenge them for that position in the later 1600's. The southern provinces would remain under Spanish, then Austrian, and finally Dutch rule until they won their freedom in 1831 and established the modern nation of Catholic Belgium in the south.

The French Wars of Religion (1562-98).

France was another country that saw the devastating effects of religious wars in the last half of the 1500's. In this case, the antagonists were the Catholic majority of France and a strong minority of French Calvinists known as *Huguenots*. Although only comprising about 10% of France's population, the Huguenots had several factors that helped them maintain their struggle for over thirty years. Their number included many nobles who provided excellent leadership. They were concentrated largely in fortified cities in the south. Finally, they were enthusiastic and well organized into local congregations.

For thirty years Catholic and Huguenot armies marched across France destroying its fields and homes. All this bred a cycle of chaos and destruction where growing anarchy would steadily weaken the French government's power, thus allowing even more anarchy and so on. There were actually seven French religious wars with intermittent periods of peace, which made these wars & this period of French history confused, chaotic, and bloody.

Once the wars started, they tended to drag on and were aggravated by several factors that made them especially destructive. First of all, besides the religious struggles, fighting between noble factions and revolts by old feudal provinces exposed and added to the weaknesses of the French state. Second, foreign intervention, especially by Spain, but also by other states such as England, compounded the turmoil and destruction. Finally, France was ruled by weak monarchs who let these forces tear the country apart.

The fighting was confused and often involved the massacres of women and children. From 1562-1571 there were eighteen massacres of Protestants, five massacres of Catholics, and over thirty assassinations. The most famous such event was the Saint Bartholomew's Day Massacre (8/24/1572), when the Paris Catholics suddenly burst upon local and visiting Calvinists and killed some 3000 of them. A letter from a Spanish ambassador shows the degree of fanaticism and viciousness that infected peoples' minds and values then: "As I write they are killing them all, they are stripping them naked...sparing not even the children. Blessed be God."

Philip II added to the disorder by actively supporting the Catholics. The turning point came with the defeat of the Spanish Armada in 1588, which led to a series of assassinations. First, the king, Henry III, assassinated the Catholic leader, Henry of Guise. Then, a fanatical monk assassinated the king for what he saw as his betrayal of the Catholic cause. The man in line to succeed Henry was still another Henry, duke of Navarre, who also happened to be the Huguenot leader. The prospect of a Calvinist king did not set too well with the predominantly Catholic population of France and led to even more fighting. Despite brilliant victories against heavy odds, Henry still faced the desperate resistance of the Parisians, whose priests told them it was better for them to eat their own children than let them live under a Calvinist king. When confronted also with Spanish intervention to put a Catholic back on the throne, Henry somewhat cynically converted to Catholicism to give his Catholic opponents no more reason to attack him.

Despite Henry's obvious political motives and the fact that he guaranteed Huguenot religious freedom by the Edict of Nantes (1598), Frenchmen were

ready to accept him as king, since they were tired of constant warfare and wished only for peace. In order to ensure this, Frenchmen were willing to submit to the stronger rule of a king. This attitude helped set the stage for the rise of France as the dominant power in Europe in the later 1600's and the rule of one of its most glorious and absolute monarchs, Louis XIV, the Sun King.

Elizabethan England and the Spanish Armada.

Certainly one of the most fascinating and capable monarchs of the age was Elizabeth I of England (1558-1603). We have already seen how she skillfully defused religious tensions in England by grafting Catholic ritual and organization onto mild Protestant theology, thus keeping most people reasonably content. Good Queen Bess, as she was known, was quite popular with her people, since she kept taxes low and knew how to get what she wanted from Parliament without being too demanding about it. She also kept the people's good will by acting as one of their own, patiently sitting through any pageants or speeches given in her honor. Elizabeth and her subjects understood and loved each other quite well. Her tolerant reign was a virtual golden age for England, nurturing among other things, the genius of William Shakespeare, possibly the greatest literary figure in its history.

Being a woman, Elizabeth had to be crafty to keep her throne, avoiding at all costs a marriage that would put a husband in her place as the real power in England. As a result, she never married, although she cleverly held out the prospect of marriage to neutralize potential enemies and keep them on their best behavior.

The great test of Elizabeth's reign was the war against Spain culminating in the Spanish Armada in 1588. The causes of the war revolved mainly around religious differences between Spain and

England that caused various acts of aggression by each side against the other. Philip II still hoped fervently to re-establish Catholicism in England. Throughout the 1570's he plotted toward this end, trying to put Mary Queen of Scots, a Catholic, in Elizabeth's place. Elizabeth countered these intrigues by finally executing Mary after a long imprisonment. She also sent troops to help the Dutch rebels, while encouraging freebooting English captains, such as Sir Francis Drake, to raid Spanish shipping. Finally, Philip decided to crush the Protestants in England, Holland, and France by sending a huge armada (navy) and army northward in 1588.

Philip's plan was to send the Armada to pick up the Spanish Army of Flanders which was then fighting the Dutch, transport it to England to crush the English, and then transport it back to crush the Dutch rebels and French Huguenots. Thus the Armada presented a serious threat, not just to England, but also to the very existence of Protestantism in Europe.

On the surface, the struggle looked like an uneven one, heavily stacked in Spain's favor. However, the English had developed radical new tactics and ship designs that would revolutionize naval warfare. They built sleeker ships powered totally by sails. Instead of boarding and grappling, they relied on cannons fired from the broadside to destroy the enemy fleet. Recent research shows that the English enjoyed a decisive edge in firepower thanks to their use of shorter four wheeled carriages that made it easier to reload and fire the cannons. This contrasted with the Spanish who still used longer gun carriages adapted for land use. These had long trailers, which made it very difficult, if not impossible, to pull them inside the cramped quarters of the ship's gun deck for reloading during the heat of battle. These innovations successfully frustrated the Armada's attempts to come to grips with the English. However, the English, in turn, were unable to stop the Spanish advance up the coast for its rendezvous with the Army of Flanders.

When the Spanish pulled into the French harbor of Calais to rest, get supplies, and try to establish contact with the Army of Flanders (which through poor communications had no idea of its approach), the English struck. Launching eight fireships into the midst of the Spanish fleet, they forced the

Spanish ships out into the open and out of formation where the English could use their superior firepower and speed to destroy the Spanish ship by ship. An ensuing storm added to the damage and forced the Spanish to give up on their rendezvous with the Army of Flanders and return home by sailing all the way around the British Isles. When the Armada finally came limping back home, a full half of it had been destroyed.

The defeat of the Spanish Armada did not destroy Spain as a great power. However, it did signal the beginning of the end of Spanish dominance of Europe. In the first half of the 1600's this process would accelerate as Spain wrecked itself by trying to maintain its power in an exhaustive and devastating series of conflicts, most notably the Thirty Years War (1618-48). As a result, a new balance of power would emerge in Europe. France would replace Spain as the main superpower, while the Dutch Republic and then England, despite their small size, would become the most dynamic naval and economic powers in Europe.

Europe's mentality would also change in the 1600's. Exhausted and disgusted by the seemingly endless religious wars and disputes, many people would take a more secular (worldly) view of things, seeing religion more as a source of trouble than comfort. By the late 1600's, these views would flower in the great scientific and cultural movement known as the Enlightenment.

Enemy at the Gates: the Turkish offensive against the West (1521-29)

In 1520 a new Turkish Sultan took the throne, Suleiman I “the Magnificent, whose armies would terrorize Europe for the next 45 years while taking the Ottoman Empire to the height of its power. Suleiman’s first major blow against the Christians was the conquest of Rhodes in 1522. For five months its defenders, the Knights of St. John (formerly the crusading order, the knights Hospitaller), desperately defended

Rhodes against a huge Turkish army. When a collapsed tower (below) finally sealed the city's fate the Turks agreed to let the Knights evacuate the city in peace instead of suffering through the bloodbath of a final assault.

Suleiman also advanced overland across southeastern Europe, taking Belgrade in 1521, which opened the way into Hungary. In 1526 he met the Hungarian army at Mohacs. The heavy cavalry of the Hungarians plowed through the first two lines of the Ottoman army and were even threatening the Sultan, when they were surprised by an artillery barrage that sent them reeling back in retreat. After that, the Hungarian army fell apart, with its young king, Louis II, and most of its nobles dying on the field of Mohacs. Hungarians still visit the memorial to the fallen at Mohacs, which they view as a major national tragedy, as seen in the phrase: “more was lost at Mohács” (Több is veszett Mohácsnál) when they experience bad luck, to indicate things could be worse.

The surviving nobles elected Charles V's brother, Ferdinand, as king of Bohemia and the remnants of Hungary. While this brought Bohemia and Hungary into the Hapsburg fold, it also triggered a Turkish invasion of Austria to support a rival Transylvanian claimant to the Hungarian throne. This war climaxed at the siege of Vienna in 1529.

Unfortunately for the Turks, a cold and rainy spring made the roads impassable, killing thousands of camels and other pack animals and leaving much of the Turkish army too ill to fight. The poor roads also forced Suleiman to leave

behind his large siege guns. His remaining lighter artillery was unable to seriously damage Vienna's walls, while Austrian guns, mounted on reinforced rooftops, were able to rake the Turkish camps and decimate attacking formations. Meanwhile, the Turks had to resort to the slower strategy of undermining the city walls, which in turn gave camp diseases such as dysentery more time to ravage the Turkish ranks.

Adding to the Turks' misery was a raid from the city that destroyed two of their artillery positions. On October 5th Turkish troops poured through a breach in Vienna's walls caused by undermining, only to be repulsed by German *landscknechte* and Spanish arquebusiers defending a new improvised palisade. A wall of pikes, musket fire, grapeshot, and a network of palisades repulsed one final Turkish assault against Vienna's damaged Carinthian Gate on October 14. Casualties piled up until the Janissaries refused to go on, retreated, and struck camp. The early onset of winter turned their retreat into a disastrous rout.

In the aftermath of the retreat, the people of Vienna came out to plunder what they could from the Turkish camp. Some of them found some strange dark beans, that when boiled in water, produced a somewhat bitter tasting drink that kept one alert and stimulated.

Coffee had entered the European diet.

No Heaven for Cowards: The other religious war: Christianity vs. Islam

“Just as there is only one God in heaven, there can be only one empire on earth”—Ibrahim Pasha, chief vizier for Suleiman the Magnificent

In addition to their attempts to crush heresy in Christian Europe, Catholics were locked in an even more titanic struggle with the Ottoman Turks for command of the Mediterranean. Throughout the 1500s the Turks terrorized Christians across Europe, while their allies/vassals, the Barbary pirates along the coast of North Africa did the same for the Mediterranean.

Stoking the flames were millennial expectations in Europe and Islam (being 1500 years since the life of Christ and 1000 years since the birth of Mohammed). Thus the struggle between Ottomans and Hapsburgs had global, even cosmic implications.

The “King of Evil”. One of the most notorious of the Barbary pirates was Oruç Barbarossa (“Red beard”), a man whose reputation for cruelty spread across Europe.

• He would dump mutilated Christians on shore with the message: *‘Go and tell your*

Christian Kings: “This is the crusade you have proclaimed.”

• Christian Peasants would cross themselves at the sound of his name.

• Legend said that God had made him invulnerable to sword thrusts and a pact with the Devil made his ships invisible.

• Once, he supposedly tore out a prisoner’s throat with his teeth and ate the tongue.

• Oruç actively spread these rumors to inspire fear.

In 1518 Charles V sent an expedition of 10,000 men to N. Africa, which hunted down and killed Oruç. His brother, Hayrettin picked up the banner and became even more notorious and feared throughout the Christian world. By the late 1520s Hayrettin, also called Barbarossa, had become the Ottomans’ main vassal/ally in the Western Mediterranean having drawn 40 corsair captains to his service, taking 12% of their plunder.

Hayrettin portrayed himself as a manifestation of the will of God and the authority of Suleiman, having prescient dreams that allowed him to escape traps, take cities, and avoid storms. He described himself among Christians *“like the sun*

among the stars, at whose appearance their light vanished.”

At Hayrettin’s approach Christian ships would surrender without a struggle, the sailors jumping in the sea rather than dying the slow death of galley slaves.

His knowledge of the sea was unmatched, getting his information on enemy positions from captives and bitter Moriscos (Spanish Muslims who had been forced to convert to Christianity).

- Once or twice a year, he would sweep the Western Mediterranean, capturing ships, burning villages and kidnapping whole populations.
- In 10 years he captured 10,000 prisoners on a 200-mile stretch of Spain’s coast.
- Among the more embarrassing episodes for Europeans was when he captured a papal galley on the high seas.
- His reputation as invincible, cruel and quick-tempered was enhanced by his own propaganda to burn fear in the hearts of Christian Europe.
- He was known simply as Barbarossa as printing presses fed Europeans’ horror with stories and legends of his atrocities.
- A common song on the Spanish coast went: “Barbarossa, Barbarossa, you are the king of evil.”

In 1529, Hayrettin took Fort Penon, a Spanish fortress that loomed over Algiers in North Africa and its shipping. Unfortunately, Fort Penon and North Africa were Spain’s forgotten frontier. The troops had very low pay, supplies, and morale. If given a chance, they would desert and try to sign on for more lucrative service in the Americas. Ironically, the Western Mediterranean had the same sort of allure of plunder and adventure for Muslims as the Americas did for Europeans in the 1500s. Hayrettin’s conquest of this fort freed Algiers as a major center for piracy, much to the distress of Christians in the Western Mediterranean.

The war between Christianity and Islam was fought on an unprecedented scale as Hapsburgs

and Ottomans could marshal previously unheard of resources. For the Hapsburgs, these came from a brand new source, the Potosi silver mines of Peru. While the Ottomans could draw on a huge and rich tax base, Portuguese Ships in Persian Gulf seriously reduced their revenues from the spice trade, largely equaling out the struggle.

The two powers also played sort of diplomatic “leapfrog” game, the Hapsburgs courting Safavid Persia to the Turks’ East, while the Ottomans allied with France.

“No heaven for cowards”: The siege of Malta

The island of Malta, strategically placed midway between Sicily and North Africa, saw some of the fiercest fighting ever between Muslims and Christians when the Turks besieged it in 1565.

The defending Knights of St. John (who had been given the island after being driven from Rhodes in 1522) defended Malta with every trick in the book, including flaming hoops to catch the Turks’ robes on fire.

One of Malta’s forts, St. Elmo, was expected to fall in a week, but held out for a month, inflicting heavy casualties on the Turks until they finally killed the last defenders. Two of them were so badly wounded before the assault that they fought to the death while propped up in chairs.

After St. Elmo fell, the Turks still had to take the main forts of Senglea and Birgu. At one point, when the Turks rolled a siege tower up to the walls, the defenders bore a hole through the wall opposite the siege tower’s wheels, stuck a cannon barrel with a double charge of powder through the hole and blew off the tower’s wheel, sending it crashing down. In another assault, the Knights of St. John ran out of ammunition and drove the Turks from the walls by throwing rocks.

During an attack on the other fort, Senglea, the Turkish bombardment was supposedly so intense it could be heard in Sicily 100 miles to the north. Once the Turks made a surprise attack by boat, using Janissaries who couldn’t swim so they wouldn’t run away. Unfortunately for them, the Knights of St. John were ready with artillery fire that sank the boats and the Janissaries with them.

A Christian relief army finally arrived to drive off the Turks, already weakened by heavy casualties and disease. Only 2,000 of 9,000 defenders, survived the siege, and of those only 600 were fit for service.

But the struggle went on.

Sea of Fire at Lepanto (1571)

In 1571, a coalition consisting of Spain, Venice, Genoa, the Knights of St. John, and the pope formed to meet the Turkish naval threat. The decisive struggle took place October 7, 1571 at Lepanto off the coast of Greece.

The two fleets stretched 4 miles, totaling 140,000 men & 600 ships, comprising over 70% of all the galleys in the Mediterranean. As they approached each other, it became apparent how much they had underestimated one another. Don Juan, the Christian commander, mixed different squadrons together to prevent defection by any one fleet. He put the lightest squadrons

on left closest to the coast to keep them from running aground.

On the day of the battle in Istanbul, the sultan Selim's turban fell twice and then his horse stumbled, both being seen as bad omens. A man who rushed forward to help the sultan was hanged for touching the sultan.

In Rome, the pope was at a meeting when he suddenly ran to the window and then called off the meeting to give thanks for great victory.

Galleys of the time typically had only 3 or 5 guns concentrated in their bows. Such ships were so narrow they could not take the recoil of a full broadside of cannons without capsizing.

Therefore, they relied on firing their guns, ramming the enemy ship, and then boarding it to take it over in hand-to-hand combat.

The Turks had more ships but they were smaller and more maneuverable, while Christian ships were fewer, but bigger, having on average twice the cannons as Turkish ships. They also sawed off their mostly ornamental rams to fire lower at close range. Muskets could get off only one shot in the time it took for the fleets to close the last 100 yards.

The Venetians had refitted 6 huge fortified merchant galleys, known as galleasses, with 30 guns, many mounted on the front so the shock of their recoil could be absorbed along the entire length of the beam. The initial shock of the firepower unleashed by these ships at the start of the battle would give the Christian fleet an early advantage.

The Turks had few muskets and no protective wooden parapets, but they had many archers with a higher rate of fire. They would dip their arrows in poison and grease their decks against the more heavily shod Christians.

They were puzzled by the big round galleasses in front, thinking they only had 3 guns each, when the galleasses' artillery opened fire with devastating effect, sinking three galleys and throwing the Turkish fleet into confusion. Following that, a volley of Venetian muskets mowed down the Turks without any protecting parapets. Then the galleasses turned 90° and fired another volley, wrecking more Turkish ships.

Getting past the galleasses, the Turks, who could barely see with the wind and smoke in their faces, opened fire, but fired high. The rest of the Christian fleet (without rams) fired close and low, hitting the Turks, so that even before the fleets collided, one-third of the Turks' ships had been crippled or sunk, already filling the sea with men and debris.

"...and already the sea was wholly covered with men, yardarms, oars, casks, barrels, and various kinds of armaments—an incredible thing that only six galleasses should have caused such destruction."

On the Christian left close to shore, the Turks, familiar with these waters, navigated the shoals around the Christian flank. Therefore, the Venetian commander, Barbarigo, interposed his flagship to block them, triggering a furious fight as Turks' boarding parties tried to storm his vessel. When Barbarigo raised his visor so he could be heard, he was shot with an arrow in the eye and died. Barbarigo's nephew brought his ship up to help and he was killed. But the Venetians, burning for revenge over the previous massacre of their garrison at Famagusta on Cyprus, threw themselves furiously into the fight, feeding soldiers onto the front ships while reserve ships brought up more men.

Slowly the tide turned against the Turks. Christian slaves on one ship rose up in revolt, whirling their chains to smash the Turks. Meanwhile, one of the Venetian galleasses crept toward shore and opened fire.

As the Turkish ships drifted toward shore where they were pinned and trapped, their crews panicked and fled for the beach, causing their ships to crash into one another and men to jump overboard. Some drowned while others used their trampled bodies as a bridge to land. The Venetians, with shouts of “Famagusta!” pursued them ashore and massacred them.

In the center, the Turkish line, somewhat torn and ragged from gunfire, still surged forward. The Turks’ flagship, *Sultana*, made for the *Real* (Don Juan’s flagship). They crashed bow to bow, the *Sultana* overriding the *Real* and crushing its oarsmen, thus leaving the two ships locked in combat.

The Papal flagship under Colonna was hit, spun around and hit the *Sultana* while another galley hit its stern. Similar collisions all along the line turned the sea into a tangled mass of thrashing men and ships.

Everywhere confusion and noise: *“a mortal storm of arquebus shots and arrows, and it seemed that the sea was aflame from the flashes and continuous fires lit by fire trumpets, fire pots and other weapons. Three galleys would be pitted against four, four against six, and six against one, enemy or Christian alike, everyone fighting in the cruelest manner to take each other’s lives. And already many Turks and Christians had boarded their opponents’ galleys fighting at close quarters with short weapons, few being left alive. And death came endlessly from the two-handed swords, scimitars, iron maces, daggers, axes, swords, arrows, arquebuses, and fire weapons. And beside those killed in various ways, others escaping from the weapons would drown by throwing themselves*

into the sea, thick and red with blood.”-- Onorato Caetani

Christians stormed the *Real* and forced their way to the mast, only to be forced back by Turkish reinforcements as each side kept feeding men from ships behind them.

Both sides slipped on the greasy and bloody deck.

Even arrows fired at point blank range pierced armor.

Muslim arrows were flying so thick that the Christian ships bristled like porcupines.

The Spanish pike men, trained in close-order drill, were devastating at close range.

Then Christian slaves joined the fight against the Turks.

The fight between the *Real* and the *Sultana* raged for an hour, but Turkish firepower slowly weakened. Christian reserve ships slowly turned the tide as the galleasses came blasting back into the fray. The Turks manning a makeshift barricade repulsed the second wave of Christians storming aboard.

As Christian ships closed in for a third assault on the *Sultana*, the Turks mounted a last ditch stand as their defenses were blasted away, the Turkish admiral, Ali Pasha, fighting to the death. Finally, as the Christians hoisted their league banner on the *Sultana*’s mast, resistance collapsed in the Ottoman center.

Meanwhile on the seaward side, the Turks kept trying to outflank the outnumbered Christians, opening a gap between the Christian center and right where the Turks poured in against the right flank of the Christian center. The Christians there, already exhausted, were also outnumbered 3, 4, or 5 to 1.

The Knights of St John went down fighting against overwhelming odds.

By now, whole ships were drifting lifeless as all their soldiers, sailors, and rowers were dead.

One soldier, wounded in the eye, pulled out the arrow with his eyeball, wrapped a bandage around his head, and fought on.

Men rolling on decks in deadly combat rolled off ships and drowned together.

One Christian crew intentionally blew up their ship, taking surrounding galleys with it.

When an aide couldn't bring himself to cut off his commanding officer's mutilated hand, the officer did it himself, went to the kitchen, tied a chicken carcass onto his stump and returned to battle telling his right hand to avenge his left.

Despite such resistance, the Turks were tearing a hole in the Christian right and might have prevailed. But as the Turkish center collapsed, the Christians could turn to meet this the threat from one side while their ships from the right flank attacked from the other. Many of the remaining Muslims fought to the last, even throwing lemons and oranges, which the Christians threw back.

“The greater fury of the battle lasted for four hours and was so bloody and horrendous that the sea and the fire seemed as one, many Turkish galleys burning down to the water, and the surface of the sea, red with blood was covered with Moorish coats, turbans, quivers, arrows, bows, shields, oars, boxes, cases, and other spoils of war, and above all many human bodies, Christian as well as Turkish, some dead, some wounded, some torn apart, and some not yet resigned to their fate struggling in their death agony, their strength ebbing away with the blood flowing from their wounds in such quantity that the sea was entirely covered by it, but despite all this misery our men were not moved to pity for the enemy...although they begged for mercy they received instead arquebus shots and pike thrusts.”

—Girolamo Diedo

The survivors were appalled by the scale of death and destruction: 100 ships destroyed, 137 more captured, 40,000 Turks dead, 25,000 of them in four hours, a rate of slaughter not equaled until World War I.

“What has happened was so strange and took on so many different aspects, it's as if men were extracted from their own bodies and transported to another world.”—Girolamo Diedo

As night fell, the fleet made for a safe harbor as a storm closed in and scattered the debris of battle as if trying to erase any evidence that such a catastrophe had happened.

A year later, the Ottoman sultan had rebuilt his fleet to its previous strength. As one Ottoman official told a Westerner, Lepanto had only singed the Sultan's beard, and beards grow back. The struggle for the Mediterranean went on.

“Long Live the Beggars”: the Revolt of the Spanish Netherlands (1566-1648)

Pieter Bruegel's *Massacre of the Innocents* (1566-7) operated on two levels. On one level it showed a biblical scene, King Herod's massacre of male Jewish babies in an attempt to kill the Christ child. However, being set in the Netherlands in wintertime, it is clearly a protest against Spain's harsh rule. However, Bruegel could claim it was just a biblical scene. Besides, most paintings of historical events showed contemporary settings and styles.

The Spanish Netherlands was a collection of seventeen semi-independent provinces lumped together under Spanish rule. With the possible exception of Italy, they were the wealthiest trading and manufacturing area in Europe in the 1500's. Their main port, Antwerp, handled a full 50% of Europe's trade with the outside world. Charles V had been born there and was

somewhat popular with the inhabitants. That was not the case with Philip II. It was said that Charles neglected the Spanish Netherlands, but his son, Philip, abused them. This was largely true, although Charles also heavily taxed the Netherlands for his wars and tried to impose his religious policies on them. The major difference was that Philip did it with a heavier hand and with little or no concern for the feelings of his subjects there.

In addition to seventeen provinces, the Spanish Netherlands also had 700 different legal systems and jurisdictions dividing it. It didn't even come to the Hapsburgs all at once. Ten of the provinces came with Mary of Burgundy's marriage to the emperor Maximilian I in the late 1400s. Charles V inherited the other seven provinces in 1543.

The Spanish Netherlands provided Charles V seven times as much revenue as the American colonies (keeping in mind their silver production would peak under Charles' son, Philip). Charles taxed them accordingly. Between 1463 and the 1520s, one village's taxes rose from 9 florins to 116. Still, even with the 300,000 florins Charles collected in taxes each year, he needed over three times that amount to meet his expenses.

This was possibly the most urbanized area of Europe, one historian estimating that 40% of its people lived in towns and cities, with just as many being literate. This was the result of having the most advanced agriculture in Europe. Thanks to sophisticated crop rotation, the Dutch were able to raise livestock and put substantial amounts of meat on their tables. One farmer even had a life-size portrait done of his prize-winning cow.

In 1549, the crown prince, Philip, visited the Spanish Netherlands, noting how big the people were, including the women (and cows), how much beer they drank, and how much they gambled. He also remarked how the women had black teeth and no interest in sex. Being very aristocratic and religious, he was put off by this society of merchants.

"The Sad King"

Philip II was Spanish born and never left his homeland after his coronation in 1556. His worldview being very Spanish and Catholic, he taxed the Netherlands to pay for Spanish wars, claiming he would rather die a hundred deaths than rule over heretics. Unfortunately, untold thousands would die their own individual deaths instead.

One historian has described Philip as a file clerk on a heroic scale. Tucked away like a hermit in his palace, the Escorial, which itself was isolated in the countryside away from Madrid, he tried to rule his worldwide empire from a desk, spending 8 or 9 hours a day writing letters to his officials. He even took a portable desk with him on family outings to get work done. Later he had to employ ministers to help him as the workload kept growing.

Philip II is also known as the Sad King, because he outlived four wives and 6 of his 9 children, probably in part due to inbreeding. He was also an extremely religious man, who dressed in black and knelt before any religious processions. He had such faith in God and the righteousness of his cause that he even sent a seaborne expedition against North Africa in the winter...with disastrous results.

Along those lines, Philip had a world-class collection of 7,422 religious relics, including 12 complete bodies of saints, 144 heads, and 306 limbs. Because there wasn't enough room to display all of the relics at once, he employed an official whose job was to constantly rotate the relics so they could all be on display at least part of the time. Philip was so obsessed with his relic collection that, when he was slipping in and out of consciousness on his deathbed, the one way to rouse him was to say something about disturbing the relics.

From protest to revolt.

The two main features of Philip's rule, religious intolerance and heavy taxes for his wars, combined in the Spanish Netherlands to create the perfect conditions for revolt. Complicating this further was the influx of Anabaptist and Calvinist refugees fleeing persecution in Germany after the Peace of Augsburg in 1555.

All rivers flow down is the main point to remember about why religious refugees flooded into the Spanish Netherlands from Germany. People fleeing with all the worldly possessions they can carry are able to take much more on boats than on their backs. It's also much easier to go with the flow of the river than against it. Since Germany's rivers flow in northerly directions, many of them flowing *down* through the Spanish Netherlands (AKA the Low Countries), that's where many of those refugees ended up.

Hedge" preaching and junior iconoclasm. Since Calvinists and Anabaptists were denied their own churches, they commonly would hold open-air prayer meetings with armed guards in the countryside in what was known as hedge preaching. In August 1566 Calvinists started seizing Catholic churches and smashing icons of saints, which they saw as idolatrous. Protestant children would take ceramic statues of saints and threaten to cut off their heads if they didn't bow. When most of them failed to bow, they then beheaded them. The game didn't usually last too long.

Philip, determined to root out heresy, brought in the Inquisition and increased the number of bishops the Netherlands had to support from four to sixteen. He also brought in the Duke of Alba with an army of 10,000 Spanish troops. Among the Duke's more notorious acts, was establishing a special court known as the "Council of Blood", which carried out 12,000 trials, leading to 9,000 convictions, and 1000 executions and exiles. Supposedly, eighteen nobles were beheaded in a single day.

"Long live the Beggars." Alba was hated as much for his infamous tax, the Tenth Penny, which was ruining trade. When a delegation of Dutch leaders came to Spain petitioning Philip to lower taxes, he replied that he wouldn't deal with a bunch of beggars. The Dutch turned this around and made being beggars a sign of honor, making "Long live the Beggars" their battle cry. Dutch nobles had specially made silver and wooden beggars' bowls to advertise their opposition to Philip II's policies. Another popular motto would be *"Better the Turk than the pope"*.

Margaret of Parma, Philip II's sister and governor of the Spanish Netherlands, tried to keep the growing turmoil under control. But her efforts proved to no avail and she finally resigned in frustration over the Duke of Alba's severe repression.

Alba's harsh rule triggered a cycle that led to protests and riots, more Spanish repression, and so on until rebellion broke out. This rebellion would drag on until 1648, become part of the wider European struggle known as the Thirty Years War, and itself become known as the Eighty Years War.

The Spanish army was the best fighting force of its day, helping Alba nearly extinguish the revolt early on by driving the rebels north through a series of bitterly fought sieges. News of one defeat reached the Dutch in Emden in the form of the hats of his drowned soldiers floating downstream. By the mid 1570s, the southern provinces were largely cleared. However, Spain faced two serious logistical challenges, both based on geography.

The Spanish Road. Getting an army from Spain to the Spanish Netherlands was a long hard process. Since sailing directly there was so risky, Spanish troops had to sail to Italy, cross the Alps, and march the whole length of Germany through various territories, some friendly and some hostile, depending on the situation at that time. This route, known as the Spanish Road, would present major logistical challenges throughout the eighty-year period of the Dutch revolt.

The great bog of Europe. Once the Spanish army got to the Netherlands, they found an environment totally alien from what they were used to in Southern Europe, especially in the northern provinces of Holland and Zeeland where the revolt would be centered. Being crisscrossed by a network of rivers and canals made it very difficult for armies, in particular cavalry, to maneuver and fight pitched battles. One English traveler called the Netherlands: “...the great bog of Europe. There is not such another marsh in the world, that's flat. They are an universal quagmire... Indeed it is the buttock of the world: full of veins & blood, but no bones in it.”

Such an environment led to fortresses very different from the ones encountered in Italy. Instead of stone, which was scarce in the Netherlands, the Dutch made skillful use of combining bastions and ravelins of packed earth (which absorbed cannon balls) with surrounding water. Packed earth was a lot cheaper than stone, while water often made it impossible to undermine the walls. One drawback with water was that it froze in the cold Dutch winters, providing easy passage to the walls.

Marching into the sea. There were good reasons for the aura of Spanish invincibility in the 1500s. One example was the siege of the island of Goes in 1572. When a Spanish relief army of 3,000 men arrived to break the Dutch siege, they were unexpectedly ordered to march across the sea to the city. The reason was that Goes had once been connected by land to the mainland, but a storm had submerged the land bridge. However,

at low tide and with an experienced guide, one could cross that submerged land bridge, which was never more than five feet deep. So, against all expectations, the Spanish waded across the treacherous mud banks on a grueling six-hour march with their guns and ammunition held over their heads. Only nine men of the 3,000 were lost in this dangerous crossing. The Dutch besiegers were so overawed by this superhuman feat that they immediately abandoned the siege.

Although plagued by the various rebellious provinces' separatist tendencies, the revolt managed to survive for several reasons: geography (again), leadership, and The Duke of Alba's brutality, which alienated much of the population. In terms of geography, Calvinist raiders, known as "Sea Beggars", captured the seaport Den Briel in the North, which led to a Calvinist influx from the South. As a result, Holland in the north would be primarily Protestant while Belgium in the south remained Catholic.

Compounding Spain's problems and protecting these gains were small Dutch flyboats able to operate in shallow inland waterways and prevent Spanish troops from landing. A Dutch naval victory at Eertvelt (1573) further helped protect the Protestant North and encouraged the further growth of the Dutch navy into the 1600s when it would be the premier naval power of the first half of the century.

William the Silent.

The second reason for the Dutch rebels surviving was their leader, William, Prince of Orange, a small principality in Southern France. He was the *stadtholder* and commander in chief of

Holland, Zeeland, and Utrecht, inheriting leadership of the revolt when his brother, Louis of Nassau, was killed during an abortive attack on the city of Groningen.

Spanish fury. Besides a reputation for invincibility, the Spanish, in particular the Duke of Alba, were known for their mercilessness. When Mechelen fell after a siege and was burned and sacked, the next town, Zutphen offered only feeble resistance but met a similarly grim fate, with the town being burned to the ground and all the men killed, many of them by being tied together in pairs and thrown into the river.

Having learned of Zutphen's fate, the citizens of Naarden negotiated the surrender of their town in return for being spared. However, once inside the walls, the Spanish systematically massacred the entire population, burning the town to flush out anyone that was hiding. As Alba put it: "they had not left a mother's son alive". The reason given for such harsh treatment was that Naarden was the first town in Holland in which heresy had taken root.

"Better a drowned land than a lost land". However, rather than breaking Dutch resistance, Spanish atrocities merely stiffened it, as seen in this message from the people of Leyden: "You hear that in our town are both dogs, cattle and horses. And if we should in the end want [for] these, there hath every one of us a left arm to eat, and reserve a right arm to beat the tyrant and the rest of you which are his bloody ministers from our walls."

This spirit of resistance would set the tone for the rest of the war.

The battle of the ice castle. When a small fleet of armed Dutch vessels became trapped in the ice near Amsterdam, the Spanish moved in for the kill. In response, the Dutch built a fortress out of ice. As the Spanish approached it, bands of Dutch musketeers burst out on strange vehicles, ice skates, some made from the shinbones of horses. Skating literally in circles around the Spanish, they would pick off a number of the enemy, quickly retreat when the Spanish

attacked in strength, regroup and then return to the attack elsewhere. Hundreds of Spanish were killed in futile attempts to come to grips with these mobile skaters. By the time the battle was over, the ice, including the fort, had melted and the ships escaped.

The siege of Haarlem (1572-3) was one of the longest and fiercest sieges of the war, lasting eight months, even through the winter when sledges and skaters brought in supplies. Holes in the walls caused by the bombardment were patched up with, among other things, icons taken from the town's Catholic church, a practice that especially enraged the Catholic besiegers and contributed to escalating atrocities on both sides. When the Spanish beheaded a prisoner and fired his head into the city, the defenders fired back a whole barrel of Spanish heads in reply. Any prisoners taken on both sides were quickly hanged in full view of the enemy.

Spanish bombardment and assaults against the walls failed. Likewise, their attempts to undermine the walls were thwarted by countermines and battles beneath the earth. On the other hand, a Dutch raid under cover of fog to spike the Spanish guns also failed. In the spring when the ice melted, the Spanish seized control of the sea and gradually starved the city into submission. While most of the surviving population was spared, Alba still butchered the entire Dutch garrison and 2,000 other citizens.

The Alkmaar flood. Next in line to face the Spanish advance was Alkmaar, a town of 1,300 citizens and 800 soldiers facing a Spanish army of 16,000. Fighting here was as fierce as at Haarlem, but the defenders had one ace in the hole: flood. After getting legal consent from local farmers, the Dutch opened the sluice gates of the local dykes. The Spanish, having captured the contracts allowing this tactic, realized why their camp was gradually filling with water, and

retreated. The farmers around Alkmaar paid a heavy price for this victory, because it would take their lands a century to recover from being flooded with salt-laden seawater.

The siege of Leyden. As the Spanish closed in on the next town, Leyden, in 1573, the Duke of Alba was relieved of command for the intense resistance his policies had inspired. Although the Spanish defeated a relief army, their own troops mutinied right after the battle, not having been paid in three years. The delay this caused allowed the Dutch to resupply Leyden.

However, once resumed, it was a tightly run siege, as starvation steadily reduced the city. After seven months, people were living on boiled leaves, roots, dried fish skins, chaff from old wheat threshings, and dog meat devoured raw on spot of slaughter.

Once again, the strategy to open the dykes was adopted, not just to flood out the Spanish, but also to open the way for 200 flat-bottom barges with food to relieve the starving city. And once again, a messenger sneaked out to get legal permission from surrounding farmers to flood their fields and ruin their crops.

In fact, the Dutch had to open a series of dykes to get to Leyden, first storming one, clearing it of Spanish soldiers, break it open, and waiting for the water to reach a depth that could support the progress of the barges. At the next dyke, the process would be repeated. Slowly the Beggars advanced, dyke-by-dyke, smashing each one as they advanced.

All this time, the Spanish besieging Leyden watched helplessly as the water kept creeping toward them. Also watching and waiting through these long weeks were the starving people of Leyden who were dying in greater numbers day by day.

Then five miles from town, an east wind blew the water back. In response, the Beggars pushed and pulled barges over the mud flats while the people of Leyden waited in the agony of expectation. Suddenly, a fresh northwest wind

came up, carrying the barges the last few hundred yards while the Beggars overwhelmed the last Spanish garrison in a brisk fight. The boats pushed triumphantly up to the quays and the dripping Beggars threw loaves of bread to an emaciated population reduced from 12,500 people down to 6500.

The starving survivors of the siege desperately devoured the bread and herring being tossed to them from relief barges, some of them choking to death in their haste to eat. Still others died from the shock of the sudden introduction of food into their bodies, which were still in starvation mode.

William of Orange, to reward the city for its steadfastness, offered Leyden the choice of an annual trade fair or a University. After careful consideration, the hardnosed burghers chose a University as a more stable year-round investment. The University of Leyden continues to thrive to this day.

"The Spanish Fury". In 1575 Philip II declared bankruptcy after getting a papal dispensation pope that let him absolve all his debts "lest he be ruined by usury while combating the heretics". The following year, the Spanish troops garrisoning Antwerp, being unpaid for 22 months, mutinied and went on a rampage of looting and slaughter, known as "The Spanish Fury", to collect their pay from the unfortunate citizens they were supposed to be protecting. After piously falling to their knees and praying to the Virgin Mary to bless this atrocity, they set fire to the streets of the wealthiest quarter and tortured anyone suspected of concealing money. As matters got progressively out of control, they killed anyone: young or old, male or female, Catholic or Protestant, even priests. When it finally ended, 8,000 people lay dead.

The next year, unpaid Spanish mercenaries committed a similar atrocity, the so-called

“pacification of Ghent”, which alienated even more people, including many Catholics, in the Spanish Netherlands.

The Union of Utrecht. In 1579 the seven northern provinces in rebellion against Spain formed an alliance, The Union of Utrecht, to better coordinate their efforts. In response, the ten southern provinces that were still Catholic formed their own alliance, the Catholic Union.

The Duke of Parma. By this time, Philip had appointed Alexander Farnese, the Duke of Parma, as the new Spanish governor of the Spanish Netherlands. Parma, being much more diplomatic and tolerant than the Duke of Alba, started winning back the support of the Catholic South. At the same time, he molded the 60,000 men of the Spanish Army of Flanders into the top fighting force of its day. He then proceeded to reconquer the northern provinces.

The siege of Maastricht (1579) showed the growing desperation of the fighting. The Spanish dug miles of tunnels to undermine the walls, leading to countermines dug even by the city’s women. In the resulting battles under the earth the defenders used boiling water and fire to scald and smoke out the enemy. To repulse assaults on the walls, the Dutch tossed hoops coated with flaming pitch over the attackers’ necks to set them on fire. In addition to other setbacks, an accidental explosion killed 500 of the besiegers. Finally, a breach in the walls brought the Spanish pouring in to sack the town. Out of a population of 30,000 only 400 survived.

The Oath of Abjuration. Interestingly enough, it was not until 1581 that the Dutch rebels formally deposed Philip II as their king and declared independence as the Dutch Republic. Their reasoning was that Philip had violated his compact and duty as a ruler to deal justly with subjects and give them good government. Therefore, he forfeited any allegiance from his subjects who now had the right to oppose a corrupt and tyrannical monarch. The Oath of Abjuration would strongly influence the American Declaration of Independence and later democratic movements.

Taking the oath was a difficult act, since they were disavowing the only form of government they had known and been told was divinely ordained. In addition, each magistrate and official had to take the Oath individually, just intensifying the anguish. One man even had a heart attack or stroke and died on the spot.

Froggy went a courtin’.

Breaking from a king was so dramatic and unprecedented that the Dutch looked for a new king to replace Philip. Elizabeth I of England was too embroiled with her own realm’s religious strife and too smart to get dragged in. Finally, the Dutch settled on Francis, Duke of Anjou, and the youngest son of Henry II of France, hoping he could bring in French support against Spain. Francis is probably best remembered as the subject of the nursery rhyme, *Froggy Went a Courtin’* which is about his efforts to marry Elizabeth I of England. The term Froggy refers either to his ugly looks (from a spinal deformity and scarring from smallpox) or a frog-shaped earring he gave Elizabeth. Elizabeth, however, played a clever game of encouraging potential husbands without ever getting married. This kept other rulers on their best behavior while not giving up any power to a husband.

Unfortunately, Francis’ Catholic faith and insistence on public worship alienated him from the Dutch; so did his failure to bring the men and money as he had promised. The final straw was the so-called “French Fury”, where Philip used French troops to try to seize Antwerp, but was driven out with heavy losses by the townsmen. After that, he left the Netherlands in disgrace and returned to France, where he died soon afterward.

The first “modern” assassination. In 1584 Philip II put a price of 25,000 crowns on William the Silent's head. This inspired a young man named

Balthazar Gerard to sneak in and shoot William on his staircase. What caught William and his men off guard was the weapon Gerard used: the wheel-lock pistol.

Previously, the only weapon a potential assassin could conceal was a dagger, which was no threat even from a few feet away. However, the invention of the wheel-lock eliminated the need to keep a lit match hidden with the pistol, thus making it possible to sneak in with a weapon that could be used from a distance.

Ironically, the pistol Gerard used in the crime was bought with money William had given him because he said he was penniless.

News of William's death brought rejoicing across Catholic Europe. Catholics wanted Gerard declared a blessed (a slightly lower category than saint) and sent his head to Cologne as a religious relic. His parents collected the reward.

However, by this time, William had given the revolt a life of its own and his murder did little except create a martyr for the Dutch cause.

Giambelli's Hellburners. Meanwhile, Parma's stolid veterans kept advancing steadily, taking Bruges and Ghent, which had both joined the rebel side, and then laying siege to Antwerp. It was there that one of the most dramatic events of the revolt took place.

Parma had completed a massive engineering project to starve Antwerp into submission: a bridge closing off the Scheldt River. The bridge was so massive that, when the Spanish captured a Dutch spy, they gave him a tour of the structure and sent him back into Antwerp to inform its people of what they were up against.

Therefore, the rebels were determined to destroy Parma's bridge. They would do it with two exploding fire ships called hellburners that were built by an Italian engineer, Federico Giambelli. The two vessels, christened *Hope* and *Fortune*, were in essence huge floating volcanoes placed inside wooden hulls to disguise them as regular fire ships. Each consisted of a brick foundation on which sat a marble chamber packed with gunpowder. On top of that was a roof holding a marble cone full of rocks, cannonballs, iron hooks, millstones, ploughshares, and anything else that could serve as a lethal projectile when hurled through the air.

They launched the hellburners at dusk on April 5, 1585. The first ship, the *Fortune*, ran aground exploding harmlessly, but diverting the attention of the Spanish troops who were awestruck by its pyrotechnic display. Meanwhile, the *Hope* got through, hit the bridge dead center, and exploded with unprecedented force. The ship, much of the bridge, nearby forts, and, briefly, even the waters of the Scheldt River, just vanished with the explosion. Over 1,000 Spanish soldiers were immediately killed as well, their bodies never being found. The shock wave leveled neighboring houses and blew people off their feet. A junior officer, sensing something fishy, had hurried the Duke of Parma away from the blast zone. Yet, even at a distance, he was thrown flat on his back and knocked unconscious.

Then slabs of granite, cannonballs, stones, and other debris started raining down from the sky. Some pieces were hurled six miles from ground zero. One Spaniard was blasted from one boat and landed in another, while one young officer was thrown across the river and landed safely half a mile away.

It was the largest man-made explosion in history.

However, the Dutch were also so awestruck by their own spectacle that they delayed moving in to finish destroying the bridge and opening the way to relieve Antwerp. In the meantime, Parma, who had regained consciousness, kept his head and regrouped his men to drive off the Dutch attack when it came. They then proceeded to repair the bridge and starve Antwerp into submission four months later.

Despite the failure of their mission, *hellburner* had entered the Spanish army's vocabulary and struck fear in their hearts. As a result, Giambelli's reputation would play a major role in events a few years later.

Ill-advised price controls. One factor contributing to Antwerp's starvation was price controls. Dutch captains were willing to run the risk of being hit by Spanish shore batteries in return for the huge profits they could make smuggling grain into Antwerp. However, when the city fathers put strict price controls on the exorbitant prices being charged for grain, that took away the incentive for the Dutch to run the Spanish blockade and Antwerp continued to starve.

Dutch resurgence in the 1590s. Despite The Spanish capture of Antwerp, events elsewhere neutralized and then reversed their progress. Most notably, in 1588 the English defeated the Spanish Armada, which saved not only England, but also the Dutch and French Protestants, from a major Spanish invasion that could have turned the tide of all three conflicts. As a result, the Duke of Parma had to take his army south to support the French Catholics in their religious wars, allowing the Dutch to retake a number of Dutch fortresses and secure their borders.

Dutch military reforms. An even more important event in military history took place in 1594 when Maurice and his brother, William Louis, inspired by the classical author, Aelian, started adapting the Roman drill and countermarch to the loading and firing of muskets. The basic idea was for soldiers to fire their muskets,

countermarch between the ranks to the rear to reload while succeeding ranks stepped up, fired, and countermarched to the rear in turn, by which time the first rank had reloaded and was ready to fire.

Instituting this reform involved several things. One was equipping soldiers with standard gauge muskets and ammunition to expedite resupplying them in battle. Another crucial feature was a manual of arms (above) that broke down the loading and firing of the musket into 42 steps that everyone did together in unison upon an officer's commands. Combining this with strict discipline and constant drill-and-march created a much more efficient army. For example, while it would take 1000 men a full hour to reform ranks, this new system could reform 2000 men in one-third that time. Soldiers were so highly drilled and disciplined that they could load their guns and perform maneuvers on the battlefield with an automatic precision that was much less likely to be disrupted by the fear and chaos of battle.

Besides increasing the smooth movement of troops in battle, the cadence of the drill and march, just as with the Romans and Spartans, created a solidarity between soldiers in the ranks that made them much less prone to panicking and running. Inside every army and soldier is a mob mentality and survival instinct that wants to run in battle. The drill-and-march didn't eliminate that instinct, but it pushed it down in the psyche for long enough to make it more likely that the mob mentality in the opposing army took over first.

The countermarch required spreading out the lines to allow free movement between the ranks for movement to the rear. While this made the musketeers more vulnerable to enemy pike men and cavalry, it also started extending an army's battle line so that it threatened to outflank the enemy. However, the full conversion to extended linear tactics wouldn't take place for nearly a century when the bayonet made the pike obsolete.

Although Maurice of Nassau's reforms would herald a revolution in military tactics, his armies only fought one major battle against the Spanish, at Nieuwpoort in 1600, where the smaller more flexible tactical units and their discipline won the day. However, it would be developments elsewhere that would turn the tide in favor of the Dutch.

For one thing, Dutch sea power was making itself felt. In 1607, the Dutch defeated the Spanish at Gibraltar, opening the Mediterranean to Dutch trade and growing economic power. Meanwhile, the Dutch blockaded the Scheldt River, cutting off Antwerp's trade and diverting it to the Dutch city of Amsterdam, which would replace Antwerp as Europe's premier trading port in the 1600s. And as Dutch economic resources grew, Spain's declined accordingly, helping the Dutch war effort while hurting Spain's, further helping the Dutch economy, and so on.

Meanwhile in the 1590s, famine, followed by plague, afflicted Spain, further depleting its population and resources. Even Philip II's death in 1598 failed to convince Spain to give up. So the war dragged on into the 1600s, further weakening Spain as the Dutch won more victories. Finally the two sides agreed to a 12-year truce in 1609. However, Dutch raids on Spanish shipping continued and everyone expected war to resume when the truce expired in 1621. It did resume, but this time as part of the broader European struggle known as the Thirty Years War.

Gradually, growing Dutch economic power and Spanish exhaustion from constant warfare

turned the tables in favor of the Dutch. In 1628, a Dutch East Indies Company fleet of 31 ships captured the Spanish treasure fleet, known as the Golden Bird, off the coast of Cuba. This dealt a crippling blow to Spanish finances, while netting the Dutch some 180,000 pounds of silver, 134 pounds of pure gold, and thousands of chests of pearls and other gems, worth an estimated 15-million guilders. Some Spanish ships were so heavily laden with treasure that it blocked their gun ports. The Dutch captain, Piet Hein collected a 7000 guilders reward, but was killed by a cannon shot in a fight with pirates six months later.

The Battle of the Downs. On October 31, 1639 a Dutch fleet blockaded and then demolished a Spanish armada of 77 ships off the coast of England while Spain's English allies merely looked on. This crippled Spain's efforts in the Spanish Netherlands and effectively wrecked its naval power, opening the way for the English and Dutch to rule the seas from that point on.

The next year, the Dutch destroyed another Spanish squadron off the coast of Brazil and established a colony there. Consequently, Portugal, ruled by Spain since 1580 when Philip II inherited its throne, rebelled against Spanish rule, followed by Catalonia in Northeast Spain. Those revolts, combined with Spain's faltering efforts in the Thirty Years War, finally led to Spain agreeing to give up and grant the Dutch their independence.

After eighty years of struggle, Spain finally recognized Dutch independence in 1648 in the Treaty of Munster. At the swearing of the oath, the Spanish held their hands on Bibles, while the Dutch delegates pointed their hands toward heaven, symbolizing the religious differences that had kept them fighting for eighty years.

At this point, the Dutch were at the height of their commercial and naval power, although England would challenge them for that position in the later 1600's. The southern provinces would remain under Spanish, then Austrian (1718-1815), and finally Dutch (1815-31) rule until they won their freedom and established the modern nation of Catholic Belgium in the south.

The French Wars of Religion (1562-98)

France was another country that saw the devastating effects of religious wars in the last half of the 1500's. In this case, the antagonists were the Catholic majority of France and a strong minority of French Calvinists known as *Huguenots*.

Although only comprising about 10% of France's population, the Huguenots had several factors that helped them maintain their struggle for over thirty years. Their number included many nobles who provided excellent leadership. They were concentrated largely in fortified cities in the south. And finally, they were enthusiastic and well organized into local congregations.

The case for noise ordinances. In fact, it was largely the Huguenots' enthusiastic worshiping, in particular their loud singing, which catalyzed hostility between the two religious groups. Unlike the Catholic mass where specially trained choirs did the singing (until Vatican II in the 1960s), the entire Protestant congregation took part in singing. Contributing to this practice was one of the era's most popular types of printed literature, the Psalter, which put psalms to music for Protestant congregations to sing. However, this was no guarantee that all Protestants could sing on key, although they did tend to make up for it in spirit (and volume).

This could be a problem when Calvinist and Catholic services were held at the same time in close proximity to one another. For example, in Paris, in reaction to the Huguenots' loud and boisterous singing, Catholics across the street started ringing their church bells to drown them out. When a Huguenot entered the Catholic Church to silence the bells, he was killed, which triggered a riot where the Huguenots sacked the Cathedral and smashed its icons. By the time it was settled down, 80 people had been wounded. In another incident, a riot was sparked when a Huguenot publicly mocked Catholic rituals by baptizing his dog in a fountain.

The most infamous incident was the Massacre at Vassy in 1562, when Francis, Duke of Guise, stopped in the village of Vassay for mass, but was disturbed by loud Huguenot hymns in a nearby barn that had been converted into a church. When he asked them to defer singing for 15 minutes, they refused, which led to an exchange of "compliments", causing the Catholic nobles to draw their swords. When a rock flew out of the Huguenot crowd and hit Francis, all hell broke loose with the Catholics killing 23 and wounding 100 Huguenots, most of them burning to death when the duke set their church on fire.

Scenes like that at Vassy repeated themselves and raised war fever across France in the early 1560s as Huguenots seized fortified towns in self defense. There were eight French religious wars (or seven, depending on what one counts as a war) with intermittent periods of peace, making this one of the most confused, chaotic, and bloody periods in French history.

Once the wars started, they tended to drag on and were aggravated by several factors that made them especially destructive. First of all, besides the religious struggles, fighting between noble factions and revolts by old feudal provinces exposed and added to the weaknesses of the French state. Second, foreign intervention, especially by Spain, but also by other states such as England, compounded the turmoil and destruction. Finally, France was

ruled by weak monarchs who let these forces tear the country apart.

Henry II's death. France's weak leadership and subsequent religious wars might have been averted except for a bizarre accident that killed its strong and vital king, Henry II. Despite the premonitions and warnings from his wife, Catherine de Medici, Henry II of France took part in a joust celebrating the Peace of Cateau-Cambresis with Spain in 1559. Jousting then used flimsy lances that would break on impact instead of wounding or killing an opponent. Unfortunately, in a freak jousting mishap, the shattered lance of Henry's opponent's somehow pierced the king's eye. He lay in agony for nearly two weeks before dying after the wound went septic. Henry left three weak sons to succeed him just as religious tensions between Catholics and Calvinists threatened to boil over into open warfare.

Catherine de Medici, Henry's widow and the queen mother could control her three weak sons who reigned in quick succession, but little else. Despite the hostility of the male sources to a female ruler, she seems to have honestly tried to steer France on a middle course of religious tolerance that neither side could seem to live with.

The Battle of Dreux (1562) was the first major battle of the French Wars of Religion and served as a textbook case of incompetent leadership on both sides. An army of 8-9,000 Huguenots stumbled upon a Catholic army twice its size, but decided to fight anyway. The Huguenots, however did have better and more cavalry, including German reiters armed with wheel lock pistols instead of heavy armor and lances.

At first, the Huguenot cavalry on the right flank drove off its Catholic counterparts. But instead

of turning to attack the Catholic flank, as they should have, they looted the enemy camp, which was more fun. Meanwhile, the Huguenot commander on the left was doing his level best to wreck his troops in fruitless charges against the opposing Swiss pike men armed with eighteen-foot pikes. However, just as the Catholics were about to win, the Huguenot cavalry returned to save the day, ending the battle in a draw. To further complicate the situation, each army's commander had been captured by the enemy. When Catherine de Medici got premature word indicating a Huguenot victory, she supposedly said they should prepare to be praying in French, referring to the Huguenot custom of using the Vernacular instead of Latin.

The First Religious War ended in 1563 with the Edict of Amboise, which restricted Huguenot worship to the suburb of one town per district and the homes and estates of Huguenot nobles. However, all eight *parlements* (regional courts) refused or delayed enacting this edict until the king came personally to ask them to do it. In the meantime, in order to pressure Catherine into renewing the war, the Duke of Alba marched the Spanish army along France's northern frontier, while the Jesuits came in and started executing Huguenots.

Thus began a dreary pattern of war starting up again, the royal government being unable to suppress the Huguenots and having to make a compromise peace, which further aggravated the Catholics, in particular the Jesuits, who stirred up war fever and started the cycle all over again.

There were several reasons for the Catholics' inability to beat the Huguenots. For one thing, royal garrisons were scattered across France's borders, guarding especially against Hapsburg aggression. Therefore, it took them a long time to concentrate against the Huguenots. And even if they defeated the Huguenots in battle, they probably faced long and expensive sieges that they didn't have the funds for. Likewise, at the end of the war, they had to demobilize their armies, which would take a longer time to re-mobilize and concentrate for the next war than was true for the Huguenots concentrated in their

fortified cities. Adding to these difficulties was the Huguenot capital and seaport, La Rochelle, through which foreign aid from England and the Dutch could enter France.

The viciousness and confusion of these wars was exacerbated by massacres of women and children. From 1562-1571 there were eighteen massacres of Protestants, five massacres of Catholics, and over thirty assassinations.

The Saint Bartholomew's Day Massacre

(8/24/1572) was the most famous such event. Following concessions at the end of the Second and Third Religious Wars (1567-8; 1568-70), Catherine de Medici decided to seal the peace by marrying the Huguenot leader, Henry of Navarre to the king's sister, Marguerite of Valois. Since there were four surviving sons of Henry II, people figured at least one of them would have a son and heir, so the throne would not revert to Henry of Navarre through Marguerite. They were wrong on all four accounts.

Unfortunately, another Huguenot leader, Coligny, wanted to control royal policy and take Flanders from Spain, thus instigating war with the big power of the day. Tensions were raised further by the presence of 5,000 armed Huguenots in Paris to celebrate the wedding, which took place with Huguenot modifications and without the pope's approval. When Coligny tried to turn the king against his own mother, pressure mounted from the ultra-Catholic faction led by the Guise family to carry out a massacre of the Huguenots while they were trapped in Paris. Driving events forward was an attempted assassination of Coligny, but it remains unknown who masterminded it: the Guises, Catherine de Medici, or the Duke of

Alba. Whoever, the culprit, the Protestants angrily demanded justice, which scared the king, Charles IX, into agreeing to arm the Parisians and shut the city gates to prevent any Protestants escaping.

Signaling the start of the massacre was the ringing of the Matins bells sometime after midnight on August 24, 1572. The duke of Guise and 100 soldiers burst in and murdered Coligny and several other Huguenot leaders, while the Parisians, incensed by recent events, started hunting down any Protestants they could find crying out "Kill, Kill, The king orders it."

As typically happens with such events, matters got out of control and went far beyond what Catherine wanted, as women and children were butchered in the frenzy. It also served as a convenient excuse for some to carry out personal vendettas, as merchants murdered their competition, debtors erased their debts along with their creditors, prospective heirs murdered relatives. Even the composer Claude Goudimel and the philosopher Petrus Ramus fell victim to the slaughter. Henry of Navarre escaped being killed by quickly converting to Catholicism. He converted back to Calvinism in 1576.

A letter from a Spanish ambassador shows the degree of fanaticism and viciousness that infected peoples' minds and values then: "*As I write they are killing them all, they are stripping them naked...sparing not even the children. Blessed be God.*" A cardinal rewarded the messenger who brought news of this event with 1,000 crowns, and the pope had a special medallion struck to commemorate the massacre.

Finally, after three days the massacre was stopped. Unfortunately, a few days later a Hawthorne bush blooming out of season was hailed by a monk as a miracle, which he announced by ringing the bells, starting the massacre up again.

How many died as the massacre spread to the rest of France is anyone's guess, but most likely 2-3,000 Huguenots died in Paris with several thousand more in other towns with large minorities of Protestants. In addition, several thousand more probably fled the country.

Of course, this triggered a Fourth Religious War (1572-3), which centered on the failed siege of the Huguenot city, La Rochelle. Despite another compromise peace, recent events just led to further polarization of French society as people were increasingly disillusioned with the weak monarchy and its inability to control events. Therefore, France degenerated into even more chaos as conflicts broke out between different families and old feudal provinces tried to assert their independence.

At the same time, Calvinist writers were claiming that subjects had the right and duty to depose a king who failed to rule justly and effectively. In 1574, the anonymous author of the *Political Discourses* claimed "*the sovereign community [the people] is superior to him [the king]...The community gave [public] power to the prince...If he abuses it they can invoke the law which holds that the thing given [public power] can be revoked due to culpability of the one to whom it was rendered.*" This idea would resurface in 1581 with the Dutch Oath of Abjuration, and it wouldn't stop there.

On a different note, a group of political moderates, later known as *Politiques*, were advocating more religious tolerance to ensure the public peace. This was another idea that would gain traction as France continued to be torn apart.

Meanwhile Religious Wars Five (1575-6), Six (1576-7), and Seven (1580) accomplished nothing more than further erosion of royal power. More devastating than these were the ravages perpetrated by both sides' employed and unemployed mercenaries and the peasant revolts that broke out in reaction against them.

When Francis of Anjou, Henry III's younger brother died in 1584 after his unsuccessful sojourn as Dutch king, that put the king's brother-in-law, Henry of Navarre, once again a Calvinist, in direct line to succeed the childless king. Fear of this happening led to the resurgence of the Catholic League led by Henry of Guise who pushed through the Treaty of Nemours (1585), which revoked all the liberties the Calvinists had gained since 1562. And that led, once again to civil war.

The War of the Three Henrys (1585-98) as the Eighth Religious War is known, concerned Henry III, Henry of Navarre, and Henry Duke of Guise. Supporting the Duke of Guise and Catholic League was Philip II whose Armada in 1588 was designed, among other things, to help the French Catholics. Spurred on by this support, the Catholic League drove the king, Henry III from Paris.

In September, soon after the Armada's defeat, the king summoned a meeting of the Estates General at the Chateau de Blois where he had his henchmen murder the Duke of Guise (12/23/1588). On the floor below, Catherine de Medici lay in her deathbed where she could hear the Duke dragging his assassins across the floor as they cut him to pieces.

After the murder of the Duke of Guise, the king found himself alone and caught between hostile Huguenot forces to the south and Catholic League forces now led by Charles de Lorraine, duc de Mayenne. Therefore, he sealed an accord with the Huguenot leader, Henry of Navarre at Plessis-les-Tours (4/30/1589).

Paris now broke out in open revolt against the king, now allied with the heretic Henry of Navarre. Angered by the king's apparent defection to the Protestants, a Jacobin Friar, Clement, saying he had important letters from Paris (then under siege) for the king, assassinated Henry III with a concealed dagger (8/1/1589). Before dying the next day, Henry recognized Henry of Navarre as his heir and urged him to turn Catholic.

That left Henry of Navarre (above) as king, but there was no way the Parisians and many other French Catholics would accept a heretic as king. So the war went on.

Henry was a brilliant general who won victories against armies two or three times the size of his own. He was also an inspirational leader whose white plumed helmet could always be seen in the thick of the fighting. As a result he commanded the loyalty of Catholic as well as Protestant troops.

Eventually, Henry was able to lay siege to Paris. Conditions became so desperate that people ate horses, dogs, cats, grass, and even made flour from ground up cemetery bones. While people starved, priests told Parisians they would be better off eating their own children rather than letting them live under heretic king.

When Philip II of Spain sent the Spanish Army of Flanders into France to relieve Paris, Henry somewhat cynically converted (again) to Catholicism, supposedly saying, "Paris is worth a mass." In other words, it was worth it to convert to Catholicism to give his Catholic opponents no more reason to attack him and to secure the crown.

Despite his obvious political motives and the fact that he guaranteed Huguenots religious freedom by the Edict of Nantes (1598), the French people, tired of constant warfare, readily accepted him as king in return for peace. Therefore, his entry into Paris (above) was a virtual triumphal parade, with the dashing king waving to the ladies while the Parisians cheered him wildly. Finally, in 1598, the pope recognized Henry's conversion and granted him absolution.

Henry IV would prove to be one of France's most popular kings as he restored peace and prosperity to a land wrecked by thirty years of warfare. By the same token, the French were also willing to submit to the stronger rule of a king, which helped set the stage for the rise of France as the dominant power in Europe in the later 1600's and the rule of one of its most powerful and absolute monarchs, Louis XIV, the Sun King.

Henry was one of the few kings to care for the common people's prosperity, saying: "*If God spares me, I will ensure that there is no working man in my kingdom who does not have the means to have a chicken in the pot every Sunday!*" He also adorned Paris with the Pont Neuf over the Seine River and a 400-meter long addition to the Louvre, making it the longest building of its kind in the world then.

Henry would meet the fate of the other two Henrys: assassination. In 1610, as he was about to set out to war against the Hapsburgs, a Catholic fanatic named François Ravailac plunged a dagger into the king for his plans to fight against another Catholic king.

The Age of Elizabethan England

Elizabeth judges Venus, Juno, & Minerva, implying she set the standard for beauty & wisdom

One of the most fascinating and capable monarchs of the age was Elizabeth I of England (1558-1603). We have already seen how she skillfully defused religious tensions in England by grafting Catholic ritual and organization onto mild Protestant theology, thus keeping most people reasonably content. Unlike her sister, “Bloody Mary”, Elizabeth also avoided religious persecution, merely fining someone 5£ for not belonging to the Church of England.

Known variously as Good Queen Bess, Gloriana, and the Virgin Queen (merely for her marital status), Elizabeth was quite popular with her people, since she kept taxes low and knew how to get what she wanted from Parliament without being too demanding about it.

She also kept the people's good will by acting as one of their own, patiently sitting through any pageants or speeches given in her honor. Elizabeth and her subjects understood and loved each other quite well. Her tolerant reign was a virtual golden age for England, nurturing among other things, the genius of William Shakespeare, possibly the greatest literary figure in its history.

Each summer, Elizabeth led her court on an annual “royal progress”, a leisurely 1-2 month tour of the country that, in addition to avoiding disease-stricken London, made her visible and accessible to her subjects. Accommodating the royal court was not cheap, since it typically traveled with up to 300 wagons and carts.

In addition to being well educated and politically adept, Elizabeth was a skilled dancer and musician playing the lute and virginal (an early precursor to the piano). Even into her 40s she could dance with youthful grace and energy such Italian dances as the Lavolta, which required one to step high and lively. When not dancing she would count the cadence for other dancers with an imperious foot.

Much of Elizabeth’s appeal came from her willingness to give full attention to any entertainments her people would put on for her, such as a “wild man” covered with moss & ivy reciting a humorous poem for the queen while

returning from the hunt. For subjects overawed by her majesty’s presence, she would warmly say, “Be not afraid” to calm their nerves.

Popular entertainments for the common folk were somewhat rough and tumble, including bear baiting where spectators would bet on which dog would last longest while attacking a tethered bear.

Other popular sports were logrolling, where the goal was to break as many of an opponent’s toes as possible, and cockfighting where specially bred roosters with metal spurs and sharpened beaks would fight to the death. Even schoolboys were allowed to bring their killer birds to school each Shrove Tuesday so they could fight in the school cockpit.

Even the world’s most popular sport, soccer, has somewhat brutal roots in Elizabethan England. Each Shrove Tuesday, apprentices would engage in a no-holds-barred game with a leather-cased ball. The game had no apparent rules or restrictions except to get the ball to the other team’s end of town.

Such games typically degenerated into brawls that offered opportunities to settle old scores. As one contemporary put it: *“sometimes their necks are broken, sometimes their backs...sometimes one part thrust out of joint.”*

Local residents and merchants hated his sport, scurrying to protect their goods while shouting curses and shaking their fists (sometimes from rooftops) at the rowdies

It was said that Elizabeth, instead of getting married, had a love affair with the English people. Or, as she put it: *"Though you have had & may have many mightier and wiser princes, yet you never had nor shall have any that will love you better."*

Being a woman, Elizabeth had to be crafty to keep her throne, avoiding at all costs a marriage that would put a husband in her place as the real power in England. As a result, she never married, although she cleverly held out the

prospect of marriage to neutralize potential enemies and keep them on their best behavior.

Deadly cosmetics. In 1562 at age twenty-nine, Elizabeth contracted smallpox, which scarred her face. To cover these blemishes, she wore makeup consisting of vinegar and white lead, which is poisonous. Whether because of that or old age, she gradually lost her hair and teeth. It is quite likely that when she died at the ripe old age of seventy, it was because of blood poisoning caused by her makeup.

Mary Stuart, Queen of Scots

The great test of Elizabeth's reign was the war against Spain culminating in the Spanish Armada in 1588. The causes of the war revolved mainly around religious differences between Spain and England that caused various acts of aggression by each side against the other. Philip II still fervently hoped to re-establish Catholicism in England. Throughout the 1570's he plotted toward this end, trying to put Mary Stuart (AKA Mary Queen of Scots), a Catholic, in Elizabeth's place.

Given her turbulent childhood and position as a woman in a man's world, Elizabeth was extremely sensitive to any threats, real or perceived, to her throne. Such was the case with Mary Stuart, who, as the granddaughter of Henry VIII's sister Margaret Tudor, was Elizabeth's first cousin once removed. Mary's father, James V, had died when she was only six days old and she was crowned nine months later.

Troubles with Henry VIII who raided Scotland to pressure Mary into marrying his son Edward, led to her mother, Mary of Guise, was French, to take her to France at age five, where she married the crown prince, Francis. (To further confuse

things, the four maids-in-waiting she took to France were also named Mary). Therefore, Mary was Catholic and probably more French in spirit than Scottish. Unfortunately, soon after her new husband succeeded to the French throne as Francis II, he died and she returned to Scotland. However, being basically French and Catholic, she was poorly prepared for handling the complicated factional politics of her homeland. The radical Calvinist leader, John Knox, especially criticized her for her religion and frivolous French ways.

Being a widow, she married Henry Stuart, Lord Darnley, her half first cousin, but it was an unhappy marriage, as Darnley was jealous of Mary's friendship with her personal secretary, David Rizzio, and murdered him in the presence of his pregnant wife. Some time later Darnley's house mysteriously blew up with him in it, and soon afterwards, Mary wed the suspected murderer, James Hepburn, 4th Earl of Bothwell. As a result, the Scottish nobles imprisoned Mary and forced her to abdicate. Although she escaped, she failed to reclaim her throne and fled to her cousin, Elizabeth, in England, hoping she would help her regain her throne.

However, since Mary was next in line for the throne of England after Elizabeth (or before her, since Catholics still claimed she was illegitimate), she was imprisoned and closely watched, especially after the Ridolfi Plot in 1570, a failed attempt, probably funded by Philip II of Spain, to murder Elizabeth and replace her with Mary. Still, Elizabeth was reluctant to kill her cousin, and kept her imprisoned for 17 years. Not until 1587, as war with Spain loomed on the horizon and after 19 years of being held prisoner in England, did she finally have Mary beheaded.

Sir Francis Drake

Elizabeth more than got her revenge against Philip through the raids of Sir Francis Drake, who operated as a privateer/pirate through a long and storied career. Such privateers often operated with what were known as letters of Marque, whereby they were authorized to capture another country's vessels and bring them in for sale.

Drake had a special vendetta against the Spanish after being trapped and nearly captured by them in Mexico in 1568. After a failed raid in 1572 on the Spanish Main (the Isthmus of Panama where Peruvian treasure was carried from the Pacific to the Atlantic for transport by sea to Spain), he hit pay dirt the next year, capturing a mule-train carrying twenty tons of Peruvian gold and silver. Unfortunately, he couldn't haul it all back to his ship and had to bury part of it, possibly being the source of tales about buried pirate treasure.

Drake's wildest exploit was circumnavigation of the globe (1577-80) as a result of his raiding Spanish shipping in the Pacific. After exploring the coast of North America and claiming it for England, he crossed the Pacific, traded for spices in the Moluccas, and headed home. Out of 164 men who set out, 59 made it back. The Queen's share of the plunder was worth more than an entire year's taxes.

Drake also made a raid with 30 ships on the Spanish port of Cadiz in 1587, where the Spanish Armada was preparing for its invasion of England. The raid, with the help of some Spanish fire ships that went astray, destroyed 24 Spanish ships. Possibly of even greater significance, on his way home Drake intercepted and destroyed a Spanish convoy carrying seasoned barrel staves. The significance lay in the fact that seasoned wood has fewer microbes than green wood. Thus food and water in barrels made from green wood spoil much faster. There is no telling how much damage this did to the health of the sailors and soldiers in the Armada, but it probably had some impact.

The Spanish Armada (1588)

The great test of Elizabeth's reign was the war against Spain climaxing with the Spanish Armada in 1588. The causes of the war revolved mainly around religious differences between Spain and England that caused various acts of aggression by each side against the other. Philip II still fervently hoped to re-establish Catholicism in England. Among other things, he had plotted to put Mary Stuart (AKA Mary Queen of Scots), a Catholic, in Elizabeth's place.

Spanish preparations experienced incredible delays due to Philip's over-centralized micro-management and the incompetence of the Armada's commander, Santa Cruz, a good fighting officer, but a poor staff officer for organizing the logistics of such an expedition. Therefore, by early 1588, the Armada was falling apart, being reduced to 104 unseaworthy ships while supplies rotted and attrition from sickness, in particular a typhus epidemic that decimated its army from 12,600 men in January down to 10,000 by February.

Finally, Philip replaced Santa Cruz with the Duke of Medina Sidonia, an excellent staff officer, but with little or no combat experience at sea. Thanks to his hard work, the Armada grew back to 130 ships and 19,000 soldiers. However, the crash program caused many gunsmiths to cut corners, so their guns were not bored or cast properly, making them prone to not fire straight or, in some cases, to blow up. Also, since the guns were cast all over the Spanish Empire, there was no standard gauge for their cannonballs, making resupplying them a nightmare.

When completed, the Armada consisted of a hodgepodge of regular sailing warships (galleons, left) heavily armed with cannons along with big merchant ships packed with soldiers

and supplies, smaller Caribbean escort ships with few guns and lots of cargo space for extended voyages, and large oar driven Mediterranean galleasses (right) without continuous gun decks and that were slow and ill-suited for the rough waters of the North Atlantic.

The English fleet. On the surface, the struggle looked uneven, heavily stacked in Spain's favor. However, the English had developed radical new tactics and ship designs that would revolutionize naval warfare. It largely started with Henry VIII who by 1547 had a fleet of 53 ships armed with unprecedented numbers of cannons. Supposedly, Henry tested some new Flemish guns he had just received by leveling a peasant village, then declaring he had "cannon enough to conquer Hell".

Combined with all these guns was a revolutionary design for naval gun carriages. Up to this point, people thought of naval battles mainly as land battles fought at sea. After a preliminary bombardment, ships would grapple one another and soldiers would fight to conquer the enemy vessels. Since the guns, as in land battles, were only for preliminary firing, mainly at the enemy sails and rigging to slow them down to expedite boarding, they were seen as being good for only one or two shots before the real fighting started. Therefore, they kept the long two-wheeled trailers on the ends of their carriages, which on land were useful of hitching up to horses for moving (which would be somewhat useless on board ships). However, the narrowness of the ships' gun decks combined with the length of these carriages made it hard for gunners to pull the guns inside for reloading. But, since they were only to be used for preliminary firing anyway, it didn't seem to matter.

The English approached the use of guns differently. Since the ships' buoyancy made them mobile gun platforms, anyway, why not use them primarily for their firepower? Therefore,

they designed shorter, four-wheeled gun carriages (without the long trailers) that could be pulled in and reloaded for firing over and over again. To do this effectively required faster sailing ships that could keep their distance from the enemy to avoid being boarded while they pounded them with their guns.

His Grace a Dieu (AKA *Great Harry*) was one of the first ships to carry a large number of these guns, including some weighing two tons and able to fire a 66-pound shot 500 yards. However it kept the old ship design with high castles and grappling hooks for close combat. Its keel length, 50 meters, was only twice its width. The crew of 700 included 400 soldiers, also reflecting the older style of warfare.

The weight of all those guns combined with the ships' high center of gravity made these ships somewhat unstable. To compensate, the gun decks were placed closer to the water line. As a result, another of Henry's ships, the *Mary Rose* sank in a storm after its gun ports, only 14" above the water line, were left open. The undersea excavation of the *Mary Rose* has supplied historians with a wealth of information about life aboard sixteenth century sailing ships.

The problem of slow top-heavy sailing ships was largely solved by John Hawkins in 1578 with a new design known as "race-built", coming from the French word to shave (related to our word razor). What he shaved off were the fore and aft castles of the old style warships. These new ships (below right) had four qualities:

- 1) They were longer in relation to the beam with finer underwater lines.
- 2) Elimination of the castles reduced wind resistance.
- 3) They had more efficient sail plans.
- 4) They had more guns and they were mounted on the new gun carriages.

This required a fine balance between speed and heavy armament. While Spanish ships were built for ocean voyages to carry and protect their treasure, making them bulky and slow, the English had no need for such bulkiness.

Therefore, while English guns made up 14% of their ships' weight, guns on the bulkier Spanish ships only comprised 4% of their weight. More than compensating for the weight of their guns were the English ships' sleeker lines and more sophisticated sail plans.

The result was a ship combining phenomenal sailing performance with firepower against other ships. As John Howard of Effingham put it: "*I protest it before God... if it were not for her majesty's presence, I had rather live in the company of these noble ships than in any place.*"

Another factor favoring the English was the difference between the two countries' attitude toward naval service. The Spanish were soldiers and saw naval service as second best, if not demeaning. Consequently, their admirals were land soldiers who typically didn't understand the nuances of naval warfare and were less prone to listen to ships' captains who did grasp those nuances.

By the same token, Spanish ships had two distinct groups of men: sailors who sailed the ships and soldiers who were along for the ride until there was a battle. This made for overcrowded ships, which ate up supplies, reduced available living space per man, and didn't help sanitation any. Also, the two groups didn't like each other, thus leading to fights and little unity of purpose.

By contrast, English commanders were first and foremost sailors, usually having served on ships since boyhood and intimately knowing all the details of sailing. Likewise, English crews were all sailors and even gentlemen were expected to "haul a draw" as seen in an apology by a certain Lord Henry Seymour for not writing a letter with his own hand, since he had hurt it "hauling a rope". English ships had one sailor per two tons of ship, while Spanish ships only had one for

every seven tons, often having to rely on help from inexperienced and resentful soldiers. In short, each English ship was under a unified command with a unified purpose. Spanish ships weren't.

Revolutionary new cannons. The recovery in 2008 of two cannons from a sunken Elizabethan ship, the *Alderney*, indicate the English were developing deadly new cast iron cannons that already were giving their navy a reputation as something to avoid by the time of the Armada. For one thing, they had figured out that a lot of smaller guns were more effective than a few big ones. They were also casting guns of a standard size that would use standard gauge ammunition, a development 50 years ahead of their time. Tests on full size replicas of these new, smaller cast iron guns show they had a range of one mile, but a cannonball fired at 100 meters could tear through a solid oak hull, cross the deck and tear its way out the other side. Previously it was known that English warships were greatly feared, but until the discovery of the *Alderney*, it was not known why.

Sixteenth century gunnery. Not that the English had everything worked out. Gunnery, in particular was highly inaccurate for several reasons. For one thing, gunpowder was expensive, so gun crews had little or no practice before battles. Also, non-standardized and unreliable gunpowder made it hard to estimate the range to targets. One charge of powder might barely push a cannonball out the barrel, while another might blow up the whole gun. Finally, the rocking of the ships combined with the time it took for fuses to burn down made it hard to time shots so they would fire on the proper trajectory. Therefore, it was by no means certain that this new approach to naval warfare would work against the tried and true methods of the Spanish Armada.

Philip's grand strategy was to send the Armada to pick up the Spanish Army of Flanders which was then fighting the Dutch, transport it to England to crush the English and replace Elizabeth with a Catholic ruler, and then bring the Armada back to crush the Dutch rebels and French

Huguenots. Thus the Armada presented a serious threat, not just to England, but also to the very existence of Protestantism in Europe.

On July 31, 1588, the English sighted the Armada off Plymouth and sent the news to London by a series of watch fires. Both fleets would be in for a surprise when they met. The Spanish were thrown off by the speed and maneuverability of the English ships, which they couldn't come to grips with in order to board. Similarly, because the Armada sailed in a tight crescent formation with a powerful center, extended horns, and its twenty best ships operating independently in front or behind as needed, the English couldn't isolate individual ships that they could then pound from all sides with their artillery.

Therefore, the first week of fighting was a running battle up the Channel, with neither side making much impact on the other. The English would pick off an occasional straggler or damaged ship, such as when two Spanish ships were damaged in a collision and another was damaged and sunk when its powder magazine blew up. However, they were failing in their primary goal, which was to prevent the Armada from reaching the Netherlands and picking up the Spanish army of Flanders. Therefore, time was running short for the English as the Spanish pulled into the harbor of Calais to regroup and try to establish contact with the Duke of Parma.

The Armada's commander, Medina Sidonia, who mistakenly assumed that Parma knew of his approach and would be ready to rendezvous with him, finally got a letter from Parma saying his army wouldn't be ready for another week, having dispersed it to disguise the intended invasion of England.

On August 8, with a westerly wind and high tide with them, the English, desperate to force the issue, launched eight fire ships to flush the Spanish ships out of harbor and hopefully out of formation. It worked better than they may have expected, because of two words: Giambelli's hellburners.

The Spanish managed to divert the first two fire ships out of harm's way, and were about to latch onto and divert the next two, when a charge of powder exploded on one of the ships. Their immediate thought was that these were more of Giambelli's hellburners such as had wrecked the Duke of Parma's bridge at Antwerp four years earlier.

In fact, Giambelli was working for the English, but on a project to build a bridge not destroy one. However, although these were not some of his hellburners, the terror invoked by his name was enough to paralyze the Spanish crews in charge of diverting the fire ships long enough to let them through to the Armada.

Therefore, the fire ships did their job of forcing the Spanish ships out into the open and out of formation where the English could use their superior firepower and speed to destroy them ship-by-ship.

Luckily for the Spanish, The English Lord Admiral Howard got distracted by trying to plunder a Spanish galleass with a damaged rudder and mainsail. His boarding party took the ship, but this led to a scrape with the neutral French whose waters this was in and who wanted the prize. This whole fiasco gave the Spanish two hours to partially regroup into formation before the actual battle began.

The ensuing Battle of Gravelines was a running battle up a treacherous coast made more treacherous for the Spanish by the Dutch who had removed the local buoys marking the

locations of dangerous rocks and reefs. This helped the English do great damage to the Spanish, especially their frontline ships defending the rest of the Armada.

One ship, the *San Martin*, was hit with 200 shots, forcing divers to patch its holes at the waterline. Meanwhile, a pack of English galleons pounded another ship, the *San Mateo*, until "*she was a thing of pity to see, riddled w/shot like a sieve.*" The recoil of its guns ripped them loose from the hull, pulling it apart. As the English realized how helpless many of the Spanish ships were, they moved in closer to fire at a much deadlier range. The Spanish fought valiantly, even firing their muskets in the face of the much more devastating cannon fire of the English.

Then a storm blew up from the northwest forcing the two navies to break off. While the English could head for safe home harbors, the Spanish had no such option and had to head out to the open sea to avoid the treacherous Flemish coast.

Having had their fill of the English navy and given up on meeting the Duke of Parma, the Spanish kept heading north, eventually to sail all the way around Scotland and Ireland to get home.

As successful as the English were in the Battle of Gravelines, they only sank one ship. They might have sunk more if the battle hadn't been interrupted by the storm...except for one thing. They were out of gunpowder. And there was no more to be had in all of England. (In fact, 25% of the powder they used at Gravelines was what they had captured from the Spanish in earlier fights. If the Spanish had known, they could have sailed in and had England for the taking.

As it was, their stormy journey back to Spain was what really wrecked the Armada, only half of its 130 ships making it home. Spaniards shipwrecked off the coasts of Scotland and Ireland were usually killed, although some Irish, being sympathetic to fellow Catholics, took them in and hid them. After that, any Irish children

born with black hair were rumored to have Spanish blood in them.

While England's radical new approach to fighting at sea had not in itself destroyed the Armada, sinking only one ship at Gravelines, it did point the way to a new era in naval warfare dominated by increasingly larger ships relying on firepower instead of boarding and grappling.

Nor did the defeat of the Spanish Armada destroy Spain as a great power. However, it did signal the beginning of the end of Spanish dominance of Europe. In the first half of the 1600's this process would accelerate as Spain wrecked itself by trying to maintain its power in an exhaustive and devastating series of conflicts, most notably the Thirty Years War (1618-48).

As a result, a new balance of power would emerge in Europe. France would replace Spain as the main superpower, while the Dutch Republic and then England, despite their small size, would become the most dynamic naval and economic powers in Europe.

Europe's mentality would also change in the 1600's. Exhausted and disgusted by the seemingly endless religious wars and disputes, many people would take a more secular (worldly) view of things, seeing religion more as a source of trouble than comfort. By the late 1600's, these views would flower in the great scientific and cultural movement known as the Enlightenment.

THE THIRTY YEARS WAR (1618-1648)

Introduction. The last half of the 1500's saw Europe embroiled in a number of religious conflicts. For the most part, these wars were either between two countries (e.g., England vs. Spain, the Dutch vs. Spain) or internal affairs with some outside interference (e.g., France and Germany). However, as the seventeenth century dawned, religious and political tensions grew to encompass all of Europe in an interlocking network of states extending from Russia to England and from Sweden to Spain. These tensions exploded into what can be seen as the first European wide conflict in history: the Thirty Years War (1618-48).

A Brutal Century

The outbreak of the Plague in Naples

The 1600s were brutal times, the years 1618-48 marked by the first European-wide conflict, the Thirty Years War, the second half of the century dominated by the massive destruction and bloodshed of Louis XIV's wars.

The climate also turned colder. Even the lagoons of Venice froze over, as did the Baltic Sea, providing a convenient invasion route for the Swedes into Russia. And with colder weather came famine, and with that came epidemic. The Black Death made its last major appearance in the 1600s, claiming 100,000 lives in London (1665), 130,000 in Naples (1656), 30% of Stockholm's population (1710-11), and 50% of Marseilles' (1720-21) before virtually disappearing from the scene.

There were other diseases to take its place, though. Poor sanitation nourished lice carrying typhus, rats and fleas carrying plague, and mosquitoes carrying malaria. Piles of horse manure in the streets bred flies, leading to

typhoid and infantile diarrhea that killed thousands of children. Smallpox was especially prevalent, claiming an estimated 1 in 14 lives and leaving its survivors, such as Louis XIV & Charles XII of Sweden, pockmarked for life.

From 1648-1713 it is estimated that Europe's population fell from 118 million to 102 million. For most people life was a desperate struggle for survival. In the words of the 17th century philosopher, Thomas Hobbes, it was "*solitary, poor, nasty, brutish, and short.*"

The rich and famous might look forward to a life of 50 years or so if they survived the first year of life. Up to one-half of all infants did not.

- Peter the Great and his second wife Catherine had 12 children. Only 2 daughters reached adulthood.
- Queen Anne of England had 16 children...all dead by age 10.
- Louis XIV and his queen Maria Theresa had five children. One survived.
- Within 14 months Louis lost his only son, eldest grandson, and eldest great-grandson-- all to measles.

For most people the day ended when the sun went down and their world was plunged into a darkness populated by witches and demons.

The great events of the day were beyond the narrow horizon of the vast majority of people...unless those events came with fire and sword.

Even the heavens seemed to portend calamity, as the appearance of Halley's Comet in 1618 added to already growing anxiety about coming disaster.

A growing fear of war triggered an arms race, as each ruler seemed armed to the teeth to protect himself from his neighbors. Demonstrations of military power, such as the one at Nuremburg

pictured below, were meant to deter aggression. Unfortunately they only alarmed their neighbors and fed a vicious cycle that saw military stockpiles and tensions rising together.

In the early 1600s people expected war to come in 1621 when the truce between Spain and the Dutch (United Provinces) expired. Indeed it would have if not for events in Bohemia in 1618.

Causes and outbreak of war. The roots of the Thirty Years War extended back to two main developments in the 1500's: the religious wars emanating from the Protestant and Catholic Reformations, and fear of Hapsburg Spain and Austria, who between them controlled nearly half of Western Europe. Religious tensions (complicated by political rivalries) led to conflicts between Lutheran Sweden and Catholic Poland, German Protestants and Catholics, and the Protestant Dutch and English against Catholic Spain. Fear of the Hapsburgs also contributed to the English and Dutch conflicts with Spain. In addition, France, once it had recovered from its own religious wars, increasingly took the lead against the Spanish and Austrian Hapsburgs who ringed its borders to the north, south, and east. Venice also had problems with Austria over pirates in the Adriatic.

All these tangled religious and political tensions of the early 1600's polarized Europe into two camps defined largely, but not exclusively, by religion. The Protestant camp consisted of German Protestants, Denmark, the Dutch Republic, England, Sweden, Catholic Venice, and Catholic France. The Catholic camp had German Catholics, Spain, Austria, the Spanish Netherlands, Naples, Milan, the Papacy, and Poland.

Two such hostile camps staring menacingly at one another led to the common fear and expectation of a general war embroiling all of Europe. As a result, kings and princes built up armies and fortifications in preparation for the coming war, which merely reinforced the other side's fears of war, triggering more military spending and so on. Travelers of the time noted how states all over Europe seemed to be armed to the teeth and ready for a fight. This was especially true in Germany where the Protestant princes formed a defensive league known as the Protestant Union in 1609 while the Catholic princes quickly answered with the Catholic League.

Added to this were two other factors making Europe's economy less vibrant than it had been in the 1500's. For one thing, the flow of silver from the Americas had passed its peak. For another, the climate turned colder, reducing crop yields and straining Europe's ability to feed its population (which had doubled since 1450). This, in turn, led to lower resistance to disease (including Bubonic Plague which made a comeback in the 1600's). The combination of soaring military budgets, declining silver production, and the effects of a colder climate led to rising tensions in Europe, both between different states and between social classes within individual societies.

These problems combined with the fact that Europe was split between two hostile political/religious camps meant that any conflict or crisis between individual members of each camp could drag in all the other members of their respective camps and trigger a European wide war. In this respect, the situation largely resembled the one that would drag Europe into World War I in 1914.

In 1618, Protestants in Bohemia, which was part of the Holy Roman Empire, rebelled against the Austrian Hapsburgs. Unfortunately, Germany's fragmented political situation generated a vicious cycle that would turn a local struggle into a European wide conflict using Germany as its battleground. As the crisis grew, more states would get involved and commit increasing amounts of resources. As more allies joined each side, the war grew into an exhausting stalemate that no one could either win or afford to quit since they had already spent so much on it and felt they had to recover its expenses from its enemies. Concern over a Protestant or Hapsburg Catholic victory and belief that the balance could be tipped to their advantage would draw in more powers, eat up more resources, perpetuate the stalemate, and so on.

Thus Spain, Poland, the German Catholics, and the Pope came to Austria's aid to crush the Bohemian rebels. This caused Denmark, England and the Dutch Republic to join the conflict against the Hapsburgs, but they were defeated. Then Sweden attacked Austria, supposedly in defense of the German Protestants, but was eventually defeated. Finally, Catholic France threw itself into the fray, helping the Protestants against the Hapsburgs. Each

new power getting involved merely fed more fuel into a veritable firestorm of continuing stalemate until there was hardly anything left to burn.

More and more, this has become the pattern of modern warfare, as its expense makes it too expensive to fight, but also too costly to back out once a country has committed itself to it. And as the cost and destructiveness of war goes up, the spoils of war to make it pay for itself dwindle correspondingly. This dilemma has increasingly plagued modern warfare to the present day, as the technology of war has gotten progressively more destructive and expensive, both to build and use.

Opening phases of the war (1618-35). Many people figured war would start in 1621 when a truce between the Dutch Republic and Spain was due to expire. In fact, it started in Bohemia (the modern Czech Republic) and Germany over the succession to the crown of the Holy Roman Empire that the Hapsburgs had held for generations. However, there was no guarantee the electors would choose another Hapsburg when the old emperor Matthias died. Since six of the seven imperial electoral votes would likely be split between three Catholic and three Protestant electors, the Bohemian king's electoral vote could be the decisive one.

Here was where the trouble began, because Ferdinand of Styria, the king of Bohemia and heir apparent to Matthias, was an ardent Catholic, whereas Bohemia had been a hotbed of religious turmoil ever since the Hussite revolt in the early 1400's. When Ferdinand tried to end the Protestant Bohemians' religious freedom, they retaliated by defenestrating (throwing out a window) two imperial ministers in the famous Defenestration of Prague (1618) and deposing Ferdinand as their king. Although the ministers miraculously survived the sixty-foot fall, the peace did not survive with them as the turmoil quickly spread across Germany.

Unfortunately for the Bohemians, when they rebelled against Austria, they elected a mediocre king, Frederick of the Palatinate, who only brought moral support from other Protestant powers. Cossack raids stirred up by Poland diverted the one bit of substantial help they might have gotten, troops from Transylvania. Meanwhile, Spain, Bavaria (as head of the German Catholic League), and the Pope were helping Austria with men and

money. Consequently, the Bohemian War (1618-22) was not much of a struggle as Ferdinand (who had since become emperor) easily swept away Bohemian opposition. Ferdinand and his allies confiscated large tracts of land, exiled Protestants, and reclaimed Bohemia for the Catholic Church.

However, growing fear of a resurgent Hapsburg dominance stirred up activity across Europe in two main theaters of war, one aimed against Spain and the other against Austria. First of all, hostilities between Spain and the Dutch Republic resumed as expected in 1621 when their truce ran out. England also declared war on Spain in 1625 and joined the Dutch in a raid on Cadiz that ended in an embarrassing defeat for the Dutch and English. After this, England became more involved in its own religious and political squabbles that culminated in civil war in the 1640's. This kept them from playing any major role in the wider conflict unfolding on the continent.

Meanwhile, France was also active, fighting Spain over strategic towns and passes in Italy. If the French could control this area, they could block the flow of Spanish troops to the Netherlands along the so-called Spanish Road. However, France's effort was somewhat ineffective at this point, largely because of turmoil at court. Cardinal Richelieu, who wanted to commit France wholeheartedly to fight the Hapsburgs, had to fight for his own political life against the Queen mother, Marie de Medici. Richelieu and his policy would eventually triumph, throwing the full weight of France against the Hapsburgs with momentous results for European history. But for now, France's effort was of little account, and Spain held on in Italy.

Despite these victories, ten years of warfare were taking their toll on Spain's wealth, manpower, and ability to protect its treasure fleet, which the Dutch captured for the first time in 1629. This and Spain's already seriously damaged finances forced it to declare bankruptcy, leaving outstanding loans unpaid.

Meanwhile, the Austrian Hapsburgs' overwhelming victory in Bohemia had led Denmark to invade Germany in 1625 supposedly in defense of Protestant liberties. The Hapsburg general, Albrecht von Wallenstein, and the Catholic League's general, Tilly, made short work of the

Danes, thus winning what is known as the Danish phase of the war (1625-29). The emperor Ferdinand felt so strong after his victory that he issued the Edict of Restitution in 1630. This declared that all land taken from the Catholic Church since 1555 must be returned to the Church. The Edict of Restitution drove thousands of Protestants from their homes and aggravated an already turbulent situation. It also alarmed and angered German princes, Catholic and Protestant alike, who felt the emperor was overstepping his constitutional powers.

At this point Sweden, prodded by fear of Austria's growing power, Spain's apparent weakness, and France's willingness to back it with money, threw in its lot against the Hapsburgs and invaded Germany. This transformed what was already a European wide affair into a prolonged and bloody war of attrition where neither side was able to win a quick decisive victory or willing to concede defeat. To the German people caught in the middle, the war seemed to have assumed a life of its own that would carry on until there was nothing left in Germany to sustain it.

Sweden was a relative newcomer to European diplomacy. However, thanks to a line of brilliant and ambitious kings, the "Swedish meteor" would burn brightly over the Baltic before fizzling out in the 1700's. Two other Baltic states, Poland and Russia, were also assuming greater roles in European affairs. As a result, events in Eastern Europe and the Baltic had a growing impact on events in Western Europe. At this point, it was peace between Sweden and Poland that freed Sweden to invade Germany.

Sweden's king, Gustavus Adolphus, was a brilliant and daring general with a highly trained and disciplined army at his back. He used Swedish draftees rather than unreliable mercenaries and put them in smaller units that could more effectively use their numbers and firepower. He further increased this firepower by experimenting with mobile field artillery that could wreak havoc on the massed formations of the day. These reforms proved their worth at the battle of Breitenfeld (1631) where Swedish discipline and firepower overcame the desertion of their Saxon allies to crush an imperial army under Tilly. The next year Swedish tactics won a bloody but costly victory at

Lutzen. In the smoke and confusion of battle, Gustavus was killed, taking a good part of the heart out of the Swedish effort.

Nevertheless, the Swedes pressed on, devastating Catholic lands on the way. Austria enticed its ally and Sweden's enemy, Poland, into the war, but a war further east against Russia neutralized the Poles. This prompted Spain to send an army north to retrieve the situation in Germany and the Netherlands. In 1634, the Spanish army crushed the Swedes at Nordlingen. The Swedes launched some fifteen heroic, but basically suicidal charges against the Spanish positions, all with disastrous results.

The war of attrition (1635-48). Once again, the Protestant cause seemed on the verge of collapse. The war had raged now for some sixteen years. Hundreds of German towns and villages were devastated, and whole regions were virtually depopulated. The war's destruction and upheaval brought famine, and with that came disease. Germany was ready for peace. Unfortunately, the other powers in Europe were not. Instead, the war was about to enter a much more destructive phase of attrition where each side, instead of expecting a quick and decisive victory, fought to wear down the other side no matter what the cost might be to themselves.

In 1635, France wholeheartedly entered the war, ending any hopes for a quick peace. Its strategy was still largely to fund two of Spain's enemies, the Dutch and Swedes, and let them do as much of the fighting as possible. At first its own armies were somewhat ineffective against Spain's veteran troops. However, the Swedes, bolstered by French funds, beat the imperialists at Wittstock (1636) and forced an invading Spanish army to withdraw from France. This in turn allowed the French to invade Spain to support a revolt in Catalonia.

Meanwhile, the Dutch had dealt a crippling blow to the Spanish war effort by destroying a Spanish armada of 77 ships at the Battle of the Downs (1639). The next year, the Dutch crushed another Spanish and Portuguese fleet off the coast of Brazil. These two naval battles had the double effect of permanently wrecking Spanish naval power in the Atlantic and triggering a Portuguese revolt.

Even for the victors, this war was exhausting and ruinous, and by 1640 most powers were ready for peace. However, several things prevented peace at this time. First of all, the tangled alliances kept any one power on one side from negotiating its own separate peace. Second, rulers had a limited resource base with which to pay for the war, and that was shrinking steadily as the war's destruction ate up those resources. This helped generate the vicious cycle of stalemate discussed above.

However, with each year, the tide of war was shifting more and more against the Hapsburgs. In Germany, the Swedes beat an Imperialist army at the Second Battle of Breitenfeld (1642), which caused most of Austria's German allies to desert it. In 1643, the French crushed a Spanish army at Rocroi, opening the way to invade the Spanish Netherlands and establish France as the premier power in Europe for decades.

With Spain on the verge of bankruptcy and collapse, Sweden's manpower depleted, and even France facing tax revolts, everyone agreed to start negotiations at Westphalia in 1645. Even then, heavy French and Swedish demands for land and money, Austrian reluctance to give up, and the fact that neutral Germany was the battleground caused the negotiations to drag out as the war dragged on.

End of the war and its results. In 1648, the Dutch finally made a separate peace with Spain, gaining recognition of their independence after an 80-year struggle (1567-1648). This and the growing threat of revolt in its own lands prompted France at last to come to terms that same year. The resulting treaty became known as the Peace of Westphalia.

The Peace of Westphalia symbolized and confirmed the great changes taking place in Europe's balance of power over the first half of the 1600's. Spain, bankrupt and exhausted, was now reduced to the level of a second-class power. Austria's influence was virtually destroyed in the Holy Roman Empire. However, it would find new life by expanding eastward against an even more corrupt and decaying power, the Ottoman Turks. Germany, whose population and property had suffered damages only surpassed by that of World War II, remained hopelessly broken into some 300 states. Yet out of the ashes of this destruction Brandenburg-Prussia would gradually emerge to unify Germany in 1871.

There were winners. Sweden emerged as the dominant power in the Baltic for another half century. However, by the early 1700's, its aggressive policies would wear it out and knock it out of the mainstream of European politics. The Dutch came out of the war in the best shape of any country in Europe. Dutch trade and economy actually flourished during the war, making enormous profits from raiding Spanish shipping, taking over Spain's colonial trade, and selling munitions to the various combatants, including Spain.

Politically, France was the big winner, severely weakening the ring of Hapsburg powers surrounding it as well as gaining territories along the Rhine. All this also had its cost. For one thing, France's war with Spain dragged on until 1659. Secondly, the terrible tax burden of the war triggered a revolt known as the Fronde (1648-53) that nearly toppled the monarchy of the young Louis XIV. As it was, Louis' monarchy emerged triumphant (unlike its counterpart in England also facing revolution), and France emerged as the dominant power in Europe. The age of Spain was giving way to the age of France.

The Storm breaks: Bohemia (1618-23)

At this time, the balance of power between Catholics and Protestants in Europe centered largely on events in Germany, which was split fairly evenly between the two faiths. Similarly, Germany's balance of power (political and religious) rested largely with seven electors who would choose the Holy Roman Emperor, when the old and childless emperor, Matthias, died. Since three electors were Protestant princes and

three others were Catholic archbishops, the key to *that* balance rested with the king of Bohemia, a staunchly Protestant land whose elective king, Ferdinand of Styria, was also the heir apparent to the Austrian Hapsburg lands.

Two things added further to the rising tensions and uncertainty. One was the emperor Matthias' Letter of Majesty in 1609, which granted the Bohemians religious freedom. Secondly, Ferdinand of Styria, a fervent Catholic, revoked that freedom.

The Defenestration of Prague).

In 1618 Bohemians in Prague retaliated by defenestrating (tossing out a window) two Catholic ministers. Miraculously they survived the 60-foot fall, Catholics claiming they were caught by angels, Protestants saying they landed in a dung heap under the window. Ferdinand rewarded the ministers for their trouble by giving them each the noble title von Hohenfall (of the Great fall). Whatever broke their fall, the Defenestration of Prague triggered the Bohemian Revolt which would escalate into the Thirty Years War, the first European-wide conflict.

Having deposed Ferdinand of Styria, the Bohemians elected Frederick, the Protestant elector of the Palatinate as their new king. Unfortunately, Frederick failed to supply the type of leadership the Bohemians needed for their revolt to succeed. His father-in-law, James I of England, was too remote and too preoccupied with other matters to worry about Germany.

One hundred thousand English ambassadors. Ferdinand, had few troops of his own and had to rely on Maximilian of Bavaria, the leader of the Catholic League in Germany and its army, the largest in Germany at that time. He also got

support from his Spanish cousins, the Pope, and Poland. By contrast, the Bohemians got virtually no support. A Jesuit play of the time made fun of this by having a messenger tell Frederick that he would get help in the form of 100,000 herring from Denmark, 100,000 cheeses from the Dutch, and 100,000 ambassadors from the English.

Imperial forces effectively crushed the Bohemians at the Battle of White Mountain. Frederick of the Palatinate's electoral vote was given to the Catholic Maximilian of Bavaria, while the Jesuits were unleashed on Bohemia to bring it back into the folds of the Catholic Church.

The Danish Phase & Golden Bird (1625-9)

Suppression of the Bohemian Revolt was not the end of hostilities. Growing Hapsburg power now alarmed Protestants outside of Germany. Enter Christian IV of Denmark, who had a well-organized nation-state & thought he could challenge growing Hapsburg power in Germany. Christian thought he would be welcomed as a champion of German liberties. However, he was sorely disappointed at the lukewarm reception he got from German Protestants who were nearly as suspicious of Danish intentions as they were of the Hapsburgs.

The Danish attack brought to prominence Albrecht von Wallenstein, a devious, opportunistic, and highly superstitious general who led the Hapsburg armies. Originally a

Calvinist, he converted to Catholicism in time to cash in on the rush for lands confiscated after the Bohemian revolt. The huge estates he got enabled him to supply large forces, a key to any general's success during the 30 years War when the state rarely could do so consistently.

However, in 1628, the Dutch dealt a crippling blow to Spain by capturing its entire treasure fleet, known as the Golden Bird. Spain also was involved in minor conflicts with France over Alpine mountain passes that were crucial for supplying and communicating with its army in the Spanish Netherlands. Therefore, despite Hapsburg victories in Germany, Spain was starting to feel the pinch. However, the fighting had hardly begun.

The Edict of Restitution (1630). In 1630, the emperor Ferdinand II, feeling confident after two easy victories, issued the Edict of Restitution (1630), which restored all Catholic lands lost to the Protestants since the Peace of Augsburg in 1555. Because of this, the Church reclaimed the lands of 2 archbishops, 12 bishops, & 500 monasteries, thus turning thousands of German Protestants into refugees. Also, since he didn't first consult the German Diet, Catholic and Protestant nobles alike were mad.

The "Lion of the North": Sweden (1630-35)

Into the fray stepped the fiery and charismatic king of Sweden, Gustavus Adolphus (1611-32), probably the most celebrated figure of the Thirty Years War. Since coming to the throne in 1611 at age 17, he already had twenty years of military experience fighting the Poles before he brought the Swedish army into Germany.

Although a strict disciplinarian, several things endeared Gustavus to his soldiers. For one

thing, he looked after their creature comforts, getting them the best food, blankets, and clothes he could as well as waterproof Russian boots. He shared their hardships, even digging trenches with them.

He was also a great general, and soldiers always love to follow a winner, especially one that personally leads them in battle. Once when urged to stay out of danger, he replied he wouldn't be a "king in a box". This was a trait that both endeared him to his men and would cost him his life.

Gustavus was so respected that an Italian mercenary hired to kill him couldn't pull the trigger when he had him in his sights. Even the emperor, Ferdinand II, was said to have cried upon hearing of Gustavus' death in battle.

The Swedish army was somewhat unique as well, being a truly national army consisting of draftees rather than mercenaries. Training and discipline were especially strict, although the Swedes would gain a reputation for being especially ferocious when turned loose on the civilian population. In fact, they were so notorious for their brutality that German mothers would scare their children into behaving with the threat that the Swedes would come in the night and get them.

Much of Gustavus' success was due to his prime minister, Axel Oxenstierna (1583-1654), a cool calculating diplomat who served as the perfect complement to the fiery Gustavus. It was Oxenstierna who laid the diplomatic groundwork, such as the alliance with and monetary support from France, which allowed Gustavus to concentrate on the battlefield.

Gustavus: "If we were all as cold as you, we should freeze."

Oxenstierna: "If we were all as hot as your majesty we should burn."

At this time it was common for rulers to leave much of the responsibility of governing to a prime minister. For example, Louis XIII of France relied heavily on Cardinal Richelieu,

while Oxenstierna's counterpart in Spain was the Count-Duke of Olivares, as portrayed by the great Spanish painter, Velasquez.

The diplomacy at this time was especially complex, since Bavaria & the Catholic League were allied with both France and Austria. ...But France was funding Sweden against Austria and Bavaria ...whose armies were both led by Johann Tserclaes, Count of Tilly against Sweden.

In 1631, the emperor, Ferdinand II, dismissed Wallenstein for his constant intrigues with the enemy. This gave command of the Hapsburg, as well as the Catholic League forces to the Bavarian general, Tilly, known as the Monk in armor for his religious piety.

However, Wallenstein's value as a general had been his ability to supply his army from his extensive lands in Bohemia. Now that he was gone, those resources were no longer available, so Tilly had to find another source of food for his hungry army. Believing the town of Magdeburg had food, he put it under siege. Magdeburg tried to hold out until Gustavus Adolphus came to the rescue, but two breaches in the city wall let in the hungry imperialist troops.

What ensued was one of the worst disasters of the Thirty Years War. It was a windy day and a fire broke out in the confusion of sacking the town. Unfortunately, the imperial troops were too drunk and out of control to fight the fire that rapidly spread and destroyed the city. Of 30,000 inhabitants, only 5,000 survived, and most of those were women taken captive by the soldiers. Tilly himself, who was seen carrying a baby he

rescued from the flames, sent priests to get his men to marry their captives.

Word of the catastrophe at Magdeburg incensed Protestants, who, whenever asked for quarter by Imperial troops, would kill them with the cry "Magdeburg quarter."

The war had taken a nasty turn for the worse ...and everyone would pay the price.

When the Swedish and Imperialist armies finally clashed at Breitenfeld (9/18/1631), the Swedes arrived with several innovations. For one thing, they were organized in smaller squares that made them more mobile than the huge Spanish *tercios*. Swedish musketeers were also more thoroughly trained in the countermarch. Even their imperialist foes said the Swedes' rate of fire was three times greater than their own.

Also, the Swedish artillery was lighter and more mobile, allowing them to place their cannons in front of the army for the initial bombardment preceding the battle, and then pull it back as the two armies closed in on one another. X-rays of Swedish cannons showed they consisted of several layers of different materials, including leather, which made them strong, but light.

Early in the battle, the Swedes' Saxon allies were panicked by the wild charge of the imperialists' Croatian cavalry, with their red cloaks and demonic sounding battle cries, thus leaving the Swedes' left flank exposed.

This is where the Swedes' training really told as they adjusted to fill the gap and maintained a relentless rate of fire to hammer the enemy attacks to a standstill. Gustavus seemed to be everywhere, rallying his army until the opportune moment arrived for a counter-attack. Finally, late in the day, with the sun and dust in the Imperialists' faces, he led a cavalry charge that broke the enemy.

By nightfall, the Imperialists had suffered 12,000 casualties and lost another 7,000 prisoners, most of whom were Swedish soldiers by the following morning. The next year, the Catholic general, Tilly, would be fatally wounded by a cannonball in another battle, his right arm being shattered.

This was the Protestants' first major victory in the war, and everything seemed to cave in on the Imperialists who, for the first time, saw the war taken to their lands. Wallenstein reinstated as general by Ferdinand, met Gustavus at the battle of Lutzen in 1632. To make his army look bigger, Wallenstein pressed the local peasants into squares, and then burned their homes so the smoke would blow into the Swedes' faces.

As always, Gustavus was in the thick of the action. At one point, he led a charge and disappeared into the smoke, but only his horse returned. Enraged at their leader's death, the Swedes rallied to lay one more victory at their fallen king's grave. However, it was a hollow victory that took the heart out of the Swedish war effort.

Wallenstein didn't survive Gustavus Adolphus by long. His continual intrigues finally convinced Ferdinand to have him killed. One night, a group of mercenaries broke into Wallenstein's headquarters, cut him down, and rolled his body up into a rug. Of the nine soldiers who finished Wallenstein off, three were Scottish and four were Irish, showing the strong involvement of mercenaries from the British Isles, even if England itself was preoccupied with other affairs.

Meanwhile, Spanish reinforcements arrived to bolster the Imperialists' cause. At Nordlingen in 1634, the outnumbered Swedes launched no fewer than 15 desperate but suicidal attacks against the Spanish position. By the day's end,

their army of 25,000 men had lost 17,000 men, and the Protestant cause again lay in ruins.

Once again help arrived just as the Protestant cause seemed hopeless.

The Dogs of War

The Thirty Years War was a major disaster for Germany's population. However, it was no picnic for its soldiers, regardless of what the recruiting officers promised

Early in the war recruiters used music, colorful banners, and promises of glory and riches to attract naïve young men to enlist. However, as the war dragged on and it became increasingly harder to find willing recruits, recruiters replaced banners and music with gallows next to their tables as a subtle inducement to enlist.

Throughout most of history, the majority of time for soldiers has been spent in the boredom of camp. The Thirty Years War was no different, as soldiers whiled away their days with gambling, drinking, getting drunk and fighting over gambling gone bad, and picking fleas off their bodies. Since they were not consistently paid and supplied, they had to rely on traveling merchants, known as sutlers, to sell them clothes, food, and other day to day needs...often at exorbitant prices of course.

Not that battle wasn't bad enough. As one contemporary account described it: *"The cruel shots, the crashing of armor plates, the splintering of pikestaves, the screams of the attackers as well as the wounded, the blare of trumpets, the roll of drums, the shrill sound of fifes..." so that when over..." the earth that is accustomed to covering the dead was herself now covered with corpses."*

"Young soldier, old beggar" Despite promises of glory and riches to young recruits, most veterans ended up impoverished and often disabled. If wounded, the crude and brutal nature of battlefield surgery seemed to do all it could to ensure a prolonged death or miserable survival. Wounds typically required amputating the affected limbs to prevent infection from gangrene. Cauterizing them often involved

sprinkling the wound with gunpowder and lighting it, the shock of the explosion sometimes killing the patient.

However, as always, the big killer of soldiers was a not wound from battle, but disease. An army might lose 20-25% of its numbers a year, and 5% a month if it campaigned in the winter months.

One study of a Swedish village showed that of 230 recruits taken to war, only 15 eventually returned. In 1639, half the recruits were under the age of 15. Only 2 were over 18.

Many veterans went to monasteries where they intimidated and beat up the monks while stealing the food and drink. In France, the Church agreed to pay for a hospital for disabled veterans if the king would run it and take the veterans out of the monasteries. Thus was born the *Invalides*, the first veterans' hospital.

Casualties of War: The Four Horsemen of the Apocalypse. Fighting in the Thirty Years War consisted more of skirmishes and raids than it did of a few major pitched battles. Therefore many civilians had to deal head-on with war as a chronic problem rather than something to avoid just a few days a year.

Because of its scale and cost, the Thirty Years War seemed to assume a life of its own where neither side could either win a decisive victory or afford to quit. The abuses and atrocities of this war were nothing new. What made it unique was its prolonged nature, which multiplied its abuses many times over what had ever been seen before.

The ravages of plundering mercenaries in the Thirty Years War left hunger and disease in their wake, depopulating many areas of Germany by as much as 60%. The Palatinate may have lost as much as 98% of its population.

Pleas by the peasants for mercy were rarely heeded. Many peasants, having lost their homes, fled to the woods to subsist on whatever they could find there. When given the chance, they would take vengeance on stragglers, no matter

which side they supposedly represented. Some peasants even organized to defend their homes against both sides in the war (below).

Since plundering was technically against regulations, officers would occasionally crack down when it got especially out of hand. A few unlucky soldiers would be caught and hanged, serving as a very temporary warning to the others. One of the most notorious and feared military punishments was the dreaded “Swedish drink”, a mixture of excrement forcibly poured down a soldier’s throat.

The War of Attrition...and Peace (1635-48)

France’s entry into the war was a gradual process, largely because it was still trying to recover from its own Religious Wars. It had been funding Sweden’s war effort since 1631, and Louis XIII’s minister, Cardinal Richelieu, pushed for a more aggressive policy to stop the Hapsburgs.

It largely came down to a power struggle between Richelieu & the king’s mother, Marie de Medici, who wanted France to stay out of war. Marie expected her son to side with her, but on the “Day of the Dupes”, she lost out to Richelieu and was sent to an internal exile on a country estate.

France had chosen war.

Even after entering the war, France eased into its role by funding the Swedes and the Dutch against the Hapsburgs.

The Dutch certainly did their part. In 1639, they destroyed 70 out of 77 Spanish ships at the Battle of the Downs. The next year (1640) they destroyed another Spanish squadron off the coast of Brazil. These defeats triggered revolts in Portugal & Catalonia in 1640 further wearing down the Spanish.

All these disasters piled on top of one another, along with depopulation from famine and plague in the early 1600s, left Spain exhausted...but not ready to give up.

Events in Germany were going no better. At Wittstock (1636) the Protestants won their first major victory since Breitenfeld, capturing 133 enemy cannons. Wittstock both forced the Spanish army to withdraw from France and revived Sweden's military reputation. At the Second battle of Breitenfeld in 1642, the Swedes again triumphed, despite the imperialists' use of chain shot (two cannonballs chained together and fired from one cannon).

In 1643, the French crushed the Spanish at the battle of Rocroi, a battle that is generally seen as signaling the end of Spanish greatness. At the time of the battle, the dying Louis XIII, supposedly had a vision of France winning a great victory.

Finally, in 1645, both sides, exhausted by war, sat down to peace talks. However, each party came to the talks with the intention of gaining as much and compromising as little as possible.

France and Sweden each had the scent of blood in their nostrils, having gained the upper hand in the war, and made stiff demands for land and money to pay for their troubles.

Austria and Spain were like rats trapped in a corner, desperate and still dangerous, and not willing to compromise their long-standing imperial positions, even though the foundations for those imperial positions were rapidly crumbling away.

And in the middle was Germany, or, more properly, 300 German states: powerless to stop the armies rampaging over their soil while

providing a convenient neutral battleground on which other countries could do their dirty work.

So for three more years, the diplomats wrangled, the armies kept fighting, the soldiers plundered...and Germany bled.

But exhaustion was doing its job on even the big powers, especially Spain & Austria, but also France, which was seething with revolt. Thus, when the Dutch and Spanish signed the Treaty of Munster in 1648, finally granting independence to the Dutch Republic after 80 years of struggle, this prompted parallel negotiations a few miles away at Westphalia to put a final end to the war in Germany.

The Price of War

For England, war in the 1540s raised expenses to ten times Henry VIII's normal income, forcing him to sell Church lands, seize estates, force loans, and debase the coinage. Luckily, peace prevailed from 1558 to 1580, and the treasury recovered. However, when war with Spain broke out under Elizabeth, expenses rose from £50,000 in 1580 to £500,000 (1600).

France told a similar story, but grimmer. By 1596 the French crown had accumulated a debt of 100 million *livres*. Its yearly revenue was 31 million *livres* of which 24 million was already taken by debts. Careful nurturing by Henry IV during a period of peace (1598-1610) led to a partial recovery. Richelieu saw that France was in no shape to fight a major war until 1635, when it entered the war. In 1643, French expenditure was double the crown's income, leading to the Fronde (1648-53), a revolt that nearly toppled the monarchy.

Spain was in even worse shape, despite the silver and gold from the Americas. From 1540-1580, American silver production rose by a factor of ten times to 2 million ducats a year. However, the Armada of 1588 cost 10 million ducats, forcing Philip II to default on his loans in 1596. By 1598, Spain's debt was 100 million ducats, equal to 50 years revenue.

That's if the American mines maintained their productivity. They didn't.

Furthermore, in the 1590s, plague ravaged Spain's population, further reducing its revenues.

In 1607 the Spanish crown defaulted again, forcing it into a 12-year truce with the Dutch. In 1621 war renewed, leading again to lower revenues to cover higher expenses.

So once again in 1627, Spain defaulted on its loans. The next year (1628) the Dutch captured Spain's treasure fleet, dealing it another crippling blow that kept it from being able to pay its armies. As a result, overdue payments for the Army of Flanders triggered 46 mutinies during this era.

In 1643 sixty-five percent of Spain's normal revenue was spent just on interest, causing it to debase its coinage.

By then, silver production was down for good. So was Spain as a major power.

The human cost of the Thirty Years War. But it was Germany that paid the heaviest price. Politically, its 300 states were sovereign, with the right to charge taxes, declare war, etc., which was more of a curse than a blessing to Germany.

Demographically, Germany lost an estimated 30-40% of its population, going from 20 million to 12 million

- Marburg changed hands 11 times.
- Magdeburg was besieged ten times and brutally destroyed.
- Wurttemberg's population fell from 65,400 to 14,800, with half its buildings gone.
- Bohemia lost all but 780,000 of its 3 million people and 85% of its villages.
- Berlin & Colmar lost 50% of their respective populations.
- ^a Chemnitz lost 80%.
- Palatinate lost 98%.

The Swedish army claimed to have destroyed 1500 cities and 18,000 villages.

By 1648, many German peasants were living like wild animals in the woods.

Therefore, when we study how Germany was used as a battleground for the Seven years War and the wars of Louis XIV, the French Revolution, and Napoleon, remember the Thirty Years War.

When we study the rise of Brandenburg-Prussia and the unification of the German State, we should remember the Thirty Years War.

When we study two World Wars I and all their destruction and suffering with Germany at the center, remember the Thirty Years War.

And when we look at the Cold War, Germany's reunification, and painful transition back to nationhood, remember the Thirty Years War.

89. THE COMPARATIVE GEOGRAPHIES AND HISTORIES OF EAST AND WEST EUROPE

Between East and West. Throughout the modern era, there have been striking contrasts between the histories, economies, and politics of Eastern and Western Europe. After World War II, those differences became especially obvious with the Soviet led Warsaw Pact forces poised on one side of the Elbe River and the Western NATO alliance on the other. As so often in history, the underlying basis for these differences has been geography.

First of all, Europe's latitude lies quite far north. For example, Rome, Italy is about as far north as Chicago, Illinois. However, it has a much warmer climate, especially in the winter. This is because Western Europe gets the moderating effects of a warm current known as the South Atlantic Drift and warm sea breezes coming across the Mediterranean from North Africa. Eastern Europe is too far inland to benefit much from either of these effects, and thus has more extremes in climate, especially in the winter.

However, the critical difference between Eastern and Western Europe has to do with waterways. Western Europe has an abundance of navigable rivers, coastlines, and harbors along the Atlantic Ocean and the Mediterranean, North, and Baltic Seas. In the High Middle Ages, these fostered the revival of trade and the rise of towns, a money economy, and a middle class opposed to the feudal structure dominated by the nobles and Church.

Kings also opposed the nobles and the Church, so the middle class townsmen provided them with valuable allies and money. With this money, kings could buy two things. First of all, they could raise mercenary armies armed with guns to limit the power of the nobles. Secondly, they could form professional bureaucracies staffed largely by their middle class allies who were both more efficient since they were literate and more loyal since they were the king's natural allies and dependant on him for their positions. As a result, kings in Western Europe were able to build strong centralized nation-states by the 1600's.

Eastern Europe, in stark contrast to Western Europe, provided practically a mirror image of its historical development before 1600. Being further inland compared to Western Europe hurt Eastern Europe's trade, since the sea and river waterways vital to trade did not exist there in such abundance as they did in Western Europe.

Factors limiting trade also limited the growth of a strong middle class in Eastern Europe. This meant that kings had little in the way of money or allies to help them against the nobles. That in turn meant that peasants had few towns where they could escape the oppression of the nobles. Therefore, strong nobilities plus weak, and oftentimes elective, monarchies were the rule in Eastern Europe before 1600. At the same time, the nobles ruled over peasants whose status actually was sliding deeper into serfdom rather than emerging from it.

However, there was one geographic factor that favored Eastern Europe's rulers after 1600. That was the fact that Eastern Europe is next to Western Europe. As a result, some influence from the West was able to filter in to the East. In particular, Eastern European rulers would emulate their Western counterparts by adopting firearms, mercenary armies, and professional bureaucracies. As a result, they were able to build strongly centralized states in the 1600's and 1700's. This was especially true in three states: Austria-Hungary (the Hapsburg Empire), Brandenburg-Prussia in Germany, and Russia.

However, the lower incidence of towns and a strong middle class has continued to hamper the development of Eastern European states in the modern era, since rulers there have had to build their states with less of the strong foundation of a money based economy, basing their states on less developed agricultural economies. While the strong middle class in Western Europe would provide the impetus for further developments in the West, notably the emergence of democracy and the Industrial Revolution, these two things have had a harder time taking root in Eastern Europe, making its overall political and economic development more difficult.

A Comparison of European and North American Climates

Below are the latitudes and average high and low temperatures in January and July for some select cities in Europe and North America.

Western Europe

| | Latitude | January | July | Avg. rainfall | Record temps |
|---------------------|----------|---------|--------|---------------|--------------|
| <u>Amsterdam</u> | 52° 18N | 34-41° | 55-69° | 32.1" | 3° & 93° |
| <u>London</u> | 51° 09N | 34-44° | 53-71° | 29.7° | 7° & 95° |
| <u>Oslo</u> | 59° 54N | 20-31° | 55-71° | 28.7" | -15 & 95° |
| <u>Tromso, Nor.</u> | 69° 41N | 20-29° | 48-59° | 40.1" | -3 & 82° |

Mediterranean

| | | | | | |
|---------------|---------|--------|--------|-------|------------|
| <u>Madrid</u> | 40° 27N | 32-51° | 61-90° | 17.8" | 14° & 105° |
| <u>Rome</u> | 41° 48N | 38-55° | 64-83° | 31.6" | 19° & 100° |
| <u>Athens</u> | 37° 54N | 44-55° | 72-88° | 14.6" | 25° & 108° |

Central and Eastern Europe

| | | | | | |
|-----------------------|---------|--------|--------|-------|------------|
| <u>Berlin</u> | 52° 23N | 26-35° | 56-73° | 23.7" | -11° & 95° |
| <u>Munich</u> | 48° 08N | 24-36° | 54-72° | 36.5" | -16° & 97° |
| <u>Prague</u> | 50° 06N | 24-34° | 54-72° | 18.8" | -13° & 97° |
| <u>Warsaw</u> | 52° 10N | 24-33° | 55-73° | 21.6" | -23° & 99° |
| <u>St. Petersburg</u> | 59° 55N | 15-24° | 56-70° | 21.2" | -36° & 91° |
| <u>Moscow</u> | 55° 58N | 11-21° | 55-71° | 23.6" | -44° & 95° |

N. America

| | | | | | |

HAPSBURG AUSTRIA RESURGENT (c.1650-1700)

"We came, we saw, God conquered."- Jan Sobieski's announcement of the relief of the siege of Vienna in 1683

After the Thirty Years War and Peace of Westphalia had stifled Austrian ambitions in Germany, the Hapsburgs expanded eastward against the Ottoman Empire. Ever since the death of Suleiman the Magnificent in 1565, the Ottoman Empire had been in decline, with a corrupt government, rebellious army, obsolete military technology, and decaying economy. Such a faltering empire was a tempting target for its neighbors. However, the Hapsburgs were never able to concentrate solely on the Turks. This was because France under Louis XIV posed a constant threat of invasion to the various German states, which forced the Hapsburgs to divide their attention between east and west.

A coin of Leopold I dated 1677, showing Leopold with the distinctive Hapsburg chin (obverse) & the double-headed eagle, symbol of the house of Hapsburg, (reverse)

The Hapsburg ruler at this time was Leopold I (1657-1705), a mediocre ruler, but one lucky enough to have capable generals to lead his armies. Leopold's main goal was control of Hungary, which had been divided between Turkish and Austrian rule for over a century. When Leopold supported rebels in Transylvania against the Turks, war and an Ottoman invasion resulted. At this time, the Turks were ruled by an able family of viziers, the Koprulus, who started reforming the state in order to make the Ottomans a power to contend with once again. As a result, when the Turkish army started to advance westward, the alarm went up all over Europe, with even Louis XIV sending 4000 troops to help the Hapsburgs (and make himself look like a good Christian). In 1664, a much smaller, but better equipped and trained allied army caught and destroyed a Turkish army while it was crossing the Raba River. This was the first major victory of a

Christian army over the Ottomans. However, it encouraged Leopold's allies to feel secure enough to take their troops home, leaving him to face the Turks alone. Instead of continuing the fight, he signed a humiliating peace that damaged his reputation considerably. As a result, the Hungarian nobles under his rule rebelled and called in the Turks to help them.

This triggered the Turks' last major invasion of Europe, climaxing at the siege of Vienna in 1683. A huge Turkish army of possibly 150,000 men, but with no large siege artillery, was faced by only the stout walls of Vienna and a garrison of 11,000 men. The siege lasted two months as the Turks gradually used the old medieval technique of undermining the walls. Just as they were poised to take the city, a relief army from various European states arrived and crushed the Turkish army.

After this, Hapsburg forces and their allies advanced steadily against the Turks, only being interrupted by having to meet French aggression in the West. In 1697, the allied forces demolished another Turkish army at Zenta and watched as the once proud Janissaries murdered their own officers in the rout. The resulting treaty of Karlowitz (1699) gave Austria all of Hungary, Transylvania, and Slavonia. Karlowitz re-established Austria, now also known as Austria-Hungary, as a major European power. From 1700 until the end of World War I in 1918, the Hapsburg Empire would dominate southeastern Europe, while the Ottoman Empire staggered on as the "Sick Man of Europe."

Although the Hapsburg Empire had regained its status as a military and diplomatic power, it still had serious internal problems, namely a powerful nobility ruling over enserfed peasants, a hodge-podge of subject peoples with nothing in common except that they all called Leopold their emperor, and a variety of states that each had their own rights, privileges and governmental institutions. The Hapsburgs dealt with these problems in three ways. First of all, they neutralized the nobles politically by making a deal that let them continue to oppress the peasants as long as they did not interfere in the government. This left the nobles fairly happy while giving the Hapsburgs a free hand to run the state, largely with soldiers and bureaucrats recruited from other parts of Europe. Unfortunately, this also left the empire socially and

economically backward. Second, they tried to unite their empire religiously and culturally by imposing the Catholic faith and promoting the German language throughout their empire. Trying to submerge native cultures, such as that of Bohemia, under Catholicism and German culture mostly caused resentment against Hapsburg rule. Finally, they ruled each principality (Austria, Hungary, Bohemia, etc.) separately with its own customs and institutions. This kept nobles of different provinces from being able to combine in revolts against the Hapsburgs, but it also left the empire fragmented into a number of separate provinces. A large standing army and bureaucracy also held the empire together.

For the next two centuries the Hapsburg Empire would be a major power in Europe. However, it had a number of serious problems that it never adequately solved, being socially and economically backward and fragmented into a large number of provinces and increasingly restless ethnic groups. Together, these problems gradually ate away like a cancer at the Hapsburg Empire, rotting it out from within until there was hardly anything left to hold it together by the twentieth century.

The 2nd Turkish Siege of Vienna (1683)

An overview of how Vienna probably looked in the 1600s

The first siege of Vienna in 1529 was only a temporary setback for the Turks, who remained, especially in the European imagination, the biggest threat to Western civilization and Christianity. Therefore, when the Turks were on the move again in the 1660s, various European rulers rallied to Leopold of Austria's side, even Louis XIV of France sending 4,000 soldiers. In 1664, Austria's general, Raimund Fürst Montecuccoli, caught the Turks foolishly crossing the Raba River into the teeth of his army and finished them off regiment by

regiment before they could amass together on his side of the river.

Unfortunately, Leopold's allies thought this victory ended the war, and went home, leaving Leopold in the lurch. The Turks thought differently, however, and forced Leopold, now without his allies, to buy them off with an annual payment of 200,000 gold florins. This discredited Leopold and made it harder to drum up support the next time the Turks attacked.

In 1678, the tighter control Leopold tried to exert over Hungary upset a number of Hungarian nobles who, led by Emmerich Imre Thököly von Késmark rebelled against Hapsburg rule and called in the Turks. In 1683 this led to another Turkish invasion and the second siege of Vienna.

The Turkish army was said to number between 150,000 and 200,000 men along with assorted camels, elephants, and the vizier's harem. Among them were hordes of Tartar and Magyar cavalry. The Tatars were Turkic-speaking peoples who had been conquered by and probably ethnically mixed with the Mongols. They had several khanates, successor states of the Golden Horde, on Russia's eastern and southern borders. The Khanate of the Crimea was allied with and tributary to the Ottomans and sent forces to help them in 1683. They typically preceded the main army, pillaging and wasting enemy lands in their path. While destructive to the Austrians, this also deprived their Ottoman allies of valuable forage.

Anti-Turkish propaganda, such as the 17th century print below, played up (and exaggerated) the atrocities committed by the Ottomans. Perceived as the primary threat to Christianity, the Turks, were portrayed in the most terrifying terms in the European press, which has heavily distorted the West's view of them specifically and Islam in general ever since. Such propaganda also inspired what was essentially the last of the crusades, the War of the Holy League.

Because of Leopold's poor showing in 1664 there was little response to his call for help this time around. Consequently, he abandoned Vienna, leaving it with a garrison of only 11,000 men commanded by an able and determined officer, Count Ernst Rüdiger von Starhemberg. Before leaving, Leopold's brother-in-law, the Duke of Lorraine burned any houses and buildings outside walls to destroy any cover for Turks approaching the city. Unfortunately, sparks from these fires got inside Vienna and spread across the city, heading toward the arsenal holding 1800 barrels of gunpowder. Luckily, the wind shifted just before the conflagration reached the arsenal, thus saving the city. Meanwhile, through the smoke of this fire, the Viennese could see the smoke of distant villages in flames, signaling the approach of the Ottoman army.

Vienna's fortifications consisted of four layers of defense that the Turks would have to get through in slow succession:

- 1) A banked earthen grade;
- 2) Behind it an escarpment or wall with a palisade on top;
- 3) A Dry moat with blockhouses in it; and
- 4) The main wall reinforced with massive bastions at angles to one another.

The squiggly lines on top represent the Turks' siege trenches that gradually worked their way forward as a prelude to undermining the walls

In addition, the Turks had only brought light and medium artillery, but no heavy siege guns for pounding the city walls. While these were useful for firing over the walls into the city to make life as dangerous and miserable as possible for the inhabitants, the Turks would have to resort the slow and tortuous process of digging a zig-zag pattern of trenches (below) to avoid a direct line of fire from the enemy, undermining the walls, and then collapsing the mines so that

the fortifications above would also collapse, leaving a breach through which they could storm into the city. For this they concentrated on the western side of the city where suburbs still stood and the ground wasn't too marshy for digging mines.

On July 14, while their artillery opened fire on the city they started digging trenches in a snaking pattern to approach the walls, quickly closing the gap between their camp and the city from 400 to 200 meters. By July 17 they had the city surrounded by land and the river (with two bridges). On July 23 they exploded their first mines leading to a continuous series of assaults and counterassaults. On August 3rd, the Turks broke through part of the outer escarpment, triggering a series of furious battles until the defenders had to abandon the moat. Now, all that stood between the Turks and the city was the last, though most formidable, line of fortifications.

Life inside the city during the siege was, in many ways, typical of sieges throughout history. The most immediate danger was cannonballs setting buildings on fire. This led to an order to strip the roofs of all buildings within range of the Turkish guns. The roof timbers were then used for two things: repairing damage to the fortifications, and soaking them in pitch and lighting them in the moat during night attacks. As a result, by the end of the siege, Vienna presented a strange spectacle of roofless buildings.

Another hazard came from bombs exploding and shells shattering cobblestones, which sent potentially lethal fragments of rock flying in every direction. Therefore, the Viennese stripped their streets of cobblestones, which were also used for repairing fortifications or throwing down onto the attacking Turks.

Housing was an acute problem for homeless refugees who had flocked into the city to flee the approaching invasion. By the same token, a number of people, especially rich ones, had fled the city, so the refugees were put into their now empty homes.

Sanitation, in particular, the disposal of waste and the bodies of dead people and horses was an even more serious problem. Being summer, the Danube was too low to wash away waste. Therefore a town ordinance was issued to remove all dirt, rubbish, blood, and animal waste from the streets, since it was believed that an epidemic was caused by filthy streets "*in which soldiers and poor sick people lie bleeding over whom other people have to step.*" In addition, the large pits they dug for the waste soon filled up, triggering a dysentery epidemic that probably killed more of the city's inhabitants than the Turks did. Similarly, cemeteries soon ran out of room, forcing the Viennese to resort to mass burial pits.

Hospital and medical facilities were also inadequate, despite the bishop's efforts to turn the monasteries into hospitals. In particular, a lack of straw forced the sick and wounded to lie on the bare floor or ground. By mid August 30 people were dying each day; by late August it was double that. Not surprisingly, by the end of the siege, a poisonous stench permeated the city.

As in all sieges, the food supply was among the most acute problems. In the siege's first weeks, people ate well, not knowing how long the siege would last and therefore how much they should ration. In addition fresh vegetables and meat had to be quickly consumed before they spoiled. For whatever remained, mainly bread, prices skyrocketed.

Also, as was typical for sieges, bakers were a source of trouble, partly for cutting the quality of their bread with non-nutrients to expand their stock, partly for raising prices, and partly for improper baking since there wasn't enough fuel or ovens for baking enough bread for the crowded city. As a result, each baker had to put a mark on his bread for quality inspection, and sell it for a reasonable price. However, despite strict price controls, prices continued to skyrocket.

In a desperate search for food, some women sneaked out of the city to trade whatever goods or services they could to the Turks for food. In

response, Starhemberg, fearing someone might betray the city for food, erected three gallows in a prominent place to stop this activity.

Another aspect of enduring siege was the psychological effect of constant bombardment. Surprisingly, rather than going crazy, people more or less got used to it. For example, at the great Church of St. Stephen, a cannonball crashed through the roof during mass and landed in one of the organ's pipes. Soon after clearing the building, the congregation returned, figuring they were as safe there as anywhere else from random cannonballs hitting them.

The siege grinds on. By August, the siege had developed into an exhausting pattern of the Turks inching their trenches forward, setting off mines, and assaulting the breach, then the Austrians to driving them back and repairing the breaches. The pattern would then start all over again. All this time, the Ottoman commander, Kara Mustapha, was growing increasingly enraged at the slowness of his army's progress as this tiny garrison inflicted mounting casualties on the Turks in this grim slugging match. Still, the Turks were making progress and methodically demolishing Vienna's fortifications.

By September, they were working on the main walls against a garrison reduced by casualties and disease to around 4,000 men who were totally worn out by seven weeks of relentless fighting and wall repairs. Starhemberg did enlist 5000 civilians for guard duty, but the exhausted regulars still had to face the much more hazardous combat and repair duties. Luckily for the defenders, the Turks were concentrating only on the western walls.

Everyday, Starhemberg would mount the tower of St. Stephen, scanning the horizon for any signs of the relief army he had been promised. Indeed, a relief army of 60,000 Poles, Germans, Austrians, and other nationalities under the Polish king, Jan Sobieski, had been assembled and sent signals and messengers to the beleaguered city that they were on their way.

On September 10th, an advance party of this relief army, twenty soldiers, was captured. After seeing all 19 of his comrades killed, the twentieth soldier talked, convincing Kara Mustapha that an army of 100,000 Christians was on its way. So the clock was ticking down.

Two days later, final preparations were in place to blow the mines that would demolish the remaining fortifications and open the way for the final assault. Just then, the Christian army broke through a heavily wooded area to the west and attacked the Turks. The Turks, already weakened by the siege, held for a while, but eventually their line disintegrated into a rout and the city was saved.

Sobieski's message announcing the victory to the rest of Europe was short and to the point: "We came. We saw. God conquered."

Charge of the Polish winged hussars at Vienna (1683). When they charged the winged structures on their backs created an eerie whirring noise designed to terrify their enemies. The Hussars suffered such heavy losses from Janissary gunfire in this battle that they were disbanded soon afterwards, marking the final end of shock cavalry in European history.

A Short History of Pastries

After the siege of Vienna, Viennese bakers celebrated their victory by concocting a new crescent-shaped roll, the croissant, to mock the crescent moon on the Turkish flag. Thus two sieges of Vienna (in 1529 and 1683) combined to give us coffee and croissants, a good tasting part of a nutritious (if fictional) breakfast.

The history of pastries didn't start there, however. In the middle ages, "waffles of forgiveness" were sold outside of churches. In Paris, certainly one of the spiritual homes of

pastries, bakers weren't supposed to wear pants six days a week in order to keep them on the job, although it was probably more to ensure the supply of bread rather than bon bons.

When the Spanish first encountered chocolate in the New World, they kept it so secret that when Dutch pirates captured a Spanish ship, they dumped its cargo of cacao beans, thinking they were sheep droppings.

The War of the Holy League (1683-99)

The victory at Vienna led to the Holy League, an alliance of Austria, the Pope, Poland, Venice, and even Russia, which agreed to attack the Turks if Poland would let it keep the disputed city of Kiev. This was the last of the great popular crusades, its popularity fed by mass production of pamphlets and pictures showing Christian victories and promising salvation for recruits fighting the infidel. This drew soldiers from all over Europe, but especially Germany and Bohemia.

The wrecking of the Acropolis. In 1685, the ceremonial entrance to Athens' Acropolis, the Propylaea, which at that time was being used to store gunpowder, blew up when hit by lightning. Therefore, the Turks, needing a new arsenal, moved their gunpowder into the Parthenon. In 1687, the Venetians were besieging Athens when one of their shells hit, you guessed it, the Parthenon, detonating its store of gunpowder. The resulting explosion was responsible for most of the damage the Parthenon has sustained in its long history.

Hapsburg triumph. Meanwhile, the Holy League's forces slowly moved up the Danube, reducing Turkish fortresses one by one. However, in 1688, Louis XIV took advantage of Austria's preoccupation in the East and invaded Germany, starting the War of the League of Augsburg (1688-97). As a result, the Turks were able to advance back through Hungary and Transylvania until the Holy League was free to take them on again.

On September 9, 1697 the Imperial Army led by Prince Eugène caught an Ottoman army, led by Sultan Mustafa II, as it was crossing the Tisza

River on a pontoon bridge near Zenta. The Turks suffered a devastating defeat, 25,000 of them supposedly being killed or drowned, compared to only 430 dead and 1,600 wounded Austrian soldiers. Even the Janissaries, desperate to get away, killed their own officers right under the eyes of the Sultan and Grand Vizier. Making matters worse, the Sultan's vast treasure was also captured.

Mecheln; Duke of Lorraine and Bar; Grand Duke of Tuscany.”

[Back to flowchart](#)

Two years later (1699) the Treaty of Karlowitz was signed, giving Hungary and Transylvania to Austria. With the renewal of war in the West by Louis XIV in 1700, the Hungarians raised the standard of revolt, which didn't collapse until the end of the war with France in 1713. In that year, the three thrones of Austria, Hungary, and Transylvania were made hereditary, signaling the consolidation of the more substantial Hapsburg Empire of Austria-Hungary. While the Hapsburgs would continue to hold the crown of the Holy Roman Empire until Napoleon Bonaparte declared it defunct in 1806, their real balance of power had shifted eastward.

The nightmarish political and ethnic complexity of Austria's empire can be seen in the full title and coat of arms of the Hapsburg ruler, Joseph II (1780-90):

“Roman Emperor, Apostolic King of Hungary, Bohemia, Dalmatia, Croatia, Slavonia, Galicia, Lodomeria, Archduke of Austria, Duke of Burgundy, of Styria, of Carinthia, and of Carniola, Grand Prince of Transylvania, Margrave of Moravia, Duke of Brabant, of Limburg, of Luxemburg, of Geldern, of Wurtemberg, of Upper and Lower Silesia, of Milan, of Mantua, of Parma, of Piacenza, of Guastalla, of Auschwitz and Zator; Prince of Swabia, Prince-Count of Habsburg, Flanders, the Tyrol, of Hennegau, of Kyburg, of Gorz and Gradisca, Margrave of the Holy Roman Empire, of Burgau, of Upper and Lower Lusatia, Count of Namur, Lord of the Windisch March and of

BRANDENBURG-PRUSSIA & THE ROOTS OF MODERN GERMANY (1640-88)

"...men under 60 years of age shall not be admitted to monasteries...Priests & curates (if not ordained), & the canons of religious establishments, shall marry...Every male shall be allowed to marry two wives; & each & every male is earnestly reminded, & shall often be warned from the pulpit, to so comport himself in this matter."—Declaration of the German Diet, 1650

As badly as the Thirty Years War had treated Hapsburg Austria, it was much worse for the German states comprising the Holy Roman Empire. Some estimates of population loss in the war go as high as 35-40%, with material damage at an equally frightening level. However, human beings are a resilient species in the face of such adversity, and recovery was soon underway. Travelers in Germany a few years after the war noted a marked absence of men of military age, but an unusually high number of children. By 1700, Germany's population was back to its pre-war level of 20,000,000. Similar resilience was shown by the tiny state of Brandenburg-Prussia in northern Germany. In 1648, no one looking at this poor little state devastated by war would have believed it was destined one day to unite all of Germany and become a major world power.

Brandenburg had lived under the rule of the Hohenzollern dynasty since 1411 when Frederick of Hohenzollern had purchased the territory and one of the seven electoral votes of the empire along with it. In 1618, the elector, as the ruler of Brandenburg was known, also got control of Prussia some 100 miles to the east, holding it as a vassal of the king of Poland. Brandenburg especially suffered during the Thirty Years War, since it was caught between the Catholic imperialists to the south and Swedes to the north, not to mention its own rapacious mercenaries. This was the situation when Frederick William, known as the Great Elector, took power in 1640.

Frederick William found an imposing array of problems that fell into three basic categories: geographic, military/diplomatic, and economic. Frederick William's main geographic problem was that the territories of Brandenburg and Prussia were separated by 100 miles of Polish territory, making it very difficult to control and administer. Economically, Brandenburg was a poor country with few resources and a sandy soil that earned it the nickname "the sandbox of Germany". There were several factors aggravating the military and

diplomatic situation. Worst of all was the devastation suffered at the hands of the Imperialists, Swedes, and Brandenburg's own troops. An estimated 60% of population was lost from the war, falling from 1.5 million to 0.6 million. Not only that, but Swedish troops were still on Brandenburg's soil in 1640, with other powerful threatening neighbors, such as Poland to the east and France to the west. To meet these threats, Frederick William's army consisted mainly of unruly mercenaries as likely to plunder his lands as defend them. And he also faced a powerful class of nobles known as *junkers* who were a constant obstruction to the government.

Frederick William figured that, above all else, he needed to tackle his military and diplomatic problems by building a good army to protect himself and his realm. The first step was to use what few reliable troops he had in order to destroy his old army of worthless mercenaries. One by one, he eliminated his old regiments until he had only an army of 2500 men, but it was a loyal core upon which to build. Through diligence and hard work, Frederick William built an excellent army of some 8000 men by 1648. This was enough to give him a voice in the treaty talks at Westphalia. His main goal was to get Pomerania which, although legally Brandenburg's, was occupied by Swedish troops. He had to settle for half of Pomerania, but that was more than he could have expected eight years earlier, and it did give him a coastline on the Baltic Sea.

Inspired by his success, Frederick William kept building up his army and bureaucracy. For an officer corps and civil officials, he turned to the junkers. Like his contemporary, Leopold I of Austria, he let the nobles maintain their dominance over the serfs. But unlike Leopold, who did this to keep the nobles out of the government, Frederick William *required* service to the state in return for those privileges. The junkers were expected to serve in the army as officers or as a highly efficient civil service that could provide better support for the army in the way of tax collection and supplies. They received fancy uniforms and excellent training, and soon had developed a high morale and pride in themselves as *the* officer class of Brandenburg-Prussia. That tradition of a proud Prussian officer class as the backbone of the state would continue all the way down to the twentieth century. As a result of this policy, Brandenburg-Prussia was the only state in Europe where the government successfully allied with the nobles and used them effectively in government service.

For recruits, Frederick William and his successors started to rely increasingly on peasant draftees rather instead of undependable and expensive foreign mercenaries. Such soldiers were much cheaper than mercenaries and much less prone to looting, although not as efficient. During peacetime, they could be kept in training for a few months each year while letting them farm and be productive the rest of the time. By the end of his reign, Frederick William was able to field an army of 45,000 men, with a smaller, but still sizable standing peacetime army.

In addition to defense, the army also helped Frederick William increase his power internally, since he could use it to demand taxes and enforce his policies. With those taxes, he could increase his army, which further increased his authority, and so on. As a result, Frederick William laid the firm foundations for absolutism in Brandenburg-Prussia.

As far as Brandenburg-Prussia's divided geography was concerned, Frederick William developed a postal system, which better tied together his scattered realm and also generated more revenue for the government. Even so, Brandenburg-Prussia was still a small fish in a big pond, and a turbulent pond at that. The later 1600's were hardly more peaceful than the early 1600's, with an aggressive Sweden to the north and Louis XIV's France to the west keeping Europe's armies constantly on the march. Thus, Brandenburg-Prussia's geography and revived army both forced and allowed Frederick William to pursue a foreign policy that was, in a word, opportunistic.

Throughout his reign he skillfully switched sides whenever convenient and sold his army's services to the highest bidder or most useful allies. For example, in the fighting between Louis XIV and the Dutch Republic, he switched sides three times. Likewise, in the Northern War between Poland and Sweden (1655-60), Frederick William at first was neutral, then on Sweden's side, and finally on Poland's side in return for recognition of his title to Prussia being totally independent of his overlord, Poland. This independent title gave Frederick William special status among German princes, who in theory were still under the power of the Holy Roman Emperor. In fairness to Frederick-William, it should be said that switching sides so often was typical of European diplomacy at this time. Although his policies gained him some land and the independent title to Prussia, his major accomplishment was holding his original realm together in the midst of such powerful neighbors while rebuilding its prosperity.

At the same time, Frederick William was every bit as talented in economic matters as he was in military and diplomatic affairs. He did several things to restore Brandenburg-Prussia's prosperity. For one thing, he took an active interest in the development and use of new agricultural strains and techniques that would allow crops to thrive in Brandenburg's sandy soils. Since the vast majority of the populace was engaged in agriculture, this was especially significant. Also, Frederick William encouraged immigration to repopulate his realm. Louis XIV's revocation of the Edict of Nantes in 1685 (which took religious freedom from the French Huguenots) certainly helped Frederick William here, since some 20,000 Huguenots found their way to new homes in Brandenburg-Prussia. This was largely with the help of the Great Elector, who supplied the Huguenots with traveling money, guides, land, tax exemption for six years, and various other privileges. Thus, France's loss was Brandenburg-Prussia's gain, since the Huguenots were some of the hardest working and most highly skilled people in Europe. Finally, the government controlled monopolies on the production and sale of such commodities as salt and silk. The efficient management of these monopolies raised important funds for the government.

Frederick William also used the army during peacetime to develop public works projects. For example, the army built a canal connecting Berlin, the capital, to the Oder River, thus increasing trade and tax revenues. Much of that extra revenue surely went back into the army. But at least it was partially able to pay for itself in peacetime. This also kept the army from causing trouble during times of peace and idleness.

By Frederick-William's death in 1688, Brandenburg-Prussia was in better shape than before the Thirty Years War. Its population was back up to pre-war levels, while its tax revenues had increased from 59,000 thalers in the 1640's to 1,533,000 thalers in 1689, over twenty-five times its original revenue. Its army provided more security than ever before while also giving Brandenburg-Prussia an unprecedented amount of international prestige and respect. However, this was only the beginning. Frederick William's reforms set the stage for two centuries of steady growth and expansion that would culminate in the unification of Germany and its rise to the status of a world power in the nineteenth and twentieth centuries.

Background to the Great Elector's Reign

Henry the Fowler originally established Brandenburg in the 900's as the Northern March (military frontier) of the Saxons on the Elbe River against the Slavs to the east. For centuries it changed hands between Germans and Slavs before the German element prevailed.

Prussia came into the Hohenzollern fold in 1618 just as the Thirty Years War was starting. However, it was held as a vassal of Poland and was outside the jurisdiction of the Holy Roman Empire. Besides Brandenburg and Prussia, the Hohenzollerns also ruled the tiny principalities of Cleve, Mark, and Regensburg scattered across the western part of Germany.

Frederick-William's early life was no picnic. Despite being the ruler of a principality, his father couldn't afford a proper baptism for several months. (Because of the high infant mortality rates, babies were baptized as soon as possible after birth to ensure they went to heaven if they suddenly died.) Even worse, his family had to flee Berlin when he was eleven years old.

Three years later, Frederick-William, whose great grandfather was William of Orange, fled to the Netherlands. At age 18, he had to return home to spend two years of unhappy inactivity while his father was under the influence of the Austrian minister, Schwarzenburg. In 1640, he inherited control of Brandenburg-Prussia, or what was left of it.

The next eight years were the worst period of the Thirty Years War, especially for Brandenburg, which lay in the path of the big aggressive power of the day, Sweden. Frederick-William's own army was so bad that one of his colonels threatened to burn the town he was defending if

it didn't pay off his men. Another regiment of supposedly 2200 men in fact had only 100. By the end of the war in 1648, Brandenburg had lost roughly 60% of its population, but Frederick-William had rebuilt a reliable army that secured his borders and earned him a place at the peace talks in Westphalia.

Frederick-William's Army

The chicken or the egg? So what came first: Frederick-William's army or the money to build his army? In this case it was the money. In 1653 the Brandenburg estates (assembly of towns and nobles), probably concerned about their country's security, granted Frederick-William taxes for building his army six years in advance in return for the right to run their own estates and appoint their own local pastors and police. Normally, taxes were only granted one year at a time, which kept rulers somewhat dependent on their estates. However, after six years of living without having to rely on the estates, Frederick-William had built up enough of an army that he had the leverage to demand taxes from a position of power.

Adding to his leverage was the fact that North German nobles (AKA junkers) were relatively poor compared to nobles in other parts of Europe and needed the employment from the state.

Fancy military uniforms were such a special mark of status in the 1600s that men's civilian fashions, in particular hats and boots, copied them.

Prussia's peasant recruits. Frederick-William started developing a canton system, where each canton (district) was responsible for supplying one regiment for the army. In fact there were enough recruits for two regiments, but the extras were kept as a reserve to replace any losses, thus

keeping each regiment up to full strength. By 1733, this system was fully developed, so that Prussia was able to keep a large standing army (still mainly of professional mercenaries) along with substantial trained reserves at a much lower cost than other states that relied solely on mercenaries.

This system especially would prove its worth in the Seven Years War (1756-63) when Prussia's ruler, Frederick the Great, would face vastly superior forces from Austria and Russia, even suffer a number of defeats, and yet constantly bounce back with new armies to surprise and defeat his enemies. To the Russians and Austrians, it seemed as if Frederick was producing new armies from the soil itself. In a sense he was, replenishing his ranks with trained peasants who normally worked the soil.

The Northern War (1655-60)

The Northern War was typical of the problems Frederick-William faced in the late 1600's. In a sense, it started with Sweden's Queen Christina (below) who had succeeded her father, Gustavus Adolphus, after his death at the Battle of Lutzen in 1632. At the time she was a young girl, so Gustavus' minister, Axel Oxenstierna had largely guided Sweden through the rest of the Thirty Years War.

Christina was sickened by the violence of the war and wanted to end it as soon as possible. She was also one of the more unique personalities of the age. Refusing to be limited to the normally constricted roles of women then, Christina wore men's clothing, rode horses in the straddling (not lady-like sidesaddle) position, went hunting, swore like a sailor, and seemed to do anything else calculated to shock her contemporaries.

In 1654 she shocked Europe in a whole new way by abdicating her throne, converting to

Catholicism, and moving to Rome to live as a nun. Her successor was Charles X, another in the line of warlike Swedish kings in the 1600s. One of the things pushing him to war was the end of the Thirty Years War, because, in an age of mercenaries, peacetime was often anything but peaceful with a bunch of unemployed professional killers on the loose in society. The obvious solution to such a problem was to start another war, which is what Charles did.

For his victim, he settled on Poland where Sweden's Vasa Dynasty had claims to the throne. In addition, success in such a venture would give Charles control of the Baltic. So in 1655 the Swedish army landed in Pomerania and marched across Brandenburg to invade Poland.

At this point, Frederick-William had three options:

- 1) Stay Neutral;
- 2) Join Sweden to throw off Polish over lordship of Prussia; or
- 3) Join Poland and fulfill his duty as a loyal vassal and try to get W. Pomerania

He did all three, although not at the same time.

At first, he stayed neutral, since his peacetime army at the time was down to 4,000 men. Therefore, he had to let the Swedes, who landed in West Pomerania march across Brandenburg to get to Poland. This bought him time to build up his army, which by war's end, would number 27,000 men and win respect for his neutrality.

Meanwhile, Charles had marched victoriously across Poland, winning recognition as its king. However, the Swedes' savage treatment of the Poles led to a revolt and Charles was forced back to the Prussian border. Desperate for help, he bought Frederick-William's support. Together, their combined army of 18,000 took on and defeated a Polish army of 70,000 poorly armed and disciplined men in a three-day battle. However, disease struck their army and they had to retreat again, with Frederick-William forcing Charles to recognize him as the sole ruler of Prussia in return for his continued support.

As in the Thirty Years War, much of the fighting in the Northern War consisted of skirmishes and ambushes, such as this Polish ambush of a Swedish supply convoy. These tactics especially suited the Poles whose light cavalry, many of them Cossacks, were very mobile and adapted to this sort of warfare.

Then, in 1657 the emperor, Ferdinand III, died. Frederick-William, as one of the electors, quickly became involved in all sorts of intrigues and deals to elect a new emperor. Finally, he cut a deal with the Hapsburgs and their Polish Catholic ally to vote for Leopold as emperor and switch sides in the war in return for being recognized as the independent ruler of Prussia.

By 1660, the Poles and Frederick-William had slowly driven back the Swedes until pressure from France and the Dutch along with Charles' death brought about peace and recognition of Frederick-William as the independent ruler of Prussia, a status no other German ruler outside of the Austrian Hapsburgs could claim.

Poland's Liberum Veto and Great Deluge
Poland, a large and powerful state in the 1500s, started coming apart in the 1600s. Much of its weakness came from a weak central government controlled by powerful nobles and a law known as the Liberum Veto. According to this, all laws had to be passed by the *Sejm* (legislature) unanimously. This may have come from an old Slavic practice where villages would resolve all matters by consensus.

Maybe this worked on the level of a village, but using it to run a nation was entirely impractical, especially when one considers the second part of the Liberum Veto. This stipulated that, even after passing several bills unanimously, if there was only one dissenting vote on a succeeding

bill, not only did that bill get thrown out, but all laws previously passed by that session of the Polish Diet were also thrown out and the Diet was dismissed for two years. Not surprisingly, this proved a useful tool for foreign powers or disruptive elements within Poland to paralyze its government by bribing just one member of the Sejm to exercise his veto.

As a result, the period of Polish history after 1650 is typically referred to as the Great Deluge, since Poland, already hobbled by the Liberum Veto, faced wars against Sweden, Russia, and the Turks, as well as a massive rebellion by the Cossacks in the Ukraine. These wars along with its weak government led to Poland's steady decline until it was finally partitioned by its neighbors in the late 1700s and briefly disappeared altogether from Europe's political maps.

The Polish Hussars

The pride of the Polish army was its heavy cavalry, known as Hussars, whose shock tactics proved surprisingly effective against pike formations and musketeers. Before entering the Thirty Years War, Gustavus Adolphus, who had fought for years in Poland against Polish hussars, adopted their tactics, and briefly revived the use of shock cavalry in Western Europe.

"We saw it.... the hussars let loose their horses. God, what power! They ran through the smoke and the sound was like that of a thousand blacksmiths beating with a thousand hammers. We saw it...Jezus Maria! The elite's lances bent forward like stalks of rye, driven by a great storm, bent on glory! The fire of the guns before them glitters! They rush on to the Swedes! They crash into the Swedish riters.... Overwhelm them! They crash into the second regiment - Overwhelmed! Resistance collapses, dissolves, they move forward as easily as if they were parading on a grand boulevard. They sliced without effort through the whole army already. Next target: the regiment of horse guards, where stands the Swede King Carol. And the guard already wavers!" description from Deluge Henry Sienkiewicz

THE GEOGRAPHY AND PATTERNS OF RUSSIAN HISTORY

The last and easternmost state to assume a place in European culture and diplomacy was Russia. Three aspects of Russia's geography have had a major impact on its history. First of all, its location on a high northern latitude and far inland gave it a cold and dry climate. That, combined with large areas of poor or mediocre soils, made it a cold dry steppe in which it is difficult to survive, let alone prosper. Famine has affected Russia on an average of one year out of three throughout its history.

Second, Russia lies on the vast Eurasian Steppe with no formidable natural barriers, which has invited a number of invasions with tragic results. In its early history, the main threat would come from the nomadic tribes to the east, making Russia a battleground between nomads and farmers. Only more recently have Russia's neighbors to the west been the more serious threat, as seen by the loss of an estimated 27,000,000 people in World War II. Ironically, Russia's harsh climate has saved it from invasion more than once. Napoleon and Hitler both found out the power of "General Winter" when they made the mistake of trying to conquer this vast northern giant.

Finally, Russia's inland location to the north and east of Europe has left it largely isolated from the mainstream of developments in Europe. Altogether, Russia's geographic features have made it a harsh land facing constant invasions. As a result, Russians have historically been torn between needing and wanting foreign ideas with which they could better compete and survive on the one hand and a suspicion of foreigners bred by the continual threat of invasions they have faced on the other.

This love-hate relationship with foreign ideas has created recurring stress throughout Russian history all the way to the present. In its early history, one can see three major stages of development where it has taken place. The first of these was when the first Russian state, centered on Kiev, was confronted with Byzantine influence from the south. The Cyrillic alphabet, Russian Orthodox Christianity, and Russian art and architecture all bear the distinctive marks of Byzantium. The next major influence came from the Mongols who conquered Russia in the 1200's and introduced the harsh absolutist strain that became a hallmark of later Russian government. The last phase, highlighted by the reigns of Ivan IV and Peter I, witnessed growing influence from Western Europe. Ivan IV's reign saw the first attempts to gain access to the West for its technology, the use of Western

artillery in the conquest of two Mongol khanates, and the attempts to replace the traditional Russian nobility with a new nobility of service. While his efforts had only limited success, they helped set the stage for the more widespread and concerted efforts of Peter I to westernize Russia. Despite the conservative backlash that followed Peter's reign, Russia from that time on was an integral part of Europe and European civilization.

Russia's Physical Environment

A Russian joke about Siberia and its primitive conditions:

Q: What's the only moving part on a Siberian toilet?

A: A stick to drive off the wolves.

Steppe and forest. Steppe (above) is generally defined as dry grassland receiving between 10-20 inches of rain per year. The Eurasian steppe extends all the way from the Pacific into Central Europe, only slightly interrupted by the very old and worn down Ural Mountains. Steppe grasses could get so tall that sometimes only the head of a man on a horse would be visible. However, that only describes the southern part of Russia. The northern part was more forested and, especially after the Mongols came in the 1200s, Russians became more a forest people, the woods providing them logs for homes, firewood for warmth, moss to chink cabins, bark for shoes, and meat, honey, and berries for food.

Russians were also a communal people and Russia an empire of lonely villages with a few cabins and an onion-domed church. Most cabins consisted of one room without a chimney leading to everyone and everything being constantly black from soot. As a result, public baths were a common institution in almost every Russian village where men and women washed together. After the bath, they would step outside, even in winter, to let the wind dry them off.

The round of seasons. Russia is especially known for its winters, which would last 160 days, alternating between bleak grayness, blinding snowstorms, and even more blinding sunlight reflected off the snow. Furs worn for warmth also carried lice (which spread typhus) and fleas (which spread plague). Spring brought the thaw...and mud. But May 1st was still a day of celebration to welcome the warm weather. However, spring's moderation would quickly give way to summer's long, hot, dust-choked days and very short nights. The heat and humidity of summer also brought rats and insects, such as swarms of mosquitoes in low-lying areas, which means most of Russia since it is so flat. In September came the rains and with them more mud, soon followed by frost, ice, and once again winter.

Travel in winter by sleigh over hard ice and snow was often preferred to travel in other seasons when roads were muddy or dusty and full of potholes.

Siberia. As extreme as the climate in European Russia (basically west of the Ural mountains) may seem, it pales in comparison with Siberia, which is further removed from the moderating effects of large bodies of water than any other landmass on earth. That is if one does not count the Arctic Ocean, which until the twenty-first century has mostly been a frozen icecap.

Temperatures tend to get colder the farther east one goes. Outside of a few bases in Antarctica the Sakha district of Siberia is probably the coldest inhabited region on earth, with permafrost reaching down 1,493 meters (4,898 ft). The town of Oymyakon has recorded temperatures as low as -96.2° F. While mainly noted for its cold climate, parts of Siberia reach 100°F in the summer, also a result of not having the moderating effects of large bodies of water.

When temperatures fall below a certain point, nothing seems to work. Cars and trucks are kept running 24 hours a day to keep the engine blocs from freezing. Windows need to be triple paned, and car windows double paned.

Construction of roads, railroads, and buildings is especially complicated by the permafrost, which thaws into a virtual mush down to certain depths in the summer. Therefore, foundations must be especially deep to keep structures from settling and sinking. In some cases, steam hoses are used in conjunction with pile drivers to melt the permafrost to depths of fifty feet. Once the permafrost re-freezes, it locks the foundations permanently into place. Given such huge challenges, the construction of something like the Trans-Siberian Railroad stands as a marvel of Russian perseverance.

THE EARLY HISTORY OF RUSSIA TO 1725

Early history. The earliest written references to inhabitants in Russia were the Scythians, nomadic horsemen who inhabited the southern steppes in the time of the classical Greeks. Russia's grassy plains provided ideal grazing for these nomads' sheep and horses. Some time after 500 A.D., various Slavic tribes, ancestors of most of today's Russians, moved in and settled down in Russia. Then, around 900 A.D., Vikings, known as the Rus, came in and united the Slavs under a state centered around Kiev.

The Rus used Kiev and other Russian cities as bases from which to raid their more civilized neighbors to the south, in particular the Byzantines. The first such raids were successful in forcing tribute from the emperors in Constantinople in order to make the Rus go home. Later raids were met by the dreaded Greek fire, which set the Rus' navy and the very sea itself ablaze. In the wake of Greek fire came Byzantine missionaries, who converted the Rus and their Slavic subjects to Greek Orthodox Christianity. Byzantine civilization has had a profound impact on Russian culture. Many Russians today still cling to the Orthodox faith in spite of over seventy years of Communist disapproval. The Cyrillic alphabet and the onion domes that grace the tops of the Kremlin also bear solid testimony of Byzantine influence on Russia to this day.

Russian civilization and the Kievan state flourished until 1223, when the most devastating wave of nomadic invaders in history arrived: the Mongols. In 1223 C.E. at the Kalka River, the Russian princes were overwhelmed by a small Mongol army whose numbers were exaggerated by panic and confusion to some 150,000 men. Europe itself was only spared Asia's fate by luck rather than the prowess of its armies. Upon Chinghis Khan's death his far-flung hordes returned to the Mongol homeland to elect a new khan. However, the Mongols returned to Russia in 1237 to finish its conquest. They even struck into Poland and Hungary, giving Europe a taste of things likely to come. Amazingly, fate intervened again when Chinghis Khan's successor died. Thus Europe was spared a second time, and the incredible energy that had sent the Mongols to the corners of the known world started to fizzle out.

However, Russia remained the western frontier of Mongol power.

Mongol rule was exercised indirectly through whichever Russian princes were most willing and able to carry out the will of their masters. This meant doing things in the rough and brutal Mongol way, so that after two centuries of Mongol rule, much of the Mongol character and way of running a state had rubbed off on their Russian vassals. The Mongols' expectation of blind obedience to authority and the use of such things as a secret police to enforce their will and inspire terror, a postal relay rider system for better communications, and regular censuses and taxation became a major part of the Russian state that would later evolve.

Muscovy. The most successful of the Russian vassals to adapt Mongol ruling methods were the princes of Muscovy (Moscow) who earned the sole right to collect taxes and dispense justice for the Mongols, while increasingly resembling their Mongol masters in their ruling and military techniques. Eventually, the Muscovite princes turned against their Mongol masters and ended their rule in 1390. It was around Moscow that the modern state of Russia would form.

Mongol rule was gone, but the Mongol terror was not. Nearly every year, the horsemen of various neighboring khanates would ride in to spread a wide swathe of death and destruction, taking thousands of Russian prisoners to the slave markets back home. These raids would depopulate whole regions of Russia. Even Moscow was sacked by the Mongols five different times between 1390 and 1571. While destabilizing Russian society, these raids also forced the Muscovite princes to tighten their grip on society in order to provide better defense. Muscovite absolutism grew even stronger when the metropolitan, or patriarch, of the Russian Orthodox Church moved to Moscow, giving it claim to the title of "the third Rome" after Constantinople and Rome itself. Likewise, Muscovite rulers laid similar claim to the title of tsars (Caesars).

The first truly memorable tsar was Ivan IV, known as "the Terrible" (1533-84). Ivan's reign saw four momentous developments, all of which can be seen as growing efforts to bring in influence from Western Europe. The first, the destruction of the neighboring khanates of Kazan and Astrakhan to

the south and east, was made possible by the use of European artillery. Although the Mongols of the Crimea still remained to carry out their depredations, destroying these other two khanates did relieve the Russian people of some suffering from nomadic raids. It also opened the way for the rapid expansion of the Russians eastward across Siberia to the Pacific in much the same way the United States would spread rapidly westward to the same ocean in the 1800's.

Second was Ivan's long but unsuccessful war against Poland and Sweden to conquer Livonia and gain closer access to Western Europe. Compounding this failure was the third development, the Orthodox Church's growing fear of the Roman Catholic Church. Causing this was increased missionary activity by the Jesuits in the Ukraine and eastern Baltic. Using Western scholarship in debates with the less educated Orthodox clergy, they were able to convert growing numbers of people in these regions. Naturally, the Orthodox clergy saw this as an especially serious threat to their religion and became the most ardent opponents of contact with the West.

Finally there was Ivan's fight against the *boyars*, the powerful Russian nobles. Blaming them for the death of his beloved wife, he launched a concerted campaign against them by setting up the *Oprichnina*, or state within a state, where Muscovy was split between the traditional state and his own *Oprichnina*. Ivan then began an eight-year reign of terror (1564-72) against anyone he suspected of disloyalty. He also tried to replace the boyars with a new nobility of service that would be more subservient to the crown. Since Russia's economy was still quite backward, the tsar had to pay this service nobility with land worked by peasants. Consequently, many peasants fled to the freer lands in Siberia, now opened for settlement by Ivan's wars. The government reacted with a series of laws that tied the free peasants to the soil and made them serfs.

The "Time of Troubles". Ivan's reforms and purges made his reign a turbulent and costly one. Also, Ivan's accidental slaying of his most able son in a fit of passion left the throne to the feebleminded Feodor, who liked to spend most of his time praying and ringing church bells. The reins of government thus fell to the boyar, Boris Gudonov, who

succeeded Feodor as tsar in 1598. At this point, everything in Russia seemed to go wrong at once. The Boyars resisted his attempts to increase royal power. The Orthodox Church thwarted Boris' early attempts to bring Western European knowledge and culture to Russia. And, worst of all, in 1601 a horrible drought and famine killed millions of peasants who revolted out of desperation and the belief that the famine was the tsar's fault. The rebels got help from the Poles, who supported a supposed son of Ivan IV as tsar. Boris successfully defended his realm until, right on the verge of victory, he suddenly died, capping off a remarkably unlucky reign. The Poles had little better luck in holding the throne, their candidate being assassinated and replaced by another boyar. More peasant revolts and another Polish invasion, which took Moscow, tore Russia further apart. Finally, the Church managed to rally the people, drive out the Poles, and set up a stable government. A national assembly called the *Zemsky Sobor* set up a new dynasty, the Romanovs. However, the boyars were as independent and troublesome as ever while increasing their hold on the serfs below. The Church blocked any progressive reforms that it saw as irreligious even making it illegal to play chess or gaze at the new moon. This was the condition of Russia when its most famous zar, Peter the Great, took the throne in 1682.

Peter I (1682-1725) is one of the most interesting characters in Russian history. An enormous man (6'8" tall) with incredible physical strength, he had a strong drive and will to match his physical stature. From an early age, Peter was fascinated with anything from Western Europe, especially technology. He was an amateur clockmaker and dentist (to the dismay of anyone in court with a toothache), and especially loved ships. His early exposure to western ways made him realize how backward Russia was compared to the rest of Europe. Therefore, he was determined that Russia should modernize, which meant it must westernize.

The first step was the Great Embassy, a grand tour of Europe where Peter traveled in disguise so he could experience its culture and technology more freely. The huge tsar's identity was the worst kept secret in Europe, but he did learn about such things as Prussian artillery and Dutch and English shipbuilding first-hand instead of from a distance. In their wake, Peter and his wild entourage left a

trail of ransacked houses and enough material to keep Europe gabbing for years about these "wild northern barbarians." But Peter had also gained a much firmer understanding of European technology, further fueling his determination to bring it to Russia, whether Russia wanted it or not. The subsequent transformation of Russia is known as the "Petrine Revolution".

Peter first had to secure better communications with the West. At this time, Poland and Sweden effectively blocked such contact in order to keep Russia backwards and at their mercy. Peter's determination to end Russia's isolation and gain a "window to the West" as he called it, led to The Great Northern War with Sweden (1700-1721). This was a desperate life and death struggle for both Sweden in its attempt to stay a great power, and for Russia in its effort to become one. Despite the brilliance of Sweden's brilliant warrior king, Charles XII, Russia's superior resources and manpower, along with its winter, wore out the Swedes. The "Swedish meteor" which had burned so brightly in the 1600's was quickly fading away. In its place, the Russian giant started to cast its huge shadow westward and make Europe take note that a new power had arrived.

Peter's new capital and "window to the West" was St. Petersburg. Its location was less than ideal, being on marshy land, twenty-five miles from the sea up the Neva River, and in a high northerly latitude that gave up to nineteen hours of sunlight a day in the summer and as little as five hours a day in the winter. Stone for the city had to be brought in on the backs of laborers, since there were no wheelbarrows. As a result, thousands of laborers died while building this new capital, which legend said was built on the bones of the Russian people.

Meanwhile, Peter's other reforms left hardly anything untouched. He more tightly centralized the government and built up a more modern army, navy, and merchant marine along European lines. He dealt with his main obstacle to reform, the Orthodox Church, by not electing a new patriarch when the old one died. Without effective leadership, the Church could do little to fight Peter's reforms. After twenty-one years of this, Peter appointed a council, or Holy Synod, which made the Church little more than a department of state.

Peter tried to westernize the economy by first creating mines to develop the resources needed for industry. By 1725, Russia had gone from being an iron importer to an iron exporter. He brought in western cobblers to teach Russians how to make western style shoes. Anyone refusing was threatened with life on the galleys. As a result of Peter's strict measures, Russian industries grew, and with them an "industrial serfdom" tied to their jobs in much the same way the peasants were tied to the soil. Peter also worked to build up commerce and a middle class like that he saw in Western Europe. He raised the status of merchants to encourage more men to take up trade and started an extensive canal building program that connected rivers and made water transport possible between the Baltic and Black Seas. Peter tried to westernize people's lifestyles as well. He updated the alphabet and changed the calendar to get more in line with that of the West. He established newspapers, libraries, and western style schools, imported music, theater, and art from the West, and imposed European fashions upon the Russian people. Even beards were taxed, because they were not in style in Europe.

By Peter's death, Russia's economy and culture were starting to look much more western. However, many of these reforms were superficial, touching only the nobles or a limited part of the economy. For one thing, such widespread and comprehensive reforms would naturally cause a good deal of resistance and turmoil in a society as traditional as Russia. Therefore, after Peter died, there was a serious reaction against his reforms in an effort to return to the old ways. Nevertheless, Peter, by the force of his character, had so thoroughly exposed Russia to the West that there was no turning back. From this point on, like it or not, Russia was a part of Europe.

The icon and the axe

The icon and the axe have been two of the most prominent symbols of Russian culture through the centuries. The axe was used for everything from felling trees to carving spoons. It was an instrument of execution, a court weapon, and was carried by Russian musketeers, the Streltsy, to stabilize their muskets for firing. Even in modern times after its use was largely abandoned, it remained a symbol of revolution,

much as the forest, which the axe could destroy, was the symbol of traditional Russian culture.

The icon, such as the one of the archangel Gabriel (above) was adapted from the Byzantines and translated Orthodox Christian theology from words to images painted on wood that the people could understand and relate to. Icons gave divine sanction to human authority, but also humanized God, especially through the Virgin Mary.

The third part of the Trinity, the Holy Spirit, was represented in Western Europe by the dove and in Russia by the pigeon, (although the two birds are nearly identical and often referred to by either name interchangeably). This symbolism made the pigeon an object of reverence in Russia and it was forbidden as food.

The cannon and bell were corresponding symbols used in Russian towns. The bell, like the icon, was adapted from the Byzantines, but was used with much greater intensity. Since it was seen as the only proper way to praise God, all other instruments were abolished until the 1600s. There were no fewer than 5000 bells in Moscow's 400 churches. On festival days, their constant ringing drove foreign visitors crazy.

Both the largest cannon and bell ever cast were made in Russia. Both also turned out too big to use. The Tsar Cannon was cast in 1586, being over 5 meters long, weighing 40 tons, and having a caliber of 890mm. It was designed to fire only grapeshot, not the giant decorative cannonballs sitting next to it.

The Tsar Bell is 6.14 meters high, 6.6 meters in diameter, and weighed (when it was cast) 200 tons, making it the largest bell in the world and taking nearly 200 craftsmen to make it. Unfortunately, just as it was being cast in 1737, a fire broke out. The resulting uneven cooling from trying to extinguish the fire caused an 11.5-ton chunk of the bell to break off. It wasn't dug out of the ashes and finally put on a pedestal until 1836. It sounds awful.

Kizhi. While originally adapted from the Byzantines, Russia's distinctive onion domes were likely developed to shed snow.

Christianity Comes to Russia

One of the Rus' earliest encounters with Christianity was a raid on Constantinople in 907 that caught the Byzantines completely by surprise. When confronted by the chain blocking the harbor, the Rus dragged their ships overland around the chain and successfully extorted a huge bribe to go away. Encouraged by their success, they returned in 941, only this time to be met by the dreaded Greek fire, which torched half their fleet and sent the rest of the Rus scurrying back north. Hot on their heels were Byzantine missionaries who finally convinced the Grand Prince of Kiev, Vladimir, to convert.

After exploring various religions, including Judaism, which was the state religion of the Khazars, Vladimir, settled on Christianity in 987, probably because, unlike Islam, it allowed consumption of alcohol and pork. Possibly also influencing his decision was the story that his men saw choirboys suspended from the roof of the Hagia Sophia and thought they were angels. Maybe there was something in the communion wine.

Since baptismal fonts only allowed 3 people to be baptized at a time, Vladimir sped up the process by driving his people en masse into the Volga River at sword-point. Despite this somewhat superficial nature of their initial conversion, the Russian people have clung tenaciously to the Orthodox faith through the most turbulent and trying times. Given how difficult Russian history has been through the centuries, their faith has often been all they have had to sustain them.

Iconostasis

Russian Orthodoxy was heavily influenced by strict conformity to ritual and tradition. A major part of this tradition was Iconostasis, the hierarchical arrangement of icons in the Church. It was originally a low fence meant to symbolically separate heaven & the divine (the sanctuary) from earth and the human world (the nave). It would display icons of the saints' days, which were rotated with the calendar of saints' days. Since constantly changing the icons was somewhat tedious, the icons were permanently installed on the fence and rows were added on top. Thus a custom originally designed to make saints' icons and the service more accessible to the laity evolved into a wall that separated them from much of the service.

Kievan Society and the Rota System

Kievan society and state were much looser and freer than has been typical of Russia throughout most of his history. In contrast to the enserfed peasants in medieval Europe at the time, Russian peasants were free. Slavic peasants also exercised an interesting form of democracy that demanded unanimous consent on important issues. However, unanimity was often obtained by the largest group carrying clubs.

Although some ceremonial influences of Byzantine absolutism were kept, Kievan government was loosely structured. Key to this was the Rota system of succession in which, whenever the prince of one state died, all the princes below him moved to next higher state. The order of succession was as follows:

1. Oldest brother
2. Next oldest brother
3. Youngest brother
4. Oldest brother's oldest son
5. Oldest brother's next oldest son
6. Oldest brother's youngest son
7. Second oldest brother's oldest son
8. Second oldest brother's next oldest son
9. Second oldest brother's youngest son
10. Youngest brother's oldest son
11. Youngest brother's next oldest son
12. Youngest brother's youngest son
13. Oldest brother's oldest son's oldest son
14. Oldest brother's oldest son's next oldest son
15. Oldest brother's oldest son's youngest son
16. Oldest brother's next oldest son's oldest son
17. Oldest brother's next oldest son's next oldest son
18. Oldest brother's next oldest son's youngest son
19. Oldest brother's youngest son's oldest son
20. Oldest brother's youngest son's next oldest son
21. Oldest brother's youngest son's youngest son
22. Next oldest brother's oldest son's oldest son
23. Next oldest brother's oldest son's next oldest son
24. Next oldest brother's oldest son's youngest son
25. Next oldest brother's next oldest son's oldest son
26. Next oldest brother's next oldest son's next oldest son

27. Next oldest brother's next oldest son's youngest son
28. Next oldest brother's youngest son's oldest son
29. Next oldest brother's youngest son's next oldest son
30. Next oldest brother's youngest son's youngest son
31. Youngest brother's oldest son's oldest son
32. Youngest brother's oldest son's next oldest son
33. Youngest brother's oldest son's youngest son
34. Youngest brother's next oldest son's oldest son
35. Youngest brother's next oldest son's next oldest son
36. Youngest brother's next oldest son's youngest son
37. Youngest brother's youngest son's oldest son
38. Youngest brother's youngest son's next oldest son
39. Youngest brother's youngest son's youngest son

With the large number of states involved, princes were constantly moving up in status, but providing little stability on the local level. Since Russia until then was relatively isolated from invasion, this didn't matter so much.

All that changed when the Mongols came to town.

The Mongols

The Mongol invasion of Russia started as a mere scouting mission of some 10,000 Mongols in pursuit of the defeated Khwarazmian ruler Shah Muhammad and exploring the area of the Caspian Sea. At the battle of the Kalka River (1223), this Mongol "scouting party" tore apart an army of Russians after their allies, the Polovtsy, fled, leaving them to bear the full brunt of the Mongol onslaught. After the battle, the Mongols built a platform on top of their Russian

captives on which they had a huge feast, crushing their prisoners to death in the process. Those Mongols were heavy eaters.

Luckily for the Russians, before the Mongols could exploit their victory, word came that Genghis Khan had died and they had to return to Mongolia to elect a new khan, a classic example of how cultures fail to change or adapt older customs to match new circumstances.

The return of the Mongols in 1237 involved a more systematic conquest, and devastation of Russia. Over the next three years they destroyed all of the major cities of Ukraine and Russia with the exceptions of Novgorod and Pskov. Kiev was totally destroyed in 1240. Even winter didn't stop them, as they could easily cross frozen rivers and even use them as highways to track Russians into the forests in the north.

Five years after the fall of Kiev, Papal envoy Giovanni di Plano Carpini wrote:

"They destroyed cities and castles and killed men and Kiev, which is the greatest Russian city they besieged; and when they had besieged it a long while they took it and killed the people of the city. So when we went through that country we found countless human skulls and bones from the dead scattered over the field. Indeed it had been a very great and populous city and now is reduced almost to nothing. In fact there are hardly two hundred houses there now and the people are held in the strictest servitude."

The Mongols also made several attacks deep into Europe, tearing up several armies in Hungary and Poland, their most notable victory taking place at Liegnitz in 1241. The only thing to save Europe from the Mongol onslaught was the death of the Khan, which caused the Mongols to return to central Asia to elect a new leader in 1242.

The Mongols' style of warfare may have kept them from maintaining more than a temporary presence in the more heavily forested areas of Europe and Northern Russia. A Mongolian army of 20,000 men required 50-80,000 horses, which the sparse pasturage of forests could not long support. Therefore, like locusts, such a flock would have to be continuously on the move towards fresh greenery and haystacks. This problem was less acute on the grassy steppes of Central Asia, including Ukraine where they maintained a presence for 200 years.

The most successful of the Russian vassals to adapt Mongol ruling methods were the princes of Muscovy (Moscow) who earned the sole right to collect taxes and dispense justice for the Mongols, while increasingly resembling their Mongol masters in their ruling and military techniques. Eventually, the Muscovite princes turned against their Mongol masters and ended their rule in 1390. It was around Moscow that the modern state of Russia would form.

Ironically, it was another nomadic conqueror, Timur the Lame, whose defeat of the Mongols allowed Ivan III ("The Great") to win Muscovy's independence in 1390. To add irony to irony, five years later, Muscovy's indirect benefactor, Timur, sacked Moscow.

A Continuing Scourge

Mongol rule was gone, but the Mongol terror was not. Nearly every year, the horsemen of various neighboring khanates, known collectively as Tartars (or Tatars) would ride in to spread a wide swathe of death and destruction, taking thousands of Russian prisoners to the slave markets back home. These raids would depopulate whole regions of Russia. Even Moscow was sacked by the Mongols five times between 1390 and 1571. While destabilizing Russian society, these raids also forced Muscovy's princes to tighten their grip on society to provide better defense.

An English traveler passing through an area of Russia noted its prosperity. Several years later, another English traveler noted it was empty

because of Tartar raids. Life on this dangerous frontier was so unstable that the average peasant house was only built to last only about five years.

A Crimean moneychanger watching that year's crop of new Russian captives being brought in asked one of them if there were any people left in his homeland.

Ukraine comes from the word meaning "frontier". During this period, even living in Siberian towns was considered more appealing than living in Ukraine.

The word *slave* comes from the large number of Slavic prisoners enslaved in these raids.

Combating the Tartars was a major task that required total unremitting and ruthless concentration of Russia's human resources. Each spring saw the mustering of 65,000 troops, armed much like their Tartar opponents, for annual wars that gradually pushed Muscovy's line of fortresses southward.

The Tartar menace would last until 1700, during which time preoccupation with the hordes from the East left Russia more isolated than ever from European affairs.

The Third Rome, the Vegetable Lamb, and the West

The double-headed eagle was originally an East Roman (Byzantine) symbol, the two heads representing the eastern (Asian) and western (European) halves of the empire. When Muscovy's Russian rulers claimed the title of Caesar (tsar) they also coopted the double-headed eagle. Meanwhile, so had the Hapsburg rulers of the Holy Roman Empire in Germany. Later the Hohenzollern rulers

of Germany's Second Reich would do the same.

Two events in the mid 1400s combined to inspire Moscow's claim as being the Third Rome. One was the union and subjection of the Greek Orthodox Church to the Catholic Church in 1439, a desperate (and unsuccessful) move by the Byzantines to enlist Western help against the mounting Ottoman threat to Constantinople. As a result, the Russian patriarch, who now resided in Moscow, claimed he was now the supreme leader of the true Orthodox faith.

The other event came in 1453 with the fall of Constantinople to the Turks. Since the ruler of Muscovy was married to the daughter of the last Roman (i.e., Byzantine) emperor, Constantine XI, he claimed to be the successor to Roman power.

Typical of European ignorance of Russia was its "discovery" by Richard Chancellor in the 1550s. During this trip he supposedly also discovered the "vegetable lamb" which apparently sprouted living lambs like flowers that could spin on the stem like an axle and eat anything within reach. Once all the surrounding food was gone, the lamb would shrivel up and die. The plant that inspired this legend is an actual fern known as *Cibotium barometz*. A specimen of its root was preserved under glass in the 1800s (above).

Not that the West had been totally unaware of Russia. For centuries, Western powers such as Poland, Sweden, and the crusading order, the Teutonic Knights had been expanding eastward at the expense of the Russians. In 1240 Alexander Nevski, the legendary Prince of Novgorod and later Grand Prince of Vladimir, defeated Swedes on the Neva River and then the Teutonic Knights at Lake Chud in 1242. Despite these victories, Russia's troubles with the West were far from over.

One of Russia's main points of contact with the West, the city of Novgorod in the North, was viewed by rulers and the Church in Moscow with suspicion as potentially betraying Russia culturally and politically. Ivan IV (AKA the Terrible) would especially punish Novgorod for this reason, however well founded it may have been in reality.

The Livonian War (1558–1583) was largely inspired by the role of Western artillery in conquering Kazan, which led to Ivan IV wanting a better year-round port giving him access to trade with the West. This led to a 25-year long war with Poland and Sweden who wanted to block Russian access to Western military technology. Although the Livonian War ended in defeat for Ivan, it marked the beginning of Russia's long drive to become a Western power.

Russian tradition and xenophobia. The Livonian War also brought to the fore Russia's long love-hate relationship with the West. One factor contributing to this was Russia's isolation and lack of money, resulting in lower rates of literacy, including among its clergy. Thus, every word and movement of the scripture and mass assumed mystical significance in its own right and had to be done exactly as tradition dictated or it was considered invalid.

Compounding this feeling was the Orthodox Church's growing fear of the Roman Catholic Church caused by Jesuit missionary activity in the Ukraine and eastern Baltic. Using Western scholarship in debates with the less educated Orthodox clergy, they were able to convert growing numbers of people in these regions. Naturally, the Orthodox clergy saw this as an especially serious threat to their religion and became the most ardent opponents of contact with the West.

As a result, Russia had a strong anti-intellectual tradition, since that often challenged traditional practices. By the same token, Russian culture often glorified mystics and even fools as being unpolluted by dangerous intellectual ideas. In Russian there was even a saying: "He's gone to books", meaning someone had gone insane.

Admittedly, there were a number of unhealthy things imported from the West, such as syphilis in the late 1400s and vodka around 1650.

Russia and Jewish culture. Traditional Russian culture and religion was more heavily influenced by Old Testament Jewish practices than were other branches of Christianity. One of early Russia's neighbors, the Khazars, had even converted to Judaism, which may have had some influence on Russian practices, including strict rules concerning beards and food preparation.

Until Peter the Great's reforms, Russians even used the Jewish calendar, which started in 5008 B.C.E. The common belief was that the Apocalypse would occur in the year 7000 (i.e., 1492). Adding to the apocalyptic expectations in the late 1400s was the rapid expansion of the Ottoman Turks at the expense of Christianity.

Ironically, Russian culture, which was heavily influenced by Old Testament Jewish practices, developed a strong anti-Semitic strain, largely because new ideas coming from the West were associated with Jewish intellectuals. Therefore, Westernizers in Russia were called Judaizers.

There were numerous instances of popular violence against Jews and Westernizing influences. For example, Ivan introduced the first printing press into Russia, but then let a mob burn it and drive out the printers.

Ivan IV: Terrible or Awesome?

Actually, Ivan's title was Grozny, which in Russian can mean awesome or terrible. In fact, both meanings applied to Ivan at various times. On the awesome side, he did free the Russian people from centuries of slave raids emanating from the Khanates of Kazan (1552) and Astrakhan (1556), although raids did continue from the Khanate of the Crimea in the South.

However, Ivan did have a mean streak, coming mainly from a rough childhood. His father died when Ivan was only three years old, making him tsar. Apparently the boyars (Russian nobles) mistreated him privately, which warped his character somewhat.

Some of Ivan's other atrocities supposedly included:

- Dropping puppies from a tower
- Killing an elephant that failed to kneel before him
- Riding through the streets of Moscow and whipping people in the face, or beheading them if he didn't like their looks
- Skewering people with a pointed stick
- Searing victims' flesh with red-hot pans heated on a stove
- Stripping peasant women naked and using them for target practice
- Drowning hundreds of beggars in a lake
- Detonating a barrel of gunpowder (with one of his boyars on it)
- Boiling a cauldron of water (with his treasurer Nikita Funikov, in it)
- Sewing a bearskin on Novgorod's archbishop & turning the hounds loose to hunt him to death
- Tying Novgorod's women & children to sleighs, driving them into the freezing Volkhov River

Once, when displeased with a delegation's petition, he poured boiling wine on their heads, burned off beards, and had them laid out naked for further fun. Just then, a church bell fell from a tower, causing everyone to run out to see what the commotion was about. The petitioners took the opportunity to run home. Apparently, their petition was not granted.

To commemorate the conquest of Kazan, Ivan had Russia's most famous cathedral, St Basil's, built in Moscow. After its completion, he supposedly blinded the architect so he couldn't design another cathedral to rival this one.

Ivan's early reign was actually quite good. He kept human advisors and listened to grievances of his subjects without torturing them. He reformed provincial government, giving the provinces more self-rule. Most notably, he destroyed the Khanates of Kazan and Astrakhan. To do this, he used scores of artillery and engineers recruited from the Danes.

Cossacks battle Siberians during Russia's rapid expansion to the Pacific in the 1600s.

Russia's rapid expansion to the Pacific in the 1600s was much like American expansion westward to the Pacific in the 1800s, since both peoples settled vast continental interiors inhabited by relatively small populations of native peoples.

Ivan's Reign of Terror: The Oprichnina (1564-72).

While the first part of Ivan's reign can be seen as at least partly good, it fell apart in 1560, when his wife, whom he dearly loved, died. Strongly suspecting the boyars (nobles) had poisoned her, he had two of them executed without trials.

Then, four years later, Ivan loaded up his treasures on a great train of sledges and, with his few remaining trusted aides, went to the small town of Alexandrov sixty miles northeast of Moscow. A month later, two letters arrived in Moscow from Ivan, denouncing the Church and nobles, and saying he had withdrawn from the government, although he still loved the people. The Russians begged him to come back, which he agreed to do under certain conditions.

He set up the *Oprichnina* (literally a state within a state). This included half of Russia, but scattered in different pieces. Some pieces had boyars' estates, but not others. Some, but not all, blocks of Moscow were included. He even set up a puppet tsar, a recently converted Tartar, and paid homage to him.

Ivan's main purpose in this was to crush the boyars in an eight-year reign of terror. To accomplish this, he had thousands of secret police, known as Oprichniks, riding through the country dressed in black and with two objects of terror hanging from their saddles: dogs' heads (to worry Ivan's enemies) and brooms (to sweep Russia clean of his enemies).

Not just individual boyars, but whole cities were terrorized. Novgorod, suspected of treason, underwent a 6-week slaughter in which 1000's were mutilated, roasted in the public square, or thrown into the river where Oprichniks waited in boats to shove their heads under the ice.

At Aleksandrov where Ivan presided over weird parody of a monastery, lecturing to his drunken "monks" or Oprichniks. Even the pious Ivan, who customarily sent names of his victims to monasteries so monks could pray for them, lost count and rationalized "God knows their names". In the midst of this chaos, the Tartars sacked Moscow (1571).

In 1572, Ivan finally put an end to this madness. It's impossible to estimate how much damage the Oprichnina did to Russia.

Ivan's death. Ivan accidentally killed his most capable son and likely heir in an argument over his whipping his pregnant daughter-in-law for the way she dressed. Ivan's eldest son had already died when a careless nursemaid dropped him into a freezing river. Below: Ilya Repin's painting of Ivan IV's grief after accidentally killing his son

In later life, Ivan was addicted to swallowing mercury, probably contributing to his pre-existing mental instability and such behavior as reportedly wandering through the palace howling like a wolf. Ivan died in 1584 while

playing chess. But Russia's troubles were far from over.

Cossacks

The Cossacks were a mix of Tatars, runaway Russian and Polish Peasants, and anyone else who wanted to join them, including some Germans. There were different Cossack hordes stretching from Poland and Ukraine eastward across Siberia. The features common to these various groups were their fiercely independent nature and Orthodox Christian (usually Old Believers) faith.

Russian Cossacks were loyal to the Tsar, but quick to rebel if they thought his rule was tyrannical. They were also ardent Old Believers who resisted Patriarch Nikon's religious reforms in the 1600s. They were especially renowned as horsemen, being perfectly adapted to the open and mobile warfare of the Steppes. The Tsars used them as their main defensive and offensive forces against the Tatars and Turks. Likewise, Poland used them to defend against Turkish and Tartar attacks.

Cossacks also raided Turkish and Tatar shipping on the Black Sea, swarming aboard enemy ships from long boats carrying some 70 Cossacks each. Such raids would typically be launched just before dawn to gain the element of surprise. Below: Zaporozhye Cossacks writing an insolent reply to the Turkish sultan in a painting by Surikov.

The Time of Troubles (1598-1613)

Ivan's reforms and purges made his reign a turbulent and costly one. Also, Ivan's accidental slaying of his most able son in a fit of passion left the throne to the feeble-minded Feodor, who liked to spend most of his time praying and ringing church bells. The reins of government thus fell to the boyar, Boris Gudonov, who succeeded Feodor as tsar in 1598. At this point, everything in Russia seemed to go wrong at once. The Boyars resisted his attempts to increase royal power. The Orthodox Church thwarted Boris' early attempts to bring Western European knowledge and culture to Russia

An unlucky reign. Among Boris Godunov's more unpopular and/or unsuccessful policies were:

- Giving Important offices to foreigners
- Encouraging economic ties with the West
- Encouraging Russian men to shave their beards
- Proposing the marriage of a Danish prince, a Lutheran "heretic", to his daughter, luckily the prince died
- Trying to destroy the boyars who had escaped Ivan's Oprichnina, but some like the Romanovs, escaped
- Trying to set up a university in Moscow, but the Church stopped it as foreign contamination. Therefore, he tried sending 30 Russians to study abroad, but 28 of them defected.

Worst of all, a horrible drought and famine in 1601 killed millions of peasants who revolted out of desperation and the belief that the famine was the tsar's fault. The rebels got help from the Poles, who supported a supposed son of Ivan IV as tsar. Boris successfully defended his realm until, right on the verge of victory, he suddenly died, capping off a remarkably unlucky reign.

After killing Godunov's son, Fyodor II, the Poles installed False Dimitry I. However their arrogant behavior led to False Dimitry I being overthrown and his remains being shot back to Poland from a cannon.

The boyars gave the crown to Prince Vasily Shuysky, a leader of the revolt against Dmitry, with the understanding that he would respect the special rights and privileges of the boyars. While the new tsar had the support of most boyars and of the northern merchants, he could not end the disorders in the south or fighting on Russian territory in the North between Poland and Sweden.

In 1608 a number of boyars, led by the Romanovs, supported a second False Dmitry, who rode a wave of discontent and brigandage from the Cossack south into the center of Muscovy. A kind of shadow government was formed in the village of Tushino, 9 miles (14 kilometers) west of Moscow, in which the boyars and bureaucrats of the Romanov circle took leading posts. It managed to gain Cossack support & manipulate Dmitry's pretensions while negotiating with the Polish king Sigismund III on terms by which his son Wladyslaw IV might become tsar.

Shuysky, in desperation, turned to Sweden for aid, promising territorial concessions along the Swedish-Muscovite border. At this the Polish king invaded Muscovy and besieged Smolensk (September 1609). The Tushino coalition dissolved, and Dmitry withdrew to the south. The position of the Shuysky government deteriorated, and in 1610 the tsar was deserted by his army and his allies.

One of the most famous incidents in the Time of Troubles was the Defense of the Troitse-Sergiyeva Lavra against the Poles in 1610. This monastery guarded the northern approaches to Moscow and was defended by a mix of some 2,200 Russian nobles, peasants, monks, and streltsy (Russian musketeers) against a Polish-Lithuanian army of 15,000. The siege lasted from September 23, 1610 to January 12, 1611. Both sides suffered heavily in this siege, the

Russians mainly from scurvy, until the Poles retreated upon the approach of a Russian relief force.

The boyars formed a 7-man provisional government for installing a Polish tsar, but it couldn't settle its affairs & restore order to the country. A new insurgent army, financed by northern merchants and staffed with Swedish troops, marched on Moscow with the intention of ousting the Polish garrison and of bringing the various Cossack bands under control. It nearly gained Moscow but fell apart because its leadership could make no arrangement with the Cossack leaders.

A year later, a second force, raised in the same northern cities and supported by Cossacks who had been part of the Tushino camp, was able to take possession of the Kremlin. A call was issued for the election of a new tsar.

By this time, the anarchy had gotten so bad, even by Russian standards, that resistance to the foreign invaders coalesced around the Church. By 1613, the foreigners had been ousted and order restored. The popular assembly, known as the Zemsky Sobor, chose Michael Romanov as the new Tsar. His dynasty, the last in Russia history, would rule Russia until its overthrow by the Russian Revolution in 1917.

Russia's Great Schism

As mentioned earlier, the Russians were very strict and conservative in their religious obligations. This was especially true of those known as the Old Believers. Among their customs was to remove the crucifix from one's wife and cover any icons before sex. They also believed they couldn't go to church without first bathing, even in winter. Keep in mind they air-dried themselves outside. Also, the church service had no chairs, so worshippers would stand for hours at a time. Believing God only meant human voices to make music, they rioted and destroyed six carriages of European instruments entering Moscow in 1649.

In 1651, Tsar Alexis I, a very pious tsar, elevated an ardent reformer, Nikon, as Patriarch of the

Russian Orthodox Church. The next year, Nikon introduced a number of reforms that were designed to get the Russian Church back in line with Greek Orthodox practice. The full list of these reforms occupied 400 pages of text, but some of the more controversial ones were:

- Changing “And in the Holy Spirit, the *True* Lord and Giver of Life” to “And in the Holy Spirit, the Lord, the Giver of Life”
- Changing how the number of fingers used in making the sign of the cross from two (symbolizing Christ’s dual divine and human nature) to three (symbolizing the Trinity) and how the fingers are held
- Changing the number of times one genuflects (kneels) at one point in the service from twelve (the number of apostles) to four (the number of gospels)
- Changing the direction of the Church procession from turning clockwise to counter-clockwise.
- Changing the number of Prosphera (loaves of bread used in the liturgy) from seven to five
- Changing the number of times the *Alleluia* is said from two to three
- Changing the Easter procession from turning clockwise to counter-clockwise.

Boyaryn Morozova being taken to prison for her opposition in 1671 to Nikon’s reforms. Old Believers show her support by making the cross with two fingers, instead of the newly mandated three fingers.

Nikon also tried to make the faithful spend 4 hours a day in church and ban drinking. Eventually he even challenged the tsar’s power and was finally exiled. But the damage was done as the conservative Old Believers continued to protest. Many of them fled to the frontiers to establish new communities. In some extreme situations, whole congregations burned themselves (women and children too) in their

churches. Between 1684 and 1690 an estimated 20,000 Old Believers died this way. The most radical Old Believer, Avvakum, claimed a vision where Christ revealed Fedor’s father, Alexis was in hell for supporting reforms. This split in the Russian Church, know as the Great Schism, would last all the way to the Russian Revolution in 1917.

Moscow in the 1600s

Moscow in the 1600s was a city of wooden houses, many of them pre-fabricated, customers just specifying to suppliers the number and sizes of rooms they wanted. When it rained, Moscow was also a city of mud where people could sink up to their heads in the middle of the street, and many just stayed home. One might see drunks lying naked in the streets, having sold their clothes for one last drink. The poorhouse also doubled as a morgue, where unclaimed bodies lay in coffins made from hollowed out logs, waiting for someone to claim them. Heavy rains and the spring thaw could be dangerous times for Muscovites, since one could not get supplies into the city.

Dominating the city was the Kremlin (Russian for “fortress”). Its triangular wall was sixty-five feet high, twelve to sixteen feet thick, and 1.5 miles long, containing an area of 69 acres. It was also ringed by two rivers, a moat, and 29 massive towers, each a self-contained fortress. False Dimitry held out here for two years during the Time of Troubles before he surrendered and his ashes were fired back to Poland.

Within the Kremlin were three cathedrals, two of them designed by Italian architects. The largest, Assumption Cathedral (Uspensky Sobor) had a huge dome supported by four massive columns. The Cathedral of the Archangel Michael was the Tsars’ burial place until Peter I.

Bells were especially popular with the Russians. The triple consolidated bell tower of Ivan the Great, the Bono Tower, and the tower of Patriarch Philaret had a cupola 270 feet high with rows of bells of copper, silver, bronze, and iron, one weighing 31 tons. Answering the Kremlin bells would be the bells from Moscow’s

other 400 churches so that "the earth shook w/these vibrations like thunder". Moscow's bells would sometimes ring all night, driving foreigners to distraction.

The Tsar

The tsar lived a life surrounded by ritual, especially of a religious nature. Much like the Byzantine emperors on which so much of Russian culture was modeled, the life of the tsar was seen as a stylized reflection of Christ in Heaven. Alexis I, Peter the Great's father, was especially religious, rising at 4AM when he would pray for 20 minutes, kiss the icons and be sprinkled with holy water. He would then get the Tsarina (empress) and go to mass.

"If he be well, he goes to it {every religious rite}. If sick, it comes to him in his chamber. On fast days he frequents midnight prayers, standing four, five, or six hours together, prostrating himself on the ground, sometimes 1000 times, and on great festivals, 1500."-- Dr. Collins, who estimated Alexis fasted eight of twelve months, taking only three full meals a week.

After hearing petitions from boyars, some of whom would bow thirty times before addressing him, he would go to another mass for two hours, during which he would also carry on business. After that came administrative work until the midday meal, most of which he gave to boyars, followed by a three-hour nap and then Vespers mass, where he conducted more business. Then came an evening meal, after which he relaxed by playing chess or backgammon or listening to stories. The tsar also liked to hunt, having 200 falconers to care for his 3,000 falcons and 100,000 pigeons.

When addressing the Czar, one must use his full title. Accidentally omitting just one word was seen as treason. Although a number of these were added after 1700, the tsar's full title according to the constitution of 1906 gives some idea of what addressing him properly would involve:

Emperor and Autocrat of all the Russias, Tsar of Moscow, Kiev, Vladimir, Novgorod, Kazan, Astrakhan, of Poland, Siberia, of Touric

Chersonese, of Georgia, Lord of Pskov, Grand Duke of Smolensk, of Lithuania, Volhynia, Podolia and Finland, Prince of Estonia, Livonia, Courland and Semigalia, Somogotia, Bialstock, Karelia, Tver, Yougouria, Perm, Viatka, Bulgaria, and other countries; Lord and Grand Duke of Lower Novgorod, of Chernigov, Riazan, Polotsk, Rostov, Yaroslav, Belozero, Oudoria, Obduria, Condia, Vitebsk, Mstislav and all the region of the North, Lord and Sovereign of the countries of Iveria, Cartalinia, Kabardinia, and the provinces of Armenia, Sovereign of the Circassian Princes and the Mountain Princes, Lord of Turkestan, Heir of Norway, Duke of Schleswig Holstein, of Storman, of the Ditmars, and of Oldenbourg, etc

Proverbs about the Czar showed the near godlike status he held in Russian society:

"Only God and the Czar know."

"It is very high up to God; it is a long way to the Czar."

"The sovereign is the father; the earth [is] the mother."

Granovitaya Palace in the Kremlin had a massive throne and reception room 70 feet by 77 feet. Very little light in the palace so that candles had to be used even on summer days. Modeled after the Byzantines, it had two bronze lions that rolled their eyes and roared. There was a curtained window toward the ceiling of the throne room so the cloistered women of the palace could watch the proceedings without being seen. The tsar's study had a box he could lower to ground level for petitions.

The Tsar's bedchamber. The fancy white structure to the right is a traditional Russian stove for heating the room. On cold winter nights, peasants would sleep on top of such stoves to keep warm.

Women in Tsarist Russia

Russian women, following the Byzantine model, were treated like helpless children. In good upper class families, boys and girls didn't even play together. Lower class women were more essential to their husbands' economic welfare and typically had more freedom to socialize, etc. To that effect, peasant women preferred working with a distaff, to a spinning wheel since it was portable and could be taken to friends' houses where the women could socialize while working.

Marriages were arranged by the groom and two fathers to negotiate a dowry and determine proof of the bride's virginity. When the girl, wearing a veil, was introduced to her future husband, her father lightly whipped her on her back and handed the whip to her fiancé, who would say he wouldn't need it but hung it on his belt just the same. At the wedding, the girl fell at the groom's feet and touched her forehead to his foot, upon which he benevolently covered her with the hem of his coat as sign of his responsibility to protect her. Right after the ceremony, the happy couple went to bed for two hours, after which everyone crowded in to confirm she was a virgin. Below: a boyar (noble) wedding. Note the submissive demeanor of the bride.

The wife's duty was to tend house, see to her husband's comfort, and bear his children. Displeased husbands typically beat their wives and were encouraged to do so. Divorce involved putting the wife in a convent where she was considered "dead", which allowed the man to remarry. However, the Orthodox Church only allowed a man three wives, so he tended to treat the third one more carefully.

Daughters and sisters of the tsar were especially secluded in the women's quarters known as the Terem. Since they were not allowed to marry

foreigners (who were heretics, except for the Byzantines who were gone) or those below them in social status, there was no one they could marry. Thus they were virtually condemned from birth to a life of seclusion in the Terem. When they were sick, they were even examined through gauze so male hands couldn't touch them. Much of that was about to change with Natalya Naryshkina, Peter the Great's mother.

Peter the Great's Mother

Peter the Great's mother, Natalya Naryshkina, along with Peter's half-sister, Sophie, would lay the foundations for changes in the status at least of upper class women in Tsarist Russia. After them, four women would rule Russia in their own rights as tsarinas.

Natalya's husband and Peter's father, Tsar Alexei Mikhailovich (1645-76), was highly educated, passing a new law code on his own authority in 1649. In foreign policy, he unified Russia and Ukraine and prevented an incursion by the Crimean Tartars. His most controversial act was support of the patriarch Nikon's reforms, which sparked the Great Schism in the Russian Orthodox Church. He had 21 children from his two marriages, although only three of his sons survived him, and only one of those for more than a few years and in good health. That son was Peter.

In 1669, Alexei's first wife, Maria Miloslavskaya, died in childbirth. Although four of her five sons survived her, 2 died only six months later and the other two were feeble. Therefore, Alexis began to look for a new Tsarina to ensure the succession. One of his friends, Artemon Matveev, was fascinated with Western culture and even had a Western wife who shocked Russians by dining with the guests and joining in the table conversation. Matveev also had a young 19-year old ward, Natalaya Naryshkina, who charmed the 40-year old Czar. Although

pleased that Alexis wanted to marry her, Matveev was also afraid of the jealousy from the Miloslavskys (the previous tsarina's family) and other powerful Boyars, since a tsarina's family typically had great power and influence.

Therefore, he insisted the tsar go through the traditional beauty pageant process, another custom going back to the Byzantines where noble families would put their young unmarried women up for the emperor to choose the most desirable (and eligible) woman as empress. Not surprisingly, competition was incredibly fierce. In 1616, one family drugged a rival girl, had her declared ineligible, and her family exiled to Siberia for presenting such a girl to the tsar. Alexis' first choice in the pageant of 1647 had her hair twisted so tightly by rivals that she fainted, so she was declared unhealthy, and her family was exiled to Siberia. Natalya won, even after going through all the traditional motions, but Matveev was still charged with using magic herbs to influence tsar's choice. This delayed the marriage nine months, but didn't stop it.

Natalya, like her step-mother, had a semi-Western education and started making radical changes at court, getting the tsar to revoke his old decrees against dancing, playing or watching games, and singing and playing musical instruments at weddings. Not that this always worked. Her initial attempt to blend a Russian choir with Western style polyphonic instruments was a disastrous cacophony described as sounding like a "*flight of screech owls, a nest of jackdaws, a pack hungry wolves, and seven hogs on a windy day*" (Dr. Collins). The tsar even patronized the theater to please his bride, attending a 10-hour Biblical play.

Natalya preferred the less formal and stuffy atmosphere of the suburban palace, Kolomenskoe, where she could more easily watch embassies and other court functions. Even more shocking was her habit of traveling with her carriage curtains open so she could see outside, but also allowing common people to see her, something forbidden in Russian society.

This was the woman who would give birth to Russia's most famous tsar.

The Young Tsar's Childhood

Peter I was born May 30, 1672. Thanks to the custom of making an image of the patron saint the same size as the tsarevitch (crown prince) at birth, we know that he was 19.25" long and 5.25" wide at birth—a big baby who would grow to a huge size as an adult.

The celebration of Peter's birth included a sugar model of Kremlin. He was tended by a governess, a wet nurse, and a staff of dwarves to act as his servants and playmates. His father, mother, and Matveev lavished all sorts of gifts on him, such as music boxes from Germany and a miniature gilded carriage with dwarf ponies and four dwarf attendants. However, his favorites were military toys (drums, toy soldiers, forts, swords, pikes, arquebuses, etc.), and especially a gift from Matveev, a model ship.

The young tsars. In 1676, when Peter was not yet four years old, Alexis died. Peter's 15-year old half-brother Fedor, who had been named Alexis' successor without any expectation of him surviving his robust father, succeeded to the throne. In fact, Fedor's legs were so swollen he had to be carried to the coronation. More significantly, this brought about the return of Fedor's family, the Miloslavskys, who got Matveev exiled to the Arctic Circle after unsuccessfully trying to get Fedor to have him executed. However, Peter, as a royal prince, was sacrosanct and safe.

As tsar, Fedor did abolish the law of precedence, which automatically gave offices to higher ranked nobles, and even publicly burned the records of rank. Instead, offices were given on the basis of merit. Ironically, many nobles cursed Fedor for his progressive reform and favored the young Peter who would carry this idea much further.

At age 5 Peter started his lessons, memorizing long Biblical passages and the Russian choral litany, which he remembered all his life. Even as an adult, he would walk into a country church, join the choir, and sing loudly. He was also interested in history and battles and commissioned picture books showing cities,

battles, ships, weapons, etc. He also had a giant globe larger than a man brought from Europe.

When Fedor's wife died in childbirth, he was married to the high-spirited 14-year old goddaughter of Matveev, who was brought from exile back to court. Soon afterward, Fedor died, triggering an argument over which brother, the sick but older Ivan Miloslavsky, or the healthy but younger Peter Naryshkin, should be Czar. Since it would take weeks for the Zemsky Sobor (Russian parliament) to gather, it was decided to let "the people" decide, and the Moscow crowd chose Peter.

Revolt of the Streltsy. The Streltsy were 22 regiments of professional musketeers and pike men formed by Ivan IV to supplement his feudal cavalry and peasants. They were mostly Old Believers and very suspicious of growing foreign influences. In peacetime, most of them were stationed in Moscow as the tsar's honor guard. Having little to do, many of them became merchants, since they paid no taxes. Thus, the Streltsy were very wealthy, and Streltsy membership was highly coveted and virtually hereditary. This also made it hard to get them to fight and risk their lives in battle.

Making matters worse, colonels often stole their men's pay, which led to petitions that were usually ignored, while the petitioners were punished. When one such petitioner was about to be punished, he appealed to his fellows, causing seventeen regiments to mutiny against their officers.

When Natalya's new government allowed them to beat their officers the Streltsy had greater sense of their own importance. Then Sophia Miloslavsky, Peter's half sister, spread the rumor that the Naryshkins had poisoned Fedor and were plotting to kill the Miloslavsky's and replace traditional Russian culture with foreign ways. Thus the Streltsy revolted again and stormed into the Kremlin and palace.

Natalya showed that both Peter and Ivan Miloslavsky (Peter's other half brother) were safe and Matveev, popular with the Streltsy,

gave a speech to calm them down. However, after he left, an officer threatened to punish the Streltsy, causing the riot to erupt again. This time, it turned into a bloodbath as the Streltsy scoured the palace for three days, killing all the Naryshkins they could find (below). Sophia, with her enemies now out of the way, had her brother, the feeble Ivan, elected co-tsar along with Peter and herself chosen as regent. As a result of all this, Peter hated Moscow and the old ways in much the same way Louis XIV, who underwent a similar experience as a child, hated Paris.

Peter's games. Except for mandatory rituals as tsar alongside the sickly Ivan, Peter spent most of his time out of Sophia's way in the country at Preobrazhensky Estate. As tsar and a big rambunctious boy, there was no one who could tell him what to do, and Sophia was glad to let him waste his time in the country. Therefore he spent his time exploring and playing wargames, but receiving little formal education.

Peter's interests got him involved in a variety of crafts: type setting and book binding, lathe turning, blacksmithing, clock making, carpentry, stonemasonry, and the use of sextants. However, with no real formal education, he would be a virtually illiterate tsar, something he regretted later.

One day he found the rotting remains of a boat in a shed, which fed his growing fascination with ships and the Westerners who built them. He had the boat fixed up and would sail it around on a lake, which got his mother increasingly worried about her son. Therefore, she arranged a marriage at age 16 to a properly submissive Russian noble girl. But the marriage was a disaster, as she didn't like to sail boats or fire guns, so Peter quickly got bored of her and moved on to other hobbies, in particular, wargames.

Peter's wargames required strict discipline, marches, digging trenches, maintaining supply lines, etc. He took part as one of the men, at first as a drummer and later as a bombardier, since they got to make the most noise and have more fun than the officers. This had an important effect on Peter, fostering in him an attitude of promotion by merit. Peter even formed a regiment of 300 comrades, which in later years would become the tsar's honor guard, the Preobrazhensky Regiment.

As Peter got older, his games got more serious, including the use of live ammunition. This led to growing orders for more weapons and gunpowder, which Sophia obliged him with, probably hoping he'd end up getting killed.

Peter's games also got progressively more dangerous. In one of his elaborate fireworks displays a 5-pound rocket that failed to explode fell on a boyar's head and killed him. His wargames also became more elaborate and dangerous, using live ammunition. Peter himself was wounded, his mentor, Gordon, was shot in the thigh, and a prince was killed. After a bitterly fought 2-day game, Peter was not satisfied with the results, and had it repeated on a rainy day.

The games' growing seriousness (e.g., a complex fort which took a year to build) also led to a growing need for professional officers to run these operations. Sophia apparently felt no threat from these and even loaned officers and streltsy to Peter until her campaign against the Crimean Tatars compelled her to recall them from Peter's games. This brought Peter to the German Suburb.

Founded in 1652 after a Streltsy uprising and attacks on foreigners, the German Suburb was a settlement of about 3000 foreign (i.e., European) mercenaries just outside of Moscow. Although mercenaries from all parts of Europe lived there, it was called German since the first foreigners employed in Russia were mostly German and the Russians felt all foreigners were the same.

This community was an enclave of European civilization just outside Moscow with broad tree-lined avenues, two and three-story brick houses, well ordered gardens, reflecting pools, and fountains. It contained Catholics and Protestants living together in relative peace, their religious differences mollified by the long distance from home. Protestants could have their own churches, but Catholics had to say mass in their homes. Since they were often prohibited from leaving Russian service once they had come there, the mercenaries typically married Russian women, put down roots there, and adopted many Russian ways.

The German Suburb was an important mechanism of change for Russia, drawing more curious and progressive Russians there to learn about the West. Among its most frequent visitors was Peter, for whom this was possibly the closest thing he had to a family and school, teaching him not just about Western military technology, but also the less refined habits of soldiers such as smoking, drinking, and chasing women.

Peter made two especially influential friends there: General Patrick Gordon and Francis Lefort. Gordon (1635-99) was a Scottish Catholic and royalist who left England after the English Civil Wars. He served with the Swedes, was captured by and defected to the Poles, went back to the Swedes and back again to the Poles, all by age 25.

He was then attracted to "three years' service" in Russia, only to find out that three years meant as long as the Russians wanted him, threatening to send him to Siberia if he tried to leave. Therefore, he made a life for himself in Russia with a wife and children, who were held hostage in Russia when he went to Europe on official business. Peter became Gordon's protégé and student, learning all he could of military matters from him. When Gordon died, Peter closed the old soldier's eyes.

Francis Lefort was a Swiss Mercenary who shared Peter's taste for partying.

He was urbane, sophisticated, and had a talent for organizing parties, balls, and banquets. Although not much of a deep thinker, he symbolized much of what appealed to Peter of Western Europe. Lefort was nearly as big as Peter and was one of two people who could calm him down in his convulsions. However, even he couldn't keep up with Peter's wild energetic lifestyle and died around age forty, probably from too much partying.

Lefort also provided Peter with the wild boisterous women he preferred to the passive Russian women of the Terem, including his first mistress, a German woman, Anna Mons, whom he took around with him in public, and who could match Peter drink for drink. Therefore she was his mistress for twelve years.

Of women, Peter had plenty, but he preferred peasant stock, since they were cheaper to keep around and his tastes were less than refined anyway. His one true love and eventually his wife and empress was Catherine I, a peasant whose cheerful, understanding nature won his heart. She accompanied him on campaigns, kept her hair short, slept on the ground, and didn't flinch at sight of men being shot—all the things a man like Peter looked for in a woman.

Peter was given to violent convulsions and contortions of body and neck, possibly epilepsy or the results of venereal disease, and only Anna and Lefort could soothe these. Anna largely overcame court resentment of her origins by interceding to save many of them from Peter's wrath. Peter was careful not to show his temper in front of Anna and would even conceal severe sentences from her.

After Peter, every adult male Tsar married a foreign woman, which would have a great influence on Russia

Sophia's Regency and Downfall (1682-89)

Peter's half-sister, Sophia (above) ruled quite capably as his regent, even participating in council meetings, something virtually unheard of for Russian women. Helping Sophia was her lover and prime minister, Vasily Golitsyn, who was even more heavily westernized than Medvedev had been, probably making him all the more attractive to the progressive regent.

Sophia tried to follow a peaceful policy with Russia's neighbors, realizing that a woman trying to lead the army could be quite risky. One problem Russia had was with Poland over possession of Kiev, which Russia had taken in 1662 and promised to give back in two years. However, since Kiev was primarily Russian and Orthodox, Russia wanted to keep it, which was a sore point with Poland.

Then, in 1683, Poland's Jan Sobieski led the relief of Vienna from the Turks, starting the War of the Holy League. When the Turks beat the Poles in 1685, the Poles needed help, leading to a treaty giving Russia Kiev in return for attacking the Turks' vassals, the Azov Tatars. As a result, Russia's hitherto excellent relations with the Turks were now gone.

In 1687, upon the Boyars' insistence, Golitsyn led an expedition of 100,000 men against the Tatars. Very simply, the Tatars just burned the grasslands in the Russians' path and leaving them no forage for their horses, forcing the Russians to retreat, losing up to 45,000 men.

A second expedition started in December 1688, leading to great suffering from the cold and mud. However, advance parties of Russians had burned the grasslands, so there were new green shoots just emerging by the time the Russian army got to them. Daily raids by Tatar cavalry were driven back by artillery until the Russians

reached Tatar fortifications across the Isthmus of Perekop in Crimea. Golitsyn, unwilling to attack without siege equipment, unsuccessfully tried negotiating and then retreated.

Sophia overthrown. Peter was angry over this fiasco and especially at having to preside over a sham ceremony rewarding Golitsyn for his supposed victory. Tensions were growing between the two sides.

They exploded in 1689 when Sophia ordered a larger than normal escort of Streltsy to gather in Moscow for a pilgrimage to a local monastery where a murder had recently occurred. Concerns grew in Moscow over a repeat of the Streltsy bloodbath of several years earlier.

Then an anonymous letter came to Sophia, warning of Peter taking his play regiments to attack her and Peter's co-tsar, Ivan. As Sophia reacted by gathering more streltsy, Peter's followers hustled him from his sleep at Preobrezhenskoe to the safety of Russia's holiest (and heavily fortified) monastery, Troitsky. Peter gradually tightened noose, summoning Russian and foreign officers to abandon Sophia and come to his side, which they did since he was the tsar. Also, the streltsy and patriarch hated Sophia's westernizing policies, not realizing to what extent the young Peter would go to westernize Russia. But that was all in the future.

Bit by bit, Sophia's support eroded away until she surrendered and was exiled to a convent. Although comfortably imprisoned and not forced to become a nun, she still found these conditions intolerable compared to the unprecedented freedom (for a Russian woman) she had held. Golitsyn, who had acted in good faith and not explicitly against Peter, was exiled to the Arctic where he lived until his death in 1714 at age 71.

Sophia's government had been competent and another step in Russia's westernization, thus paving the way for Peter, whose reign seems more evolutionary than revolutionary in this light. Sophia also signified a giant step for Russian women. After her four women would

rule Russia as Tsarinas, largely, owing their positions to her. Thanks to her, there was an almost unimaginable gulf between Russian women (at least nobles) of the 1600's and 1700's.

The Character of the Tsar

Peter's official court portrait and how he preferred to look

Peter was a huge and powerful man, especially for his times, being 6'8.5" tall. With his bare hands he could supposedly bend iron nails and roll up a silver plate like a piece of paper. He also had a violent temper, and was given to pummeling even his most trusted ministers and friends with his powerful fists. Other than that, he didn't look the part of a divinely appointed ruler, adopting a sloppy lifestyle and dress because he was too preoccupied with more important matters. Although he had little formal education, he did have an intense fascination with anything mechanical, especially clocks, which he could take apart and reassemble.

He especially prided himself on his dental skills and carried around a bag of teeth he had forcibly extracted from people dumb enough to admit to a toothache. Given his size and strength, he was perfectly capable of holding someone down in a chair and extracting teeth until he found the right one. Once when his valet complained that his wife denied performing her marital duties on the pretext of a toothache, Peter summoned her and extracted a perfectly good tooth to teach her a lesson.

Peter also had a crude sense of humor. For example, he forced one aide to eat a tortoise and another to drink a flagon of vinegar. He also found it funny to force little girls to drink large amounts of brandy.

The All-joking All-drinking Synod of Fools and Jesters (AKA The Jolly Company) was a motley collection of foreigners and boyars with whom Peter partied. And, as with anything else in his life, Peter didn't party in half measures.

A typical banquet with the Jolly Company lasted from noon till dawn, though some lasted two or three days, involving gargantuan meals with intervals for smoking, bowling, archery, and target practice with their muskets. Toasts were accompanied not just by cheers and shouts, but also blasts of trumpets and salvos of artillery. Revelers would sink to the floor, pass out, wake up and start partying again, only to pass out again later on.

Peter believed hard drinking was the measure of a man and once arranged a drinking bout between his confessor and a high-ranking French prelate. After an hour, the Frenchman rolled under the table and Peter hugged his confessor for saving the honor of Russia. Peter could maintain a phenomenal pace of heavy drinking all night and then getting up at dawn to work in the shipyards or whatever he was doing that day.

Eventually Peter's parodies were organized for religious mockery, although he specifically mocked the Catholic Church to avoid offending devout Orthodox Christians. He gave his followers mock titles such as "prince-pope", cardinal, bishop, priest, and deacon (Peter's title). The group was devoted to Bacchus, with the prince-pope, Peter's old tutor, blessing drinking bouts by making the sign of the cross with two long-stemmed Dutch pipes.

Holiday rites were especially elaborate. At Christmas, Peter and up to 200 of his friends would ride around hanging out of sleighs, led by the prince-pope wearing a costume of a tin hat and clothes sewn with playing cards, while perched on a barrel in a sleigh drawn by 12 bald men. They would burst unexpectedly into the homes of nobles and merchants expecting food and drink in return for uninvited (and inappropriate) songs. At Lent, this procession of "penitents", dressed in outlandish costumes

worn inside out, rode around on donkeys and oxen or in sleighs drawn by pigs, goats, and even bears.

Peter put on an especially elaborate wedding for his favorite jester, Jacob Turgenev, Jolly Company wearing birch bark hats, straw boots, mouse skin gloves, coats covered w/squirrel tails and cats paws. The celebration, which ended with the triumphal entry into Moscow of the happy couple on a camel, was apparently so much fun that the groom died suddenly a few days later.

Ironically, Peter ran an austere, and downright cheap court, donating his own money to achieve his goals.

Peter's Early Reign Through the War of Azov (1689-97)

Peter's government after Sophia. Although Peter was now undisputed tsar, his reign, which began officially in 1682, did not start effectively at age 17 in 1689 with Sophia's fall, but in 1694 at age 22, resulting in corrupt and disinterested government for five years without Sophia's competent hand at the helm. Instead, Patriarch Joachim and the conservatives ruled, leading to tighter restrictions on foreigners, ordering expulsion of the Jesuits, reading all foreign mail, and stopping them at the border until they got permission to enter Russia. Joachim wanted to destroy the German Suburb's Protestant churches, and was only stopped by Tsar Alexis' decree protecting them.

Xenophobia reached such a peak at this time that a Moscow mob burned one foreigner alive.

When Joachim died, Peter was relieved and wanted to replace him with a more liberal patriarch. However, public pressure forced him to accept another conservative who did not speak barbarous languages, had a beard big enough for a patriarch, and whose coachmen drove his coach riding the horses, not from a seat on the coach.

Peter's war against the Turks of Azov (1695-97). Not surprisingly, Peter's active reign started

with a war, taking on the Tartars of the Crimea who were still carrying off up to 15,000 Russian slaves per year. He also was still obligated by treaty to help Poland and the Holy League against the Turks in return for keeping Kiev.

His first expedition consisted of two armies: one a traditional Russian force of 120,000 men, including a lot of peasant draftees, to divert the Turks away from their capital at Azov. The second force was made up of 30,000 men with Western officers and new guard regiments trained with modern weapons in Western tactics. Peter, as was his custom, served as a common bombardier, although everyone knew who was really in charge.

The Expedition was badly organized (not even having a fleet to blockade Azov), badly disciplined (the *streltsy* refusing to follow Western officers), and poorly supplied since Tatar cavalry raided the Russian supply wagons. There were few experienced siege engineers, so Peter sent for some from Austria.

Even worse, the Russians took a daily nap. Thus when a Dutchman, Jacob Jensen, defected to the Tartars, they attacked while the Russians were snoozing, inflicting heavy casualties. After an ill-advised assault that got 1500 men killed, the Russians embarked on a disastrous retreat without supplies. As a cover-up, Peter held a bogus triumphal parade in Moscow, although it only had one prisoner to display.

However, Peter was far from finished.

First of all, he ordered a fleet of 25 galleys and 1300 more barges built during winter! Not having a galley to serve as a model, he cut a Dutch-built galley at Archangel into parts and took the parts overland to serve as a model for the Russians to copy. They built the galleys in sections and then hauled them overland to Voronezh for assembly.

Thus in the spring of 1696, Peter had the galleys, transports and 70,000 men to sail down the Don River to renew the attack on Azov. This time,

Peter served as a ship's captain rather than bombardier, because that was more fun.

The Turks, not expecting Peter to return, had left their siege works intact so the Russians were able to move right back in and renew the siege. With the help of Austrian engineers who arrived mid-July, Azov fell after a 2-month siege. In his triumphal parade, Peter marched with the other captains, only distinguished by his huge size and a white feather in his hat.

The Azov War had taught Peter that for Russia to become a great power it had to learn as much as it could about Europe. Thus began his life's work to Westernize Russia.

The Great Embassy (1697)

The Great Embassy (1697) was a huge party of some 250 people, including Cossacks, musicians, dwarves, and nobles. Peter himself went "incognito" as a gunnery officer and shipwright, although it was the worst kept secret in Europe since he was 6'8.5" tall and had a distinctive nervous twitch. To cover expenses, he also took a large supply of sables, honey, salmon, and other smoked fish along with his personal drum. The embassy's purpose was to learn from the West and strengthen Russia's alliance against the Turks. Therefore, the Great Embassy didn't go to France, since it was allied with the Turks.

Because regular Russian embassies had no freedom of bargaining beyond the tsar's specific orders, negotiations with Russia took a long time and were not popular. One reason was that Russian ambassadors were required to demand that foreign monarchs receiving them should stand and remove their hats while inquiring about the tsar's health. Another problem was that Russian ambassador's were not paid, instead being given Russian commodities such as furs and honey to sell. This led to an international scandal in 1687 when Sophia's embassy to France smuggled furs into France and were caught trying to sell them.

The Great Embassy's first stop was in Riga Sweden with its modern fortifications, which Peter carefully studied, climbing all over them

and taking measurements. Since Peter was supposedly incognito, a Swedish guard arrested him as a spy. Although the incident was straightened out and Peter got out of the Swedish jail, he was angry about the whole incident and used it later as his pretext for war with Sweden.

Next stop was Prussia, which was interested in allying with Russia against Sweden. While there, Peter took lessons as a simple bombardier from a Prussian artillery officer. He also enjoyed dancing with the German ladies, although he was confused by their whalebone corsets, remarking: "*These German ladies have devilish hard bones.*"

After that, Peter moved on to Holland, where he put off the Dutch king, William III, by approaching him in his shirtsleeves. He was also extremely nervous in large groups of people, and news of the huge incognito tsar led to large crowds turning out to see him. As result, the Dutch put Peter up in a private building inside the Dutch E. India Company shipyards so he could be near his beloved ships.

Dutch shipbuilders had no blueprints, only rule of thumb techniques, which greatly disappointed Peter, since he had no plans or principles to take back for the Russians to follow. He did, however manage to entice 900 Dutch craftsmen to come to Russia to work. Before he left Holland after 8 months, the Dutch king delighted him with the gift of a sailboat (below) and a massive mock naval battle.

Peter found more than shipbuilding to interest him in Holland, notably anatomy and surgery, attending any classes, and operations he could. As a result, he considered himself a qualified surgeon with the surgical instruments for dissecting, bleeding, drawing teeth, and performing minor surgery. As with toothaches, it was dangerous to admit to any ailments

around Peter. He also expected the same level of interest in surgery among his followers. Therefore, when he saw his nobles' disgust while observing a dissection in surgery class, he got so mad that he ordered them to bend over the cadaver to sever the muscles with their bare teeth.

Another skill the Russians picked up in Holland was ice-skating. Unfortunately, several of them fell through the thin Dutch ice in warmer winter. However, instead of changing clothes, they just drank more.

Passing on to England, Peter got to spend more time building ships, setting off to the shipyards at 4AM every day with his ax slung over his shoulder and pipe in mouth. While there, Peter sold the tobacco monopoly in Russia to the British for £28,000, even though smoking tobacco brought the death penalty, or at least a slit nose, in Russia.

Peter was especially impressed with the British royal mint and was determined to adopt the minting of milled coins to prevent clipping. In turn, Europeans were impressed at how this tsar, who was barely literate, was so adept at mechanical things, even being able to take apart and reassemble clocks

Europeans were even more astonished at how Peter and his entourage could party. In particular, they trashed an English mansion where they were staying, tearing the doors off the hinges and using the owner's art collection for target practice. All fifty of the mansion's chairs were gone, probably thrown in the stove to make a fire. The featherbeds, pillows, and sheets ripped to shreds as if by wild animals or a rock band.

Even more entertaining was the "wheelbarrow game". Since there were no wheelbarrows in Russia, they didn't know what they were for when they found some in a shed. They quickly figured it out though, inventing a game where one Russian (often Peter himself) would push his team mate in a barrow at top speed and ram it into the owner's hedge, which was 400 feet long,

9 feet tall, and 5 feet thick—before the Russians invented their game.

Afterwards, the hedge was ruined.

Peter paid for the damages with a huge uncut diamond wrapped in a dirty piece of paper.

Peter by-passed France, since it was allied with his enemy, Turkey. However, he did return on a second embassy several years later, where he shocked the French by picking up the 8-year old crown prince and running upstairs with him, followed by a frantic crowd before the tsar did something like test the boy's aerodynamic qualities by tossing him out a window.

Peter's last stop was Austria, but he got there too late to stop it from making peace with Turks (i.e., the Treaty of Karlowitz). His visit there was cut short by news of a streltsy revolt. However, Peter and the Russian left behind years of gossip about these Russian barbarians with their massive drinking bouts, lechery, and ignorance of tableware.

Upon his return home, Peter dealt with the Streltsy revolt led by his sister Sophia. This time he disbanded the Streltsy, even executing five of them by his own hand. In their place he started building a new modern army, modeled, trained, and equipped like European forces.

Not being able to afford whole armies of mercenaries, Peter conscripted one recruit from every twenty households for a term 25 years, a virtual life sentence. As a result, the Russian army grew from 30,000 men in 1700) to over 200,000 men by 1725.

Similarly, Peter built up the Russian navy, which had 48 men-of-war, 800 smaller ships, and 28,000 men by 1705. However, he needed a saltwater outlet so he could use it. The Mediterranean was blocked by the Turks, but with the rest of Europe preoccupied with Louis XIV, he looked north for a port on the Baltic.

The Great Northern War (1700-21)

Also wanting to bring down Sweden, the rulers of Denmark, Saxony and Poland allied with

Russia to that purpose. Peter had previously supported Poland's King, Augustus, against a French candidate in order to keep Poland allied against the Turks, so they were natural allies and good friends.

Augustus (below left) was a man after Peter's heart, a wild practical joker who supposedly had fathered 354 children. He once gave Peter a gold box with a picture of one of his mistresses clothed on the front, while a secret spring revealed the same woman in a less modest posture. Another time, he brought the prudish Frederick William I of Prussia and his young son (the future Frederick the Great) into a bedroom to reveal a naked woman. Frederick William freaked out and fled with his son.

Peter's main opponent was Charles XII of Sweden (above right), only 18 years old at the time, but a military genius who had already reformed the Swedish army to incorporate the military developments of the last half-century, such as replacing the pike with the bayonet.

Charles was the last in the line of Swedish warrior kings, a great general who won unbelievable victories, but loved war and fighting to an obsessive degree. He seemed impervious to pain and the suffering of others, including his own men, in his relentless drive to win. When war broke out, he vowed to give up women, drink, and other pleasure until he had defeated his enemies. He kept his vow, even though he never won the war.

Charles quickly took Denmark out of the war by means of a daring crossing of a shallow part of the Danish Sound that threatened Copenhagen. The Danish king quickly signed a treaty, dropping out of the war.

Charles, with an army of only 8,000 men, next moved against Peter who had an army four times that size. At Narva (1700) a daring march during a blizzard through the swamps behind Peter split the Russian army and allowed the Swedes to demolish it. Although Peter (who was serving as a “lieutenant”) escaped, the rest of his army was killed or captured. The Swedes lost 667 men.

Luckily, Charles then turned on Poland and Saxony, defeated their forces and replaced Augustus with his own candidate. This gave Peter time to rebuild his army, even melting church bells for cannons. The climatic showdown came at Poltava.

In 1708 Charles crossed the Vistula River on unsafe ice with 44,000 men. Peter drew them in by a scorched earth policy that, combined with a fierce winter, cost the Swedes one-third of their infantry and their entire supply train.

The winter of 1708/9 was legendary in its ferocity. Supposedly:

- Firewood would not burn in open air
- The Baltic froze, allowing heavily laden wagons to cross it.
- Chickens’ combs froze solid and broke off.
- The canals of Venice froze, as did saliva before hitting the ground.
- Trees exploded from the extreme cold.

Charles’ troops took the cold stoically, many losing hands, feet, noses, ears, but still marching on, some even crawling. Somehow, Charles kept winning astounding victories, some against incredible odds. Then, on July 8, 1709, Charles and Peter met at Poltava.

Charles had been wounded in the foot before, fainting after taking the bullet out with his own knife. Even though he had to be carried in a litter, he still went into battle where his litter was

shattered by enemy fire. Peter, though only a “lieutenant”, led his troops into the thick of the fighting, one bullet passing through his hat and another only stopped by a cross around his neck.

At first, the Swedes carried the field, but years of training finally paid off for the Russians as they still held formation while keeping up a continuous rate of fire until the Swedes ran out of ammunition and a massacre ensued. Charles left the field with 1000 men, losing 4,000 killed and 18,600 captured. Poltava is generally considered a turning point for both Russia and Sweden, marking the end of Swedish imperial aspirations and the emergence of Russia as a major power.

Charles, however, was not through, gaining asylum in Turkey and training his remaining troops to renew the war. Therefore, Peter entered Turkey to get Charles, causing Turkey to declare war on Russia. An army of 200,000 Turks surrounded Peter, forcing him to surrender Azov and make peace with the Ottomans. However, Turkey’s treaty with Russia infuriated Charles, who made so much trouble that the vizier asked him to leave. Charles refused, and it took 12,000 Turks eight hours to storm his house and take him and his 40 Swedish comrades prisoner. Charles alone killed ten Turks and it took twelve Janissaries to carry him out.

Charles soon escaped and made a daring ride across Europe back to Sweden where he renewed the war effort, drafting 15-year olds and taxing everything he could think of, including wigs.

When he besieged in Stralsund by a large army, he fought heroically, leading futile sallies out of the walls. As the city was falling, he escaped through enemy fire to Sweden in a small boat.

By 1717 Charles had raised a new army of 20,000 men and invaded Norway to compensate for his mainland losses. The next year, while besieging Frederiksten, he raised his head over the parapet of the trench and was killed by a bullet to the temple. He was 36 years old. The debate continues whether it was a Norwegian or

assassin's bullet that killed him. After that Sweden tried to negotiate a peace to keep some of its East Baltic possessions, but three Russian invasions led to peace and a treaty in 1721 giving Russia Livonia, Estonia, Ingria, and parts of Finland.

St. Petersburg and other Reforms

Peter surveying his new capital, St. Petersburg

The Window to the West. St Petersburg, which symbolized the new direction Peter was forcing Russia to take, was founded in 1703 on or near the sight of another town, Neva, which in Swedish means "mud".

- During its construction, there was a law forbidding building with stone anywhere except at St. Petersburg.
- Summer daylight lasts from 3 AM to 10 PM; in winter from 9 AM to 3 PM
- Some 40,000 laborers were sent there each year, being paid only half a ruble a month, which led to rampant stealing.
- Thousands of Swedish prisoners died there from forced labor.

Nothing comes easily in Russian history.

The calendar. Peter changed the Russian calendar from starting at creation in September 5008 B.C.E. to starting at Christ's birth. Thus the old year 6708 became 1700. However, Peter's use of the Julian instead of the newer Gregorian calendar still threw the Russian calendar off 11 days in 1700's, 12 in 1800's, and 13 in the 1900's. That's why, according to the more modern Gregorian calendar, the so-called October Revolution in 1917 is observed in November.

Russian women. Peter tried to raise women's status, encouraging them to remove their veils, to

dance, make music, and get an education (by private tutors). Also, parents couldn't force women to marry against their wills.

Beard tax. Many Russians, especially the Old Believers, felt they had to keep their beards if they wanted to go to heaven. After all, why would God give us beards if he didn't mean for us to keep them? As a concession to that belief and a means to raise money, Peter let Russian men pay a special tax in order to keep their beards. Others, either too poor or unwilling to pay the tax, saved their whiskers to be buried with them when they died, feeling they couldn't get into heaven otherwise.

Peter's death. Peter died pretty much the way he lived. In November 1724 a ship ran aground in the Neva River. Peter, active as always, jumped into the river to save the sailors and the grounded vessel, working all night in icy waters up to his waist. As a result, he caught a fever that developed complications and he died on February 8, 1725. He was 56 years old.

THE DUTCH REPUBLIC IN THE 1600'S

An Extensive Landscape with a Road by a Ruin by Philips Koninck (1655)

Introduction. Although it took the Dutch until 1648 to force formal recognition of their independence from Spain, for all intents and purposes, the Dutch Republic was free by the twelve-year truce signed with Spain in 1609. The question arises: how did the Dutch hold off and defeat the biggest military power in Europe? While geographic distance from Spain, foreign aid from France and England, and the occasional desperate measure of opening their dikes to flood out invading armies all certainly played a role, the single most important factor was money. For example, of the 132 military companies in the Dutch army in 1600, only 17 were actually made up of Dutch soldiers. The rest were English (43), French (32), Scottish (20), Walloon (11), and German (9) companies fighting for the Dutch because they had the money to pay them. The war took a tremendous financial effort to win, costing the Dutch 960,000 florins in 1579, 5.5 million florins in 1599, and 18.8 million florins in 1640. Despite this expense, the Dutch were in stronger financial shape than ever by the end of the war and were well on their way to becoming the dominant commercial and economic power in Europe. This economic dominance was the product of a chain reaction of events and processes that, as so often was the case, was rooted in geography.

Geography of the Netherlands. Three geographic factors influenced the rise of the Dutch Republic. First, as the name Netherlands (literally "lowlands") implies, much of the Dutch Republic is below sea level. The Dutch have waged a constant battle in order to claim, reclaim, and preserve their lands from the sea through the construction of dikes, polders (drained lakes and bogs), drainage systems, and windmills (for pumping out water). Roughly

25% of present day Holland is land reclaimed from the sea and still partially protected by hundreds of windmills. The second factor is the Netherlands' position at the mouths of several major rivers and on the routes between the North Sea and Atlantic Ocean. The third factor is the Netherlands' relative scarcity of natural resources. All three of these factors forced the Dutch to be resourceful engineers, merchants, sailors, and artisans. With these geographic factors as a foundation, the Dutch launched themselves on a career that was a classic case of the old saying: it takes money to make money. The whole process started with fish.

In the 1400's, the herring shoals, a mainstay of the Hanseatic League, migrated from the Baltic to North Sea. The Hanseatic League's loss was the Dutch Republic's gain, since, in the absence of refrigeration, salted herring was then an important source of protein in Europe, especially the Netherlands whose population was 40% urban and had to import about 25% of its food. The other half of this trade was salt for preserving the herring. The best sources of salt were off the coasts of France (the Bay of Biscay) and Portugal. These two activities complemented each other well, since the herring season lasted from June to December, so the Dutch could collect salt from December to June.

The Dutch ran large scale operations compared to those of other countries. Unlike the simple open English fishing boats, the Dutch sailed virtual floating factories, called buses, with barrels of salt for curing the herring on board. Although the claims by other competing countries that the Dutch had 3000 ships working the herring shoals were vastly exaggerated (500 being closer to the mark), the Dutch still produced such a volume of salted herring that they could undersell their competition and drive them out of business.

The Dutch pattern of growth. Dutch control of the herring trade touched off a cycle where the Dutch would get profits, invest those profits in new ventures, which generated more profits and so on. This initially led into two general areas of development, foreign trade and the domestic economy, each of which fed back into the cycle of profits and so on. Both of these also led to expansion of trade across the globe to the Mediterranean, West Indies, Africa, East Indies, and

the South Pacific, which also fed back into the cycle of profits.

Concerning foreign trade, the Dutch first expanded their operations into the Baltic Sea where they traded for Norwegian timber, Polish grain, and Russian furs both to consume at home and sell abroad. The Baltic trade became so important that the Dutch referred to it as the "Mother Trade."

All this trade required durable, efficient, and cheaply built ships that could operate in the rough waters of the North and Baltic Seas as well as the shallow coastal waterways that were typical of the Netherlands. What the Dutch came up with was the *fluyt*, a marvel of Dutch efficiency and engineering. The fluyt was both sturdy enough to withstand rough seas and shallow enough for inland waterways. Unlike other countries' merchant ships, which doubled as warships, the fluyt carried few, if any, guns, leaving extra space for cargo. It was cheaper to build, costing little more than half as much as other ships, thanks to the use of mechanical cranes, wind-driven saws, and overall superior shipbuilding techniques.

A Dutch Fluyt

The fluyt also had simpler rigging that used winches and tackles, thus requiring a crew of only 10 men compared to 20-30 on other European ships. This resulted in two things. First of all, the Dutch could carry and sell goods for half the price their competition had to charge, giving them control of Europe's carrying trade. Second, they were able to dominate Europe's shipbuilding industry, which, of course, made them more money.

Meanwhile, the Dutch were developing their domestic economy in two ways. First they invested in a wide variety of industries, some traditional and some new: textiles, munitions, soap boiling, sugar refining, tobacco curing, glass, and diamond

cutting. The need for efficient handling of all the money from this and other enterprises spurred them to develop another aspect of their economy: financial institutions. For one thing, they established the Bank of Amsterdam in 1609, the first public bank in North-West Europe, being modeled after the Bank of Venice (f.1587). The vast sums of cash this bank attracted in deposits allowed it to lower interest rates, which in turn brought in more investments, and so on. Even in wartime, the Bank of Amsterdam was able to lower its interest rates from 12% to 4%. The Dutch also created a stock market. At first this was just a commodities market. Only later did it evolve into a futures commodities market where, by the time a shipload of such goods as wool or tobacco landed, someone had already bought it in the hope of reselling it for a profit.

The success of the Baltic Mother Trade and their domestic economy led the Dutch to expand their foreign trade on a global scale. They did this in three basic directions. First was the Mediterranean, where recurring famines hit in the 1590's, signaling the start of a "Little Ice Age" that would afflict Europe for the next century. This opened new markets for Polish grain, which the Dutch traded in return for, among other things, marble. (Louis XIV would buy this Italian marble from the Dutch for his palace at Versailles.) The Dutch even expanded this Mediterranean trade to include doing business with the Ottoman Turks. As the Dutch rebels had said back in the 1500s: "Better the Turk than the Pope."

Second, when Portugal (then under Spain's rule) closed access to its supplies of salt, the Dutch crossed the Atlantic to find salt in Venezuela. While in the Caribbean, they found that the plantations in the West Indies needed slaves, which got them involved in the African slave trade. While there, they also discovered an even more lucrative condiment than salt: sugar. Soon, the Dutch were founding their own colonies (e.g., Dutch Guiana) and sugar plantations and gaining control of the sugar trade. Soon, sugar was rivaling even the spices of the Far East in value. However, this is not to say the Dutch ignored the Far Eastern trade.

However, breaking into the lucrative Asian Spice market, the third new direction of Dutch expansion, was not so easy. For one thing, they had to find the

East Indies. Amazingly, the Portuguese had kept the South East Passage around Africa a secret for a full century since da Gama's epic voyage. The Dutch looked in vain for a northeast passage around Russia. They also sought a southwest passage, which Oliver van der Noort found (1599-1601), making him the third captain to circumnavigate the globe after Ferdinand Magellan and Sir Francis Drake. But that route was no more practical for the Dutch than it had been for the Spanish and English.

Finally, Jan van Linschoten, a Dutch captain who had served Portugal, showed the way around Africa in 1597. Although the first voyage was not a financial success, the second was, bringing back 600,000 pounds of pepper and 250,000 pounds of cloves worth 1.6 million florins, double the initial investment. Investors rushed to get in on the action, forming the Dutch East Indies Company in 1602. This privately owned company operated virtually as an independent state, seizing control of the spice trade from Portugal's weakening grip. From there, always in search of new markets, the Dutch explored the South Pacific, discovering Australia, New Zealand, and Tasmania, the last two names bearing evidence of their presence.

Such a far-flung trading empire required a navy to protect its merchant ships. Therefore, the Dutch developed such a navy, excelling in this as well as their other endeavors. At this point, warships generally followed the principle of the bigger the better. As a result, the man-of-war, as it was called, was a huge and bulky gun platform that did not suit the Dutch needs. For one thing, they needed more of a shallow-draught vessel that could sail in their home waters. They also needed a long-range ship that could protect their far-flung commercial interests. The result was the *frigate*, a sleeker shallow draught vessel with only about 40 guns, but capable of long-range voyages. Dutch frigates, along with their excellent sailors and captains, made the Dutch the supreme naval power of the early 1600's and also helped them dominate the warship-building industry, building navies for both sides in a Danish-Swedish war and for the French.

A cultural golden age. By the early 1600's, Amsterdam was the center of world trade, which allowed the Dutch to engage in one more type of activity: patronage of the arts. The seventeenth century saw the Dutch Republic become the center

of a cultural flowering much as Italy had been during its Renaissance. Along with money to patronize the arts and sciences, the Dutch Republic had both a free and tolerant atmosphere and enterprising spirit willing to challenge old notions and creatively expand the frontiers of the arts and sciences. The Dutch Republic acted as a virtual magnet for Jewish émigrés from Spain and Portugal and Calvinist dissidents from France, some of who would eventually move on to Plymouth Rock, Massachusetts. The Jewish philosopher from Spain, Spinoza, and the French mathematician, Descartes, were two of the shining lights that the Dutch attracted. Notable among Dutch artists were Rembrandt, Vermeer, Hals, Van Dyck, Steen, Ruysdael, and Hobbema, whose portraits, domestic scenes, landscapes, and mastery of light and shadow brought their age to life on the canvass as no artists before them had done.

Conclusion. The Golden Age of the Dutch Republic was to be short lived, once again largely because of geography. It was the Dutch Republic's great misfortune to border the great land power of the day, France. In the 1670's, the French king, Louis XIV, due to a combination of jealousy of Dutch prosperity and hatred of Protestants, launched a series of wars that would embroil most of Europe and put the Dutch constantly on the front line of battle. At the same time, just across the channel, the growing economic and naval power, England, was challenging the Dutch on the high seas and in the market place. Three brief but sharply fought naval wars plus the strain of fighting off Louis exhausted the Dutch and allowed England to become the premier economic, naval, and colonial power in the world by the 1700's. However, England owed the techniques and innovations for much of what it would accomplish in business and naval development to the Dutch from the previous century.

Windmills

“God created the world, but the Dutch created the Netherlands”

Windmills, although originally a Persian invention, revolutionized life and the very ability to live in the Netherlands. The windmills’ most vital task was protecting the low-lying Netherlands by pumping water up and back out to sea. In order to do this, the Dutch would construct a series of windmills, the first driving a waterwheel that scooped up the water and deposited it in a higher lock where the next windmill would move it to an even higher lock, and so on until the water had been raised to above sea level and could be deposited in the sea. After the initial labor invested in building the windmills, locks, and channels, everything else was done automatically and for free by the wind, which is plentiful in this flat land exposed to constant sea breezes.

Windmills (along with watermills and even tidal mills) performed a vast array of other jobs that involved sawing, grinding, pounding, and polishing. The most common day-to-day job was milling grain into flour. Doing this with a hand-powered stone mill was incredibly tedious, requiring several hours of hard work everyday to mill enough flour for one’s family. Thus taking one’s grain to mechanically driven mills was favored by anyone who could afford it.

The windmill itself was attached to a two-story structure that rested on a central hinge post. The miller could turn this structure to catch the wind at the best angle by picking up a long lever also attached to the structure. The miller then filled a hopper with grain leading down to and filling the spiral grooves cut into the bottom millstone on the second floor. Once set and the windmill sails were in place, the miller unblocked the windmill so the wind could turn it.

The drive shaft of the windmill then turned the top millstone and ground the grain in between it and the bottom millstone, turning it into finely ground flour that fell into a flour sack on the first floor. The miller’s assistant would bag up the flour for the customer, taking the miller’s cut, typically 20%...unless no one else was looking.

Exploding windmills. Critical to the safe operation of the windmill was keeping the hopper full of grain to avoid a flour dust explosion. As anyone knows who has ever dumped out a bag of flour, a good part of it flies back up into the air as flour dust. A full day of a windmill milling grain creates a thick cloud of flour dust. If the density of that cloud reaches a critical mass, any spark could detonate it and blow up the windmill in a devastating explosion (as still occasionally happens in grain silos).

Causing such a violent reaction was the grinding of the two millstones when exposed to the open air, which struck the spark to detonate the flour dust explosion. Keeping the hopper full of grain while the mill was turning was the key to keeping oxygen from reaching the millstones and making such a spark possible. There was a bell toward the bottom of the hopper that, when not covered with grain, would ring to remind the miller to refill the hopper or disengage the windmill before things got “blowed up real good.”

“Don’t fear the reaper. Fear the miller.” The way a medieval joke put it, a miller’s shirt was the bravest thing in the world because it held a thief by the collar everyday. (Keep in mind there were no professional joke writers back then.) Of course the question arises: how did millers rip people off? For one thing, they never let anyone up to the second floor of the mill to see what they were doing. What they were doing was sweeping extra grain and flour that had been thrown out of the hopper by the fast motion of the windmill (which could turn 50-60 miles per hour on a windy day). Legally, that extra grain and flour belonged to the customer, but since he was the only one up there, he would collect it as his extra profit margin.

The Sea is a Harsh Mistress

Ships in Distress off a Rocky Coast
(1667) by Ludolf Backhuysen

The relationship of the Dutch to the sea must have been especially ambivalent. On the one hand, it provided trade and resources from which to make a living. However, it was also a constant threat to the land itself as the Dutch worked tirelessly to protect old lands and reclaim new ones. In addition, sailing was a dangerous occupation, from both disease and storms. Dutch artists showed both aspects of the sea in their paintings: calm waters that brought prosperity and carried sailors safely home, and storms that threatened both. We even have a painting of the Schreierstoren (crying tower) where wives made their tearful farewells to sailors leaving Amsterdam.

Dredging rivers of silt was another aspect of the Netherlands' relationship to water in their never-ending process necessary to keep waterways open. This was especially an issue for the Dutch, since they were located at the mouths of several major rivers, which flatten out and slowdown as they approach the sea, dropping silt collected and carried from upriver. Dredging was done by human-powered paddleboats that worked their way upriver dragging stone slabs for scooping up and collecting silt. The silt itself could fetch a good price both for its fertility and as fill used in land reclamation.

Dutch Ships

Dutch shipbuilding. Dutch shipwrights used hull-first construction, heating the oak timbers over a fire to make them more elastic and then fitting them together. Only after the hull was completed did they add an interior frame to give it stability. While frame-first construction was

potentially better since it could be planned out in advance on paper, Dutch hull-first ships remained superior to other countries' frame-first ships at least until the 1700s.

This was largely because educated Renaissance ship designers seem to have relied too much on idealized perfect geometric shapes laid out on paper that weren't really that good for hull designs. Through trial and error, Dutch Shipwrights had learned that certain irregular lines in a hull actually made for better ships. Not until the 1700s was the technique developed for representing irregular shapes with lines like the contours on modern topographic maps, making it practical to design frame-first ships on paper that would translate into faster and sleeker ships.

Just pinch an inch. Such irregular lines could also solve other problems. For instance, Dutch ships had to pay a toll to go through the Danish Sound, the narrow strait between the North and Baltic Seas. Since the Danes estimated cargo space by just measuring the width of the beam at the center of the top deck, the Dutch built their fluyts in a pear shape, with the cargo space at the waterline bulging out and the top deck pinched in at the middle.

Block and tackle (AKA compound pulley) is a system of two or more pulleys with a rope or cable threaded between them to facilitate lifting heavy loads. Most likely it was invented by the Greek mathematician, Archimedes, in the third century B.C.E. The term *block* refers to all the pulleys, or *sheaves*, mounted on a single axle. The entire assembly of those pulleys with rope going through them is called a *tackle*. The most common arrangement is to have one block in a fixed position and another block hanging from it and moving with the load.

During the Dutch East Indies Company's existence 1,581 ships were built at its shipyards. The average lifespan of one of its ships was 15 to 20 years.

Fire pumps, which were a critical piece of equipment on wooden ships, underwent major

improvement with the introduction of Van der Heyden's hose that could pump the water all the way to the fire itself. Van der Heyden's device used a suction pump mechanism with a pressure tank to provide a continuous jet of water all the way to the fire's center.

The leather hose was reinforced inside with brass rings, keeping it flexible while ensuring the suction power wasn't cut. The hose could pump five to six times as much water as older pumps. The spouts and hose connections had standard screw attachments so every hose would fit every machine. It remained in use until the late 1800s.

Sugar and Tobacco

Sugar was the new taste sensation of early modern Europe, and the Dutch controlled much of its trade in the 1600s. Sugar cane was native to South and Southeast Asia where people originally chewed on it for its sweetness. When the process for granulating it was discovered, it became practical to transport sugar for trade. However, it remained a rare and expensive luxury, especially for Europeans, whose main sweetener was honey.

Columbus introduced sugar cane to the New World in 1492, and it became the primary agricultural export from the West Indies as sugar plantations appeared across the Caribbean. However, harvesting and processing it was very labor intensive, made even worse by the Caribbean's tropical climate. First, and possibly worst, was cutting the sugar cane. After that, it was carted to the mill, where it was run through rollers to squeeze out the juice. Then it had to be boiled down to crystals, which were loaded in bags and shipped off to Europe.

The large amount of hard work required to process sugar cane had its tragic side, namely the African slave trade needed to provide the labor force needed on the plantations. Making matters worse was the fact that conditions (both natural and man-made) were so bad that slaves died off faster than they could reproduce, thus prolonging the slave trade for centuries. In fact, the only place where slaves were able to sustain

their numbers through natural increase was in the British colonies of North America.

Tobacco was another popular sensation in Europe at that time. By 1718 there were at least 73 tobacco shops in Amsterdam. One principal branch of the industry was processing leaves into snuff and tobacco for smoking. This took place in workshops known as tobacco spinneries, of which there were about 30 in Amsterdam in 1730.

Tobacco use was particularly popular among sailors. Officers for the Dutch East Indies Company were each allowed to take up to 30 pounds of tobacco for their own use on a voyage to Asia, and it was probably part of the rations allocated to the crew of a Company ship. Because of the danger of fire, tobacco could only be smoked on board during the day, "*with the consent and knowledge of the captain, skipper, or Commander, and that only in the boarding nets and fore the mainmast....*" Anyone failing to keep to this strict rule would forfeit a month's salary.

Snuff was a smokeless tobacco, oftentimes scented, that was sniffed directly into the nose. It was especially popular in the 1600s and 1700s among the rich, and has recently experienced resurgence as tobacco smoking has been banned in more and more places.

Columbus' men first encountered snuff use among natives in Haiti. It gained popularity at the French court of Catherine de Medici in the 1500s as a cure for her son's migraines, and its use spread from there. There were opponents, such as Pope Urban VIII who threatened to excommunicate tobacco users. In Russia, Tsar Michael I set the punishment for snuff use as the removal of one's nose. Nevertheless, its use spread among European royalty, especially Louis XIII of France, and from there to the nobles and rich middle class. It was also supposedly spreading to China by 1640.

Being smokeless, snuff doesn't expose its users lungs to tar and harmful gases such as carbon monoxide. But it still runs the risk of localized cancers where it is applied (e.g., nose and

mouth). As early as the 1700s, a British doctor, John Hill, was warning of the dangers of nasal cancer from snuff use.

The crew and chain of command on Dutch East India Company ships

In theory, the senior merchant held supreme power on company ships, but in reality the shipmaster took over when trade was no longer taking place. The chain of command under him along with their duties went as follows:

- *The chief boatswain* (hogboatsman), roughly equal to a petty officer, supervised whole crew.
- *The boatswain* was responsible for running and standing the rigging, especially for the mainmast.
- *The rigger* watched the foremast sails.
- *The helmsman* also supervised stowage of goods and ship maintenance.
- The steward distributed weekly rations of food and drink for all on board and also supplied the cook with victuals .
- The marshal was in charge of order and discipline.

The ship's company, who made up the bulk of the crew, was divided into three groups or watches, creating a steady rhythm of six four-hour watches each day. Changing the watch was signaled by a drum.

During the Dutch East Indies Company's existence, less than 3% of all its ships sailing from Europe to Asia were lost, either through misfortune or enemy action. For homeward bound ships it was less than 5% .

Heavily armed spice fleet returning to Amsterdam

Severe punishments were considered necessary to keep order among such an unruly group as sailors. For example, pulling a knife in anger led to the offender being nailed to the mast with a knife through his hand, and he had to remain standing there until he pulled his hand off.

Dutch naval officers. Unlike their French and Spanish counterparts who were nobles that saw their positions as a birthright, Dutch officers worked their way up the chain of command, starting as ships' boys around the age of 12. By the time they became captains, they were intimately acquainted with just about every aspect of running a ship.

Take, for example, Admiral Michiel de Ruyter (1607-76), or as he was known to his sailors, Grandpa, one of the Dutch Republic's greatest naval commanders. After one battle, he shocked his French allies by sweeping the broken glass out of his own quarters and feeding his chickens.

Amsterdam :“Venice of the North”

By 1600, Amsterdam had largely replaced Antwerp as the premier trading center of Europe. Amsterdam was located where the Amstel & Ij Rivers flowed into the Zuider Zee. Since it was on marshy ground, the city was built on a system of piles in five concentric rings of canals, creating a virtual archipelago of 70 islands linked by 500 bridges arching high to let boats through. As a result, Amsterdam was dubbed the "Venice of the North". Its city hall alone rested on 13,659 piles, the Dutch calling it the Eighth Wonder of World. Its fortifications

were built inside the outermost canal, which then doubled as a moat. The practical Dutch, not wanting to waste any space, built windmills on their towers to pump out water.

Dutch frugality and the limited space of Amsterdam's urban environment led to very narrow red brick houses since they were taxed on the basis of width. Oftentimes, a beam projected out over the street from the second story of a house to haul heavy furniture up since it was too wide for front doors.

Although Amsterdam was the real economic and cultural center of the Dutch Republic, the Hague was the political capital.

Baroque art

Just as the Italians largely defined art for Western Europe in the fifteenth and sixteenth centuries, the Dutch did much the same during the seventeenth century, although art flourished across the continent. The art of this period is typically referred to as Baroque, a term originally meaning twisted or distorted. However, in this context, it also implied dramatic, even chaotic, motion as well.

Baroque was largely an outgrowth of a movement called Mannerism that started in Italy in the latter half of the 1500s. Having achieved such technical proficiency in Renaissance art with its rational and harmonious composition, Italian artists were anxious to try something new. The result was a style of art that replaced reason with emotion, harmony with dissonance, reality with imagination, and equilibrium with instability. Mannerist paintings might leave a void in the center of the canvas while figures crowded around and were even cut off at the edges of the painting. Their figures were often writhing and twisting with bodies that were elongated or grossly muscular. They also might use lurid colors and unreal lighting to create a heightened impression of tension and motion. Probably the most famous practitioner of this style was El Greco in Spain.

While Baroque artists incorporated Mannerism's elements of dramatic motion and

tension, they kept to the more realistic perspective and proportion pioneered by Renaissance artists. Baroque artists, in particular the Dutch, might create tension in otherwise placid scenes through relatively innocuous elements in a painting, such as dramatic cloud formations. Many of them were also masters of light and shadow, which they used to dramatic effect.

Michelangelo Caravaggio (1571-1610) was to a large extent the father of Baroque, breathing new life into Italian art after the sterile artificiality of Mannerism. Disdainful of artistic convention & tradition, he painted saints as ordinary people and miracles as events often set in seamy slums, pubs (*The Calling of St. Matthew*), or wine shops (*Supper at Emmaeus*). Many thought he went especially too far when he used a drowned corpse with bare feet and swollen body for *The Death of the Virgin*.

Caravaggio's use of dark backgrounds and harsh single sources of light focused viewers' attention on the main subject and/or events. His *Conversion of St. Paul* (below) shows the saint fallen from his horse with a rear view light illuminating mundane details such as the veins in his legs and rivets on his armor.

In his painting, *Amor Victorious*, he portrays Cupid as mischievous, if not somewhat evil, and shows wrecked musical instruments in the background to symbolize how love disrupts the harmony in our lives. In his portrayal of *Bacchus* (below right) he shows the god of wine and revelry as dissipated, thus paying the price of his party lifestyle.

Caravaggio's life was as unconventional as his art. He was constantly brawling in pubs and fleeing from city to city to avoid the law. Once he

even stabbed a man in the groin over a tennis wager. Enemies called him the "anti-Christ of painting" and many patrons refused to accept his work as too vulgar and profane. But his use of lower-class folk in religious paintings expressed the Counter-Reformation's belief that faith was open to all. Caravaggio Influenced artists like Rubens, Velasquez, and Rembrandt by showing how to give paintings an overwhelming immediacy.

Gian Lorenzo Bernini (1647-1652). What Caravaggio did for Baroque painting Bernini did for sculpture and even more, since no other sculptor of the age could even compare to him. More than any other sculptor, including Michelangelo, Bernini could make the stone seem to come to life with vibrant dramatic motion as in *Apollo and Daphne* (below). He was also an accomplished architect, his most notable achievement in that field being the colonnade embracing St. Peter's Square in Rome, the intended effect being to make pilgrims feel enfolded in the arms of the Church. Bernini also adorned Rome with several spectacular fountains.

Diego Velazquez (1599-1660) and the Spanish Baroque. While Spain has not usually been at the center of Europe's cultural movements, it has generally produced one or two outstanding artists each century: El Greco in the late 1500s, Velasquez in the 1600s, Goya in the 1800s and Picasso and Dali in the 1900s.

Velasquez was very precocious, being qualified as a master by age 18. While in Madrid, he did a portrait so perfect it caught the attention of Philip IV who declared Velasquez as the only

painter to do his portrait. He would remain the official court painter for thirty years.

Velasquez' paintings were masterpieces of realism, but used no visible outlines, creating forms with fluid brushstrokes and applying spots of light and color. In a sense, he was a precursor of Impressionism two centuries later. Whether painting the king or a court dwarf, he showed them with humanity and dignity, using natural poses without gaudy accessories. He preferred understatement to ostentation, and realism to idealism.

His portrait of Pope Innocent X (belowleft)was possibly his finest portrait showing him with a sharp glance so lifelike and even predatory that Innocent himself declared it "troppo vero" (very truthful).

Velasquez' *Las Meninas* (above right) was voted in 1985 by a poll of artists, and by considerable margin at that, as the world's greatest painting. Ostensibly it is a painting of the five-year old princess, Margarita, with her ladies in waiting (*meninas*) and two dwarfs. Therefore, it is like a group portrait on the theme of a visit to the artist's studio. In the middle is the mirrored reflection of the king and queen, while to the left is a self-portrait of the artist painting this scene from a mirror. Although the figures seem informally grouped, the painting actually consists of a carefully balanced series of overlapping triangles. Only the lower half of the canvas has portraits, with the rest filled by a range of light and shadow, giving the illusion of space. One contemporary exclaimed that while others' work was art, Velazquez' alone was truth.

Sir Peter Paul Reubens (1577-1640) was the epitome and spirit of the Flemish Baroque. Since

the Spanish Netherlands remained Catholic, it produced more religious paintings than did artists in the Protestant North. Reubens was truly a European rather than a Flemish figure and painter, going to courts in Italy, France, Spain, and England, as both a painter and diplomat. As a result, his work synthesized the styles and concepts of Catholic and Protestant Europe. He was called "a prince of painters and a painter of princes", being multi-talented, classically educated, fluent in six languages, handsome, vigorous, and well traveled.

Reubens had seemingly inexhaustible stamina, rising at 4AM and working nonstop until evening. His studio in Antwerp was open to visitors and had a balcony he designed so customers could watch him paint huge his huge paintings. It was compared to a factory where he did small color sketches in oil or outlined work in full size to be painted by his assistants and finished by him. Supposedly he would stare at a blank canvas with his arms crossed, then suddenly explode into a flurry of quick brushstrokes covering canvas. In the process he completed 2,000 paintings, which is an accomplishment only surpassed by Picasso. A visitor recalled visiting his studio while Reubens painted, listened to Ovid in Latin, carried on a learned conversation with someone else, and dictated letter, all at once.

Reubens is probably best remembered for his full-bodied sensual nudes. Even today we refer to such a body type as *rubenesque*. It is also an excellent reminder of how standards of beauty have differed from time to time and from culture to culture.

Reubens, *The Three Graces*

Reubens himself was happily married to two women, the second only sixteen years old. Both embodied his ideal of feminine beauty: buxom, plump, smiling with golden hair and luminous skin, which was especially tricky to paint. His promise to customers of "many beautiful nudes" was a big selling point. Unlike most artists who worked in the classical style from plaster or antique sculptures, Rubens preferred to sketch live models.

Among his most famous paintings was the Marie de Medici series, commissioned to immortalize the life of Louis XIII's mother in 21 large painting. Totally undaunted, he exclaimed: "*My talent is such that no undertaking, however vast in size...has ever surpassed my courage.*" True to his boast, he finished the 21 large-scale paintings in three years (1622-25), largely because he made extensive use of his apprentices to do a lot of the work on paintings while he did the finishing touches and signed them.

Creating epics out of such inglorious and petty subject matter, he portrayed Marie giving birth as a solemn nativity scene, her education being overseen by the Greek deities Hera, Aphrodite, Athena, and Apollo. He showed Marie's arrival at Marseilles as epic pomp, diplomatically omitting her double chin, although later paintings did portray her queen-size corpulence. *Sir Anthony Van Dyck (1599-1641)* was the other big name in Flemish art. A child prodigy, he was an accomplished painter by age 16 and worked with Rubens for a few years in Antwerp. However, not content to act as second fiddle, he went to Italy and then to England as the court artist for Charles I. Handsome, vain, and addicted to high society, he was something of a snobbish dandy who strutted around with a sword and adopted the sunflower as his personal symbol.

He was popular as an artist, because he painted the ratio of the head to the body as 1:7 rather than the usual 1:6, making his subjects seem taller and more slender and producing more flattering portraits. The ease of composition and sense of arrested motion with which he painted his subjects made them seem as if they were pausing rather than posing, giving a natural realism to an otherwise stilted scene. Most notably, he portrayed the stubby and plain Charles I (below) as a dashing and warlike king.

The Dutch Baroque (fl.1610-1670). Two things made the Dutch Baroque unique. For one thing, Holland was a Protestant country, so there was no Catholic Church to commission the creation of huge paintings. On the other hand, Holland was very rich, with a wider distribution of wealth, thus creating a larger market of moderately affluent consumers, people like butchers, bakers and craftsmen. This, in turn, helped support some 500 artists who could specialize in certain genres of painting: landscapes, still-lives, architecture, home interiors, etc., the sorts of mundane subjects their customers were more interested in, thus providing us with remarkable details concerning the daily lives of the Dutch. These artists were known as the little masters, because their customers could only afford small paintings.

What made the Dutch excel was their ability to capture the play of light on different surfaces and suggest textures from matte to luminous. Three artists especially stood out among the Dutch: Rembrandt van Rijn, Franz Hals and Johannes Vermeer.

Franz Hals (1580-1666) specialized in portraits, in particular of men and women caught in moments of rollicking high spirits. These informal poses brought his subjects to life, capturing a moment in time as well as a face. Much of this was the result of his technique of "alla prima" (at first), where he applied paint directly to the canvas without an undercoat, completing a painting with a single application of brushstrokes, thus capturing the immediacy of the moment.

The Jester and The Drunkard by Franz Hals

Johannes Vermeer (1632-75) is best remembered for his interiors and mastery of light and is now considered only second to Rembrandt among Dutch artists. Only 35 to 40 of his paintings survive, partly because he worked so deliberately and partly because he died at a fairly young age.

Perhaps only Van Eyck was as skillful as Vermeer in his masterful use of light. While most artists used a gray/green/brown palette, Vermeer's colors were brighter, purer, and glowed with greater intensity. He also used dabs and points of paint that would reflect more light, so his paint surface has been described as being like "crushed pearls melted together". Vermeer was also a master of varying the intensity of an object's color in relation to its distance from the source of light. He achieved serenity and stability through subtly balanced compositions. For example, he avoided monotony in *The Kitchen Maid* by putting stains, holes, and a nail in the walls.

Left: Jan Vermeer (1632-75), *View of Delft*, ranked by an art critics' poll as the 2nd best painting ever. Right: *The Kitchen Maid*

Rembrandt Van Rijn (1606-1669) may be the best-known painter in the Western world. It's almost as if he were two artists, since his career breaks down into two very distinct styles. For the first 20 years of his career when his paintings

were at the height of fashion, his art was intricately painted and dramatically lit.

One of his most famous paintings, *The Nightwatch*, shows his technical skill with light, composition, and color. Its title, which was given later by the way, is misleading because the dark varnish coating it gives the false impression it was at night. Like Hals' work, this painting revolutionized the group portrait. Instead of showing stiff orderly rows of men, it captured a lively moment of communal action along with a sense of hectic motion through the Baroque use of light and movement. The captain and lieutenant seem to step into the viewer's space while flashes of light contrasting with the dark background keep the eye zigzagging around the picture. Crisscrossing diagonals of pikes, lances, rifles, and the flag make the scene appear chaotic, but since they converge at rt. Angles, there is a hidden geometric pattern holding everything together. Color harmonies of the yellow in the captain's uniform with the girl's dress and of the red sash with the uniforms of two others in the painting also unify the design.

Supposedly each member of the company paid equally to have himself painted, so Rembrandt's obscuring some of the sitters' faces made them angry and marked the decline of his popularity

The turning point in styles came in 1642, the year of the completion of *Nightwatch* and also when his beloved wife died (having already lost

three infants). After this, Rembrandt's art (such as *Landscape with Mill* (above) exhibited a quieter, deeper style that was less physical and more psychological. He turned more to biblical scenes, and painted with more restraint, his paintings dominated by reds and browns, broad brushstrokes, solitary figures, and a feeling of loneliness.

In addition to painting, Rembrandt was also an accomplished etcher, handling a needle with such skill and speed that his work seemed to have the spontaneity of a sketch. One etching, "Six's Bridge", was a landscape, supposedly "done between courses of a dinner while waiting for a servant to fetch some mustard from a nearby village.

Rembrandt painted nearly 100 self-portraits over his career of 40 years, ranging from the vitality and optimism of his youth to the physical decay and loneliness of old age, a visual chronicle of his life that remained unparalleled until van Gogh did much the same over two centuries later.

THE “TULIPMANIA” OF THE 1630s

Hans Bolliongier, *Still Life with Flowers*, 1639. Because of their rare beauty, tulips became the subject of a number of still-life paintings by Dutch artists.

There are few things more resilient than greed, as seen by the succession of “boom and bust” speculative markets in the modern era over such things as stocks in the 1920s, dot.com’s in the 1990s, and real estate in the 2000s. The grand daddy of all these speculative markets took place in Holland in the 1630s and focused on, of all things, tulips.

The tulip seems to have originated in the harsh wind-blown environment of the Himalayas. It was originally a short, stubby flower, but was admired for its beauty and as a symbol of the tenacity of life. Tulips spread westward and became especially popular among the Arabs who cultivated gardens of them. Their popularity spread to the Turks, Suleiman the Magnificent even having a tattoo of a tulip to serve as a protective talisman.

The tulip first arrived in Antwerp in 1562 by way of trade with the Turks. By this time, the influx of money from the Americas and expanding trade routes were pushing rich Europeans to look for new ways to spend and invest their money. One area was botany and gardening, thanks largely to the circulation of new scientific knowledge by the printing press. This and two other factors made the tulip seem like a lucrative investment. One was that it was difficult for many Dutch artisans at the time to make a profit, so they were also looking for another source of income requiring little capital investment. The other factor was that tulips reproduce slowly, thus creating a limited supply that could be sold for a high profit.

At first, the tulip trade grew at a reasonable rate, as demand for this new sensation grew while the supply remained constant, thus driving prices up. This would draw more people into the speculative market, further increasing demand, driving prices up more, and so on. However, what started as a somewhat rational trend soon turned into a frenzy of buying and selling, with each new buyer expecting to be able to sell at a higher price. People were paying outrageous prices, such as plots of land, a whole trade ship, and, in one case, an entire mansion, for a single bulb. They were also borrowing heavily and going into debt to buy tulip bulbs, counting on future profits from other people caught up in the same frenzy.

Unfortunately, a major problem with tulip bulbs was the fact that the most beautiful designs in tulips tend to be recessive traits, so there was no guarantee that a tulip bulb’s offspring would have the same traits as its parent. Eventually, as people realizing this and saw that tulips were extremely over-priced, the seller’s market turned into a buyer’s market. Unfortunately, there were no buyers, so prices dropped rapidly. This led to panic selling, since so many people were in debt for tulip bulbs they hoped to sell, driving prices down more, leading to more panic selling, and so on. By the end of 1637, the tulip bubble had burst and “tulipmania had collapsed as suddenly as it had bloomed.

Even though the speculative bubble popped, tulips regained much of their value. Louis XIV would buy 2,000,000 tulips a year from the Dutch for his palace at Versailles. They continue to be a major export for Holland (the Dutch Republic).

Tulip Fun Facts

The first tulip bulbs to arrive in Antwerp in 1562 were mistaken for onions, so most of them were chopped up and eaten.

The word tulip comes from *tulipan*, a corruption of the Turkish word *dulband*, meaning turban, because of their shape.

In Rembrandt's famous painting, *The Anatomy Lecture-of Dr Nicolaes Tulp* (above), the doctor's original name was Claes Pieterzoon, but he had his name changed to Tulp (tulip) to show his love of the flower.

Although people in the 1600s did not realize it, the most beautiful and sought after designs in tulips, such as the Semper Augustus shown here, are the results of a virus. At one auction in 1637, one bulb cost 5200 guilders, at a time when a university professor's annual salary was 1200 guilders.

A single Viceroy tulip bulb was traded for four fat oxen, eight fat pigs, twelve fat sheep, four loads of rye, four barrels of eight-florin beer, two loads of wheat, two hogsheads of wine, two barrels of butter... one thousand pounds of cheese, a complete bed, a suit of clothes and a silver beaker, worth a total of 2,500 florins.

To top that, one Semper Augustus bulb, an even rarer variety which was very rare during those times (so rare that only two horticulturists in Holland currently carry them,) brought twice that sum, plus a new carriage to boot. Another one was traded for an entire brewery.

Today Holland annually produces three billion tulips, one billion for domestic use and another billion going to the United States.

Tulips are only available from November to May and have a life span of just 3-7 days.

LAYING THE FOUNDATIONS FOR ABSOLUTISM IN FRANCE AND EUROPE

Henry IV (1598-1610). As we have seen, a major outcome of the French Wars of Religion (1562-98) was the willingness of the French people to recognize the king's power in order to ensure the peace. The new king, Henry IV (1598-1610), and his minister, Sully, used this new attitude favoring absolutism and various economic measures to restore the power of the monarchy. First of all, they repudiated all foreign debts, while repaying French creditors at a much lower rate of interest. Second, they established the *Paulette*, a tax on hereditary offices that would partially make up for lost revenues when commoners bought such offices. Third, they practiced a new economic theory called mercantilism.

Mercantilism was the dominant economic theory of the 1600s and 1700s, seeing gold & silver as the sole measures of a society's wealth. Therefore, to cut imports and raise exports the state should develop and support industries, roads, merchant marine, colonies, etc. Given the limited consumer market back then, states especially promoted luxury industries, such as silk and tapestries, to compete with foreign industries.

Mercantilism was a mixture of good news and bad news. It was good in the sense that kings were showing increased interest in their states' economies by developing roads, industries, etc. On the other hand, it could be bad when kings showed *too much* interest in their states' economies by exercising too heavy-handed control that stifled initiative and cut productivity. Overall, by the end of Henry's reign, the royal government was probably as financially solid as it had ever been.

Louis XIII (1610-43) and his minister, Cardinal Richelieu, continued building royal power. They particularly focused on breaking the nobles' power by destroying their castles, quickly crushing any of their conspiracies, and infringing on their privileges (such as dueling). They also excluded them from royal councils, using more reliable middle class officials. In 1634 Richelieu also created two new institutions with which to make the nobles increasingly obsolete: *generalites* and *intendants*.

Generalites were the 32 non-feudal provinces designed to undercut the authority of the old feudal provinces and their noble officials. Since the boundaries of the *generalites* partially overlapped with but did not totally conform to those of the old feudal provinces, disputes over jurisdiction between the two types of provinces were inevitable. This

could be especially useful for any disputes between two parties from different feudal provinces but the same *generalites*.

Intendants were the main royal officials Richelieu placed in every one of the *generalites* in 1634. At first their job was mainly to report corruption and make sure the tax farmers got their money. Naturally, both the financiers and *intendants* were quite unpopular, getting them involved in numerous court disputes. However, since the *intendants* were new *royal* officials with no tradition of being tried in local or Church courts, all their cases went to the royal courts, which naturally favored them as representing the king's interests.

Eventually, Richelieu expanded the *intendants'* duties to include supervising justice and tax collection, getting recruits for the army, and regulating commerce, trade, the guilds, and other financial activities. They also transmitted messages directly between local authorities and the king, to whom they were solely responsible. This neatly sidestepped the firmly entrenched interests of local authorities and laid the foundations for more thorough royal control of the provinces and France under Louis XIV, making them the most reliable element in royal government until the French Revolution in 1789.

Sully, Richelieu and Intendants

During the 17th century, it was common for rulers to appoint ministers to run the affairs of state for them, such as Count Olivares for Spain and Oxenstierna for Sweden. For Henry IV of France, it was Maximilien de Béthune, Duke of Sully (1560-1641). Sully favored indirect taxes, such as sales taxes, the *gabelle* (a salt tax), and tolls, which everyone (i.e., even nobles and clergy) had to pay. He also instituted the *Paulette*, an annual tax worth one sixtieth of the original price of an office. Paying it made the office hereditary so one could pass it on to his heirs.

Sully also started a nationwide highway system to facilitate trade. Thanks to Sully's stringent financial measures, Henry IV had a huge surplus in his treasury by his death. Sully even wanted to establish what he called the Great Design, an international body of all Christian rulers to help guarantee the peace, although he attributed the design to Henry IV. Sully resigned as minister in 1611, soon after Henry's assassination.

The next truly prominent minister for France was Armand Jean du Plessis, cardinal-duc de Richelieu (1585-1642). As the third son of a somewhat impoverished noble, he had limited prospects for a career. But he made the most of those opportunities through hard work, rising up in the ranks of the Church to bishop of Lucon at age twenty-one (for which he had to get a special papal dispensation, since the minimum age for a bishop was supposedly twenty-six.)

When Henry IV was assassinated and Marie de Medici became regent for her nine-year old son, Louis XIII, Richelieu attached his fortunes to Marie's advisor, an Italian named Concini. However, Concini proved to be very unpopular, especially with the young king, who had him arrested and killed. Deprived of his patron, Richelieu skillfully managed reconciliation between Louis and Marie and worked his way back to a position of influence.

In 1624 he commanded a royal army against the Protestant Huguenots, besieging their main city, Rochelle (above), for 14 months before it finally surrendered with its population reduced by fighting, hunger, and disease from 27,000 down

to 5,000. Although the Huguenots kept their religious freedom according to Henry IV's Edict of Nantes, their power was broken as they were deprived of their political liberties and fortified towns.

In 1630 Marie de Medici's jealousy of Richelieu's influence led to her downfall in what became known as the Day of the Dupes. Sure of her influence over her son, she demanded that he choose between her and the cardinal as his minister. To her surprise, Louis chose Richelieu and Marie was effectively exiled from the court.

Richelieu had two main goals for his king and France. One was to break the Hapsburgs' power, which seemed even more threatening by 1634 after defeating the Bohemians, the Danes, and the Swedes in the Thirty Years War. Despite being a Catholic cardinal, Richelieu allied with various Protestant princes against the Catholic Hapsburgs, eventually wearing them out, although at great expense for France as well. This helped set up French dominance of the continent by Louis XIV twenty years later.

His second goal was to build up the king's power at the expense of the nobles. To that end, he destroyed their castles, kept them out of royal councils, and instituted a new administrative system for France: the *generalites* (below).

Generalites were the 32 non-feudal provinces designed to undercut the authority of the old feudal provinces and their noble officials. Since the boundaries of the generalites partially overlapped with but did not totally conform to those of the old feudal provinces, disputes over jurisdiction between the two types of provinces were inevitable. This was especially useful for any disputes between two parties from different feudal provinces but the same generalites.

Intendants were the main royal officials Richelieu placed in every one of the generalites in 1634. At first their job was mainly financial, including keeping an eye on the tax farmers, but it quickly expanded to include supervising tax collection, supervising the courts, getting recruits for the army, and regulating commerce, trade, the guilds, and other financial activities. They also transmitted messages directly between local authorities and the king, to whom they were solely responsible.

Intendants were appointed directly by the king and were generally drawn from former middle class subjects who had recently bought their way into the Nobility of the Robe, thus being more loyal to and dependent on the crown. They were never assigned to their home provinces, where they might have an independently established power base. However, intendants tended to stay in the same province for long periods of time, sometimes decades. As a result they could get to know local conditions and people and provide more responsible and responsive government, especially since they answered directly to the king.

Marie de Medici commissioned Peter Paul Rubens to do a series of no fewer than 21 giant paintings commemorating her life. He finished the entire project in three years, largely through extensive use of his apprentices to do a lot of the work on paintings while he did the finishing touches and signed them.

Left to right: *Fates Spinning the Threads of Marie de Medici's Destiny*; *The Birth of Marie de Medici*; and *The Arrival of Marie de Medici in Lyons*

Rubens, *Henry IV viewing A Portrait of Marie de Medici*. Since kings often did not meet the foreign princesses they were to marry until the wedding day (or after if they were married by proxy), they might have an artist do a portrait of the prospective brides for a sneak peak before choosing the lucky lady.

THE AGE OF LOUIS XIV, THE "SUN KING" (1643-1715)

"I am the state."-- Voltaire incorrectly quoting Louis XIV

Introduction. From 1643 to 1815 France dominated much of Europe's political history and culture. Foreigners came to France, preferring it to the charms of their own homeland. Even today, many still consider it *the* place to visit in Europe and the world. In the 1600's and 1700's there was a good reason for this dominance: population. France had 23,000,000 people in a strongly unified state compared to 5,000,000 in Spain and England, and 2,000,000 in the Dutch Republic and the largest of the German states. This reservoir of humanity first reached for and nearly attained the dominance of Europe under Louis XIV, the "Sun King".

Louis' early life and reign (1643-61). Louis was born in 1638 and succeeded his father, Louis XIII, as king in 1643 at the age of five. Luckily, another able minister and Richelieu's successor, Cardinal Mazarin, continued to run the government. In 1648, encroachment by the government on the nobles' power, poor harvests, high taxes, and unemployed mercenaries plundering the countryside after the Thirty Years War led to a serious revolt known as the Fronde, named after the slingshot used by French boys. Louis and the court barely escaped from Paris with their lives. Although Mazarin and his allies crushed the rebels after five hard years of fighting (1648-53), Louis never forgot the fear and humiliation of having to run from the Parisian mob and fight for his life and throne against the nobles. This bitter experience would heavily influence Louis' policies when he ruled on his own.

From 1643 to 1661, Cardinal Mazarin ruled ably in the young king's interests, although he provided Louis with a rather odd upbringing for a king. Despite an immense fortune, Mazarin was something of a miser who gave the young king inadequate food, clothing, and attention. (Once the young Louis was left unattended and fell into a fountain where he almost drowned.) Louis also got little in the way of a formal education and, even as an adult, was barely literate. But Mazarin did give Louis a sense of what it meant to be a king. As a result, he turned out to be a hard working ruler, but often lacked much common sense and the willingness to entrust enough freedom of action to his subordinates. From his mother, a full-blooded Spanish princess, Louis learned great religious piety and love of ritual, another trait that would influence his reign. In 1661, Mazarin died. Louis' officials, assuming he would be a "do nothing" king like his father, asked to whom they should now answer. Louis' reply was "To me." The age of Louis XIV was about to begin in earnest.

Louis' internal policies. Louis XIV may not have said, "I am the state", but he ruled as if he had said it. Louis was the supreme example of the absolute monarch, and other rulers in Europe could do no better than follow his example. Although Louis wished to be remembered as a great conqueror, his first decade of active rule was largely taken up with building France's internal strength. There are two main areas of Louis' rule we will look at here: finances and the army.

Louis' finance minister, Jean Baptiste Colbert, was an astute businessman of modest lineage, being the son of a draper. Colbert's goal was to build France's industries and reduce foreign imports. This seventeenth century policy where a country tried to export more goods and import more gold and silver was known as *mercantilism*. While its purpose was to generate revenue for the king, it also showed the growing power of the emerging nation state. Colbert declared his intention to reform the whole financial structure of the French state, and he did succeed in reducing the royal debt by cutting down on the number of tax farms he sold and freeing royal lands from mortgage. Colbert especially concentrated on developing France's economy in three ways.

First of all, Colbert concentrated on developing French internal trade in order to reduce foreign imports. He developed better inland trade routes by building canals and improving ports and river ways, which would connect different parts of the country to each other and open up new markets. Secondly, Colbert worked to develop French industries. Most industries he developed can be seen as being aimed against imports from other countries: mirrors from Venice, lace from England, and iron and firearms from Sweden. He also built a merchant marine to stop foreign powers, especially the Dutch, from carrying French goods and making profits at France's expense. In 1661, France had a merchant marine of 18 ships. By 1681, it was up to 276 ships. Finally, Colbert encouraged the development of overseas colonies much like those of other European powers. During this time, France established and tightened control over colonies in Canada, French Guiana, and Madagascar.

For all his efforts and financial wizardry, Colbert's successes were limited, largely because he was trying to drag a basically medieval economy into the modern world. Guilds were still powerful and held back progress in new production and financing techniques. Local authorities still jealously guarded their rights to charge tolls on trade. Getting across France involved paying up to 100 such local tolls, which of course stifled trade. The tax burden was extremely unfair, with nobles and the Church virtually exempt from taxation even though they controlled much of the land. Colbert's own techniques of having the government control so many aspects of the economy were heavy handed and tended to stifle initiative. His efforts at trying to centrally control France's overseas colonies were especially disastrous.

However, Colbert did make real progress in developing the French economy. A merchant marine and navy were built. Industries were developed. And for a few years Colbert even managed to run the government at a profit. Unfortunately, Louis' desire for glory and conquests led to a long series of wars that embroiled Europe in a new round of bloodshed and wrecked France's economy. Not even Colbert could do anything to stop that.

The army was another primary object of reform. By the mid 1600's, the old system of recruiting armies and fighting wars was clearly outmoded. Mercenaries were disloyal, untrustworthy, and terribly destructive to friend and foe alike. By contrast, the Swedish army of Gustavus Adolphus and the English army of Oliver Cromwell each had loyal native recruits that proved reliable and effective, while Brandenburg-Prussia was transforming its troublesome nobles into a loyal professional officer corps. These lessons were not lost on Louis and his minister of war, Louvois, who built what amounted to one of the first modern national armies. Three aspects of the army they concentrated on were its training and discipline, its equipment, and its supplies.

First of all, soldiers in Louis' new army, whether mercenaries or peasant draftees, found military life was much stricter and more regularized in several ways. For one thing, instead of mercenary captains who recruited, paid, and commanded them, soldiers now answered to the state and its officers. Along these lines, there was also a regular chain of command from the *Intendant de l'armee* (roughly equivalent to our modern secretary of defense) down through field marshals, generals, colonels, and captains. Officers also got regular training and were much more strictly under the rule of the central government than ever before.

Naturally, the nobles claimed the officers' positions as their birthright. However, the government kept tighter control of its army, largely through new positions filled by men of more humble birth. These *lieutenant colonels* performed many vital duties *in lieu* of the noble officers without actually replacing them. In this way, a more modern army helped Louis bring the old troublesome medieval nobility more tightly under his control.

A second reform was that uniforms and equipment were more standardized, which made the army easier to supply, more efficient, and promoted more of a group identity and higher morale. Finally, the army maintained regular supply lines. This reduced the need for foraging, which increased discipline and control over the army and protected the civilian populace from being plundered.

There were two major factors that limited the effectiveness of Louis' military reforms. For one

thing, Louis's standing army was large and expensive, having some 400,000 men at its height. It is estimated that a pre-industrial society such as seventeenth century France could only afford to support 1% of its population in the military. Louis' army at its height was nearly twice that, which was a terrible strain on French society. This became especially apparent in Louis' later wars when supply lines broke down, which led to foraging and a breakdown in discipline. Second, the expense of Louis' wars forced him to sell military offices, which brought in less capable and dedicated officers. Overall, Louis' military reforms were much like Colbert's economic reforms. They made progress, but met severe obstacles that prevented them from being completely successful.

Despite these limits to Louis' economic and military reforms, France was the most powerful state in Europe by the late 1660's. Louis realized this quite well, in fact probably too well, because he embarked on an ambitious series of policies that nearly ruined France by the end of his reign. There were three areas where Louis chose to show his power: religion, his palace at Versailles, and foreign expansion.

Religion was one aspect of Louis' reign that illustrated the absolute nature of his monarchy quite well. Louis himself was quite a pious Catholic, learning that trait from his mother. However, in the spirit of the day, he saw religion as a department of state subordinate to the will of the king. By the same token, not adhering to the Catholic faith was seen as treason.

As a result, Louis gradually restricted the rights of the French Huguenots and finally, in 1685, revoked the Edict of Nantes, which had given them religious freedom since the end of the French Wars of Religion in 1598. This drove 200,000 Huguenots out of France, depriving it of some of its most skilled labor. Thus Louis let his political and religious biases ruin a large sector of France's economy.

Versailles. Louis' religious faith was largely a superficial one attached to the elaborate ritual of the Catholic mass. This love of ritual also showed itself in how Louis ran his court at his magnificent palace of Versailles, several miles outside of Paris. Much of the reason for building Versailles goes back to

the Fronde that had driven Louis from Paris as a young boy. Ever since then, Louis had distrusted the volatile Paris mob and was determined to move the court away from the influence of that city. Versailles was also the showpiece of Louis' reign, glorifying him as the Sun King with its magnificent halls and gardens.

The palace facade was a quarter of a mile across. The famous Hall of Mirrors alone was 250 feet long. Water pumped from the Seine River to hills 500 feet above Versailles fed its fountains. The Orangery had over 1200 orange trees that were moved inside for the winter. All this was built and maintained at tremendous expense. But it was worth it to Louis, regardless of the burden it put on the French people.

As splendid as it may seem, life at Versailles was not always such a picnic. The site itself was on low marshy ground that made it unhealthy to live in. Except for a few magnificent rooms and bedrooms, most people had small cramped rooms with little or no ventilation. Nevertheless, a noble was considered socially and politically dead if he did not live at Versailles. He lived there at his own expense and was expected to keep up a sumptuous life style in order to be a proper ornament for Louis' court. The seemingly endless round of masquerades, plays, operas, and parties eventually grew old to even the most ardent partygoers. For many, life became a bitter series of petty intrigues over such things as who could stand closest to Louis when he held court or got dressed in the morning. Some even saw this as a plot to ruin the nobles by making them go bankrupt while they were trapped in the gilded cage of Versailles. And indeed, Versailles did bankrupt many nobles along with the French government, helping lead to the French Revolution some 75 years after Louis died.

Louis' diplomacy and wars. Just as Louis's palace at Versailles dominated European culture during the late 1600's and early 1700's, his diplomacy and wars dominated Europeans political history. As Louis himself put it: "The character of a conqueror is regarded as the noblest and highest of titles." Interestingly enough, he never led his troops in battle except for overseeing a few sieges from a safe distance.

Louis' main goals were to expand France to its "natural borders": the Rhine, the Alps, and the Pyrenees. This, of course, would make him enemies among the Dutch, Germans, Austrians, Spanish, and English. Therefore, Louis' diplomacy had to clear the way to make sure he did not fight everyone at once. For this purpose he skillfully used money to neutralize potential enemies (such as Charles II of England in the Secret Treaty of Dover) and extracted favorable terms from stalemate or losing situations. But Louis could also make some fateful blunders to hurt his cause. His obsessive hatred of the Dutch dominated his policy too much, as did his own self-confidence and arrogance in trying to publicly humiliate his enemies. However, this just alarmed Louis' enemies more, especially the Dutch, Austrians, and English, who allied against Louis to preserve the balance of power.

Several new inventions transformed the warfare of this period. First of all there was the bayonet, invented in Bayonne, France around 1670. This blade, when attached to the end of a musket, transformed it into a short pike, thus eliminating the need for separate pikemen to protect the musketeers in hand-to-hand combat. Second, there was the flintlock musket, which provided more reliable firing and faster loading than the old matchlock muskets. Finally, there was the introduction of paper cartridges with pre-measured amounts of gunpowder that also sped up the process of loading in combat. With all infantrymen carrying flintlock muskets, premeasured charges of powder, and bayonets for hand-to-hand combat, generals could create much less dense formations and greatly stretch their battle lines.

These new linear tactics vastly increased European armies' firepower and warfare's destructiveness. They also made armies harder to control since they were stretched out over such a great distance. As a result, discipline was tightened even more, which further increased the power of the state over its armies. It also made it harder to attract recruits, leading to a growing reliance on peasant draftees.

The general trend in Louis' wars was for them to become increasingly longer, bloodier, and less successful. His first major conflict, the War of Devolution, lasted only two years (1667-1668). Louis' goal was to conquer the Spanish Netherlands (modern Belgium), which would give him control

of the mouth of the Rhine and much of Germany's trade.

At this point, Colbert's financial measures provided Louis a strong economic base with which to wage war. Louis' military reforms had also given him the best fighting machine in Europe. The system of supply lines worked so well that the French officers were even supplied with silverware for their tables. As a result, Louis gained several strategic towns and fortresses in the Spanish Netherlands. However, Europe's suspicion and fear of French aggression had been aroused, and each succeeding war would be progressively harder for Louis to win.

The Dutch War (1672-78) brought in the Dutch Republic, Spain, Brandenburg-Prussia, Denmark, and Austria against Louis. French progress was much slower, and fighting much costlier, as the Dutch in particular fought desperately to defend their homeland, even opening the dikes to flood out the French. Although Louis gained nothing against the Dutch, he did win lands along the Rhine at the expense of various German states, but at considerable cost. France lost its two best field marshals, and the French people endured ever-higher taxes, some peasants even being reduced to making bread from acorns and roots.

Louis' next adventure, the War of the League of Augsburg, also known as the Nine Years War (1688-97), embroiled Europe in an even more prolonged and fruitless conflict. French expansion was directed across the Rhine into Germany while Austria was preoccupied with its Turkish war. Austria put the Turks on hold and allied with the Dutch, English, and several German states to stop French aggression. Fighting raged through most of the 1690's. Peasants were drafted in greater numbers, taxes were raised to intolerable heights, and a major famine in 1694 merely added to the misery. Finally, peace was made in 1697 with little changed, except for everyone being severely weakened by the senseless struggle. By 1700, France's population had declined from an estimated 23,000,000 in 1670 to 19,000,000.

Unfortunately, a new and bloodier war soon arose. This time the prize was Spain and its extensive empire, left without a ruler by the death of Charles II. Louis' grandson had an excellent claim through Louis' wife, a Spanish princess. Predictably, the

rest of Europe would not tolerate a French Empire that surpassing even that of Charles V in the 1500's. The resulting conflict, the War of the Spanish Succession, would bring twelve more dreary years of warfare and destruction to Europe (1701-13).

For the first time, Louis' generals suffered decisive defeats, mostly at the hands of the brilliant British general, John Churchill, the Duke of Marlborough. French armies were thrown on the defensive, and French peasants were drafted in growing numbers to defend their homeland. Resistance stiffened and the war ground down to a bloody stalemate. Exhaustion on both sides finally led to the Treaty of Utrecht in 1713. Louis' grandson took the throne of Spain and its American empire, but the French and Spanish thrones could not be united under one ruler. Austria got the Spanish Netherlands to contain French aggression to the north. Just as the Treaty of Westphalia in 1648 had contained Hapsburg aggression, the Treaty of Utrecht contained French expansion. Two years later Louis XIV was dead, with little to show for his vaunted ambitions as a conqueror except an exhausted economy and dissatisfied populace.

Results of Louis' reign. The age of Louis XIV was important to European history for several reasons. First of all, it saw the triumph of absolutism in France and continental Europe. Versailles was a glittering symbol and example for other European rulers to follow. Any number of German and East European monarchs modeled their states and courts after Louis XIV, sometimes to the point of financial ruin. Second, Louis' wars showed the system of Balance of Power politics working better than ever. French aggression was contained and the status quo was maintained. All this had its price, since the larger sizes of the armies and the final replacement of the pike with the musket took European warfare to a new level of destruction. Finally, Louis' reign definitely established France as the dominant power in Europe. However, the cost was immense and left his successors a huge debt. Ironically, the problems caused by Louis XIV's reign would help lead to the French Revolution in 1789 and the spread of democratic principles across Europe and eventually the world.

Dawn of the Sun King: Louis' Early Life

Louis, known as the Sun King since he was born on Sunday, was supposedly born with two teeth, making him very unpopular with wet nurses. He was called the “God Given” because his parents had been childless for twenty years. Even more surprising, a baby brother arrived a couple years later. Louis came to the throne at the age of 4 years. Supposedly, as he was brought to his dying father’s side, the king asked who was there and his son said “Louis XIV”.

***The Fronde (1648-53)* was a popular revolt caused by several factors: the heavy tax burden during the Thirty Years War, the nobles’ anger at the crown’s steady reduction of their power, and the efforts of the high court (*parlement*) to limit the crown’s growing authority. Triggering it was a government attempt to get the chief judicial magistrates to give up four years’ salary to help pay for the Thirty Years War. When the Paris *parlement* (high court) countered with a petition to limit royal power, Cardinal Mazarin and Queen Anne had the leaders arrested. This sparked an uprising by the Parisians, forcing Anne and Mazarin to give in for the time being (August 1648).**

However, when the Thirty Years War ended in October, Anne, Mazarin and Louis left Paris to join the royal army, now freed to take action against the Fronde. They blockaded Paris until a compromise peace was arranged in March 1649.

A second Fronde, led by the princes and nobles, broke out in 1651 after Mazarin arrested the Prince de Conde, who had helped suppress the first uprising. At one point, the royal family had to flee Paris. However, the victorious nobles had a falling out among themselves, opening the way for the royalist party to defeat them. This was

the last open challenge by the nobles to royal authority. The Prince de Conde was forgiven by Louis and went on to become one of France's most celebrated generals.

The battle of Faubourg in 1652 where the Prince de Conde's army was saved from defeat against royalist forces by timely cannon fire from the Bastille.

Peek-a-boo doesn't work with kings. An early event that had a huge effect on the young Louis took place during the Fronde. The Paris mob, actually concerned for the young king's safety, stormed into the palace to make sure Mazarin hadn't taken him away. Louis' mother met the mob and told them the king was asleep, so they tiptoed into his room to check on him. In fact, Louis wasn't asleep, but he was terrified by the event. He never forgot that night nor forgave or trusted the Parisians. Supposedly, this is what influenced him to move the court outside of Paris to Versailles.

Mazarin (above) never assumed priestly vows and was awarded the title of cardinal for military service he had rendered the pope. He may have been secretly married to Louis' mother, Anne of Austria, after Louis XIII died.

Early on, Louis learned to put aside personal feelings in favor of his duty as a king. Although he had fallen in love with Mazarin's niece, Maria Manzini, he agreed to marry a Spanish princess,

Maria Theresa, whom he had never met in order to seal a treaty with Spain.

One way to understand Louis' reign is to view it as a highly ritualized and scripted play, where each character, including the king, had his strictly assigned role. While this heavily restricted Louis' own daily life, it also restricted the movements of everyone at court, keeping them perfectly in line if they wanted to enjoy the king's favor.

That being said, Louis was a dashing young man well known for his romantic exploits, including climbing the rooftops of Paris to gain entrance to various fair maidens' bedrooms.

Louis may have been as short as 5'3", but he augmented his height with high heels and big hair (wig). Height was considered an important aspect of royal bearing. Artists typically portrayed their subjects as taller than they really were.

Louis' Economic Reforms

The draper's son. As one of the newer nobility of the robe, Louis' finance minister, Jean Baptiste Colbert, indulged in nepotism and enriched himself as well, which was seen as just part of the game back then. He apparently was quite vain (or at least insecure about his lineage), and insisted he had Scottish kings as ancestors. He was also quite imperious, ordering nobles about and angering them as much as Mazarin and Richelieu had. He also may have transformed France as much as Richelieu had. As the dying

Mazarin supposedly told Louis: *“Sire, I owe everything to you; but I pay my debt...by giving you Colbert.”*

The French economy at the time was a mess, still trying to recover from the Thirty Years War, the Fronde, and war with Spain, which continued until 1659. As a result, there was a serious depression in the late 1650s.

One thing especially plaguing it were the separate regional economies with their own weights, measures, and worst of all, tolls and tariffs. There were probably 1500 different toll districts in France at the time. Someone crossing from one end of the kingdom to the other would have to pay up to 100 such tolls, which seriously stifled internal trade. Meanwhile most trade outside the country was carried on foreign ships. In addition, guilds still artificially limited production and kept prices high, while poor transport led to starvation in the midst of plenty.

Colbert also faced a huge royal debt of 60,000,000 livres. By comparison, royal revenue in 1661 only equaled half of that, while 9 million livres were spent on interest payments alone.

He started by setting up a Chamber of Justice to investigate any corruption by fiscal agents, tax collectors, and rentiers since 1635. This resulted in sentencing corrupt officials to property confiscations, time in prison or as galley slaves, and in some cases, hanging. This restored 150 million francs to the royal treasury. Colbert then dismissed about half the officials in the Department of Finance along with numerous court officials. He converted old government debts into new ones at lower interest rates, simplified tax collection and cancelled back taxes dating to 1647, knowing he couldn't collect them anyway.

He also lowered taxes in 1661 and mourned having to raise them again in 1667 to pay for Louis' wars and new palace at Versailles. However, he failed to reorganize the tax system was based on the *taille*, in which the burden rested solely on the Third Estate, leaving nobles and Church exempt.

The most notable of Colbert's infrastructure improvements was the Languedoc Canal to connect the Garonne and Rhone Rivers to create a direct link between the Atlantic & Mediterranean without having to sail all the way around Spain & Portugal. It was 162 miles long and reached an altitude of 850 feet above sea level. Barges going up the canal would be towed by horses, oxen, or humans.

Colbert's heavy-handed state control included hundreds of ordinances prescribing methods of production along with the size, color, and quality of products, and the hours and conditions of labor. Boards were established in all towns to inspect work and to deal out public punishments for failing to meet government standards.

Workers were subjected to a quasi-military discipline that punished laziness, cursing, incompetence, drunkenness, disobedience, and irreverence in church, sometimes by flogging. By the same token, wages were low to make French goods competitive outside of France, workdays were long (12 hours or more), while strikes and unions were strictly outlawed. To a large extent, Colbert was just creating medieval guilds on a national level.

Colbert died September 6, 1683 (just as Vienna was about to be saved from the Turks several hundred miles to the east) and was buried at night to avoid insults by an angry mob. His regulations stifled as much as stimulated the economy, being too concerned with control of quality and production rather than more efficient capitalist practices. As one person assessing Colbert's work told him, *"You found the carriage overturned on one side, and you have upset it on the other."*

While Colbert did create several years of balanced budgets, Louis' extravagance and wars would quickly erase any surplus so that by the end of his reign he would be spending his taxes three years in advance.

Louis' Military Reforms

Francois-Michel Le Tellier, the marquis de Louvois (above), took over the army in 1665 at the age of 24. He did his job with energy, clear-sightedness, and brutality, making him one of the most hated men in France. However, thanks to his efforts, the French army was transformed from a quasi-feudal rabble into a modern national army that answered to the state instead of individual generals.

Purging the old army. Much like Colbert did with France's finances, Louvois started with a purge of the old army. However, instead of wasting energy trying to abolish the sale of commissions, he worked to give the king controlling interest in those sales. Louis had already partly accomplished this in 1661 when the Colonel General of the Infantry died and Louis assumed the office himself so that all infantry officers held their offices directly from the king. Along these lines, Louis and Louvois weakened the positions of the Colonel General of the Cavalry and Grand Master of Artillery in their control of commissions in their respective branches of the military.

Next Louvois worked to end the practice of soldier impersonators who would receive soldiers' pay or bounties for enlisting and then desert so they could enlist again. Offenders caught in this scam faced progressively harsher penalties from flogging (1663) to flogging and branding (1665) to execution. Another problem was captains falsifying numbers in their companies so they could collect extra salaries for themselves. Any officers who did this was imprisoned for one month and had to give the soldier who denounced him the hefty sum of 300 livres. A third practice Louvois worked to extinguish was commissioners warning officers of surprise inspections, which allowed corrupt officers to gather temporary recruits or borrow

soldiers from other regiments to fill out their ranks to the numbers they were getting paid for.

The recruits. Louvois worked hard to improve the quality of recruits by tightening state control of the recruiting process while also improving soldiers' opportunities and status. New recruits signed up for 4 years. They must be physically fit, bachelors or widowers, and under 40 years of age.

But as Louis' reign went on, his wars overtaxed France's ability to supply enough qualified recruits, so standards were lowered or ignored, such as the height requirement. There was also widespread kidnapping of recruits for bounties until the authorities were ordered to stop it.

Even as early as 1676 the Duke of Luxembourg described his recruits as "deplorable; a good half of them mere children whom I shall have to send back to France", while by 1689 Louis was being urged to fight a defensive war because of the declining quality of recruits. In 1703 Louis was so desperate for recruits that he offered 5-year exemptions from taxes for anyone who would enlist for three years

Louvois worked to improve a lot of common soldiers, such as ordering lighter punishments than before. Captains still paid their men, but were closely supervised so that men were paid regularly. This led to fewer desertions, although it was still a big problem. Troops got extra pay for serving in plague areas and tax exemptions (ranging from 6 months to life) for valor in combat.

Another issue the state has wrestled with has been long and short-term care of the wounded. Under Louis, field hospitals for the wounded were still privately contracted, being paid per wounded soldier treated. Unfortunately, this system led to many abuses and the state, although still not running its own medical service, kept a closer eye on those who did. Offenders were led through the hospital by a hangman and then banished for life.

Long-term care for disabled veterans was a problem typically ignored by the state, since it saw no major return on its investment, at least in a positive way. Before, such men were often billeted in monasteries, where they would steal food and drink, get drunk and disorderly, and even attack the monks. Finally, the Monasteries struck a deal with Louis, paying him to build and run the first veterans' hospital, the *Invalides*, (below) in Paris (1674).

Louis and Louvois established a modern regular chain of command to replace the chaos & bickering of the old feudal chain of command:

- *Field marshal* who commands an army
- *General* who commands a division
- *Colonel* who commands a regiment
- *Captain* who commands a company

However, while Louis had more control of this hierarchy, nobles still claimed these offices as their birthright. In fact, senior military offices were one type of position commoners could not buy into. Unfortunately, all too often, the nobles who claimed these offices as their birthright also didn't think they had to do many of the jobs now required by these new positions.

Therefore, Louvois injected several new positions beneath the officers who would carry out all the required duties in lieu of the regular officers who either thought they were too good to perform those duties or were at Versailles protecting their positions against court intrigue:

- *Field marshal* who commands an army
- *General* who commands a division
 - *Brigadier general* who does much of the general's job
- *Colonel* who commands a regiment
 - *Lieutenant colonel* who does much of the colonel's job
- *Captain* who commands a company
 - *Lieutenant* who does much of the captain's job

Therefore, the old venal offices of ensign, captain, and colonel could still exist without doing as much harm. These new offices created a poor man's ladder of promotion, allowing men of more humble rank to rise through the ranks by merit.

Training & discipline was another area where Louvois was determined to increase efficiency. For this task he hired Jean Martinet who ruthlessly carried out reforms. In fact, even today, we use the word *martinet*, meaning a harsh disciplinarian. One thing Martinet did was to pressure incompetent officers into selling back their commissions by making their continuance dependent on their units' performance.

Officer training. Martinet realized the officers' poor performance was largely due to discharging them in peace when they would lose their edge. It was probably Louis who suggested putting superfluous officers into a few peacetime regiments until the next war, creating an excellent reserve officer corps, which explains France's ability to rapidly mobilize when war broke out.

Another issue that needed addressing was the old system of attaching young officers to regiments under family friends, hoping to pick up what they could (usually bad habits) until the family lawyer got them their own companies. Such a system provided no regular training for officers. Although they may have picked up some personal skills (e.g., riding horses or sword fighting), they rarely got instruction in how to command soldiers or the more technical aspects of being officers in modern (seventeenth century) armies.

Therefore, in 1682, of a modern system of officer training replaced the old system. There were

nine companies of cadets in frontier towns under the command of governors and instructional staff specifically there to train them. There they were taught drill, the manual of arms, musketry, dance and other social graces (for formal social occasions where they needed to represent their king as cultured men), riding, fencing, geography (especially how to read a map), and math for tasks involving logistics. A year later, Louis remarked that not even his musketeers put on a better parade than Besancon Company of officer trainees.

Infantry training. When the French commander of the expedition sent to help the Hapsburgs against the Turks in 1664 reported that many so-called trained soldiers had never fired musket and didn't know its theory, Louvois determined to institute regular training in musketry and the drill and march.

However, Louvois remained conservative about weaponry, keeping the firelock musket over newer more efficient flintlock fusil, even though reports showed all the French firepower at the Battle of Steenkirke came from the few fusils they had picked up from routed infantry. Even as late as 1703, one-third of the French infantry were still armed with pikes, despite the invention of the bayonet (c.1670), which eliminated the need for pikes, thus allowing each soldier to have a musket and increasing the army's firepower immensely.

Cavalry was still considered the arm to win battles, with infantry used mainly for softening up the enemy line to set it up for a cavalry charge. Since officers were nobles who normally rode horses, they understood cavalry training better than they did infantry training. There were some weapons changes, mainly curved sabers replacing swords and two carbineers (carrying short muskets) being added to each cavalry squad in 1679.

Although Louvois tightened discipline in the French army, he operated under the naive assumption that he could tell his men to rape and plunder in enemy territory (which was done as a matter of policy in some cases) and then expect

them to return to normal discipline. Unfortunately this contributed to a rapid decline of discipline in the later part of Louis' reign.

Uniforms, which first evolved on a regimental level, not only helped soldiers distinguish friend from foe on the increasingly smoky battlefield, but also gave them a stronger group identity leading to higher morale and reliability in battle. Until uniforms were imposed throughout the army in 1682, one might find regiments on both sides of the field wearing the same or similar colors. Even in the early stages of the American Civil War in the 1860s, there were Union regiments in grey uniforms and Confederate regiments in blue, not to mention a regiment on each side wearing uniforms modeled after French Zouaves.

Regular supply lines were a radical innovation for the seventeenth century, not having been used since the time of the Romans. Louis' supply magazines revolutionized warfare since cavalry could campaign any time of year, and not have to wait for spring forage.

Infantry on the march were issued six days' worth of hard biscuits with holes in the center they could string on bandoliers. It may have been Louis' idea to create portable ovens that could move with or just behind the army and bake six days' rations in one day. Unfortunately, officers never checked their men's rate of consumption or stopped them from trading biscuits to the locals for wine. Therefore, despite the army's best efforts, the soldiers often went into battle hungry, and sometimes drunk.

Higher officers were often no better in rationing food. For example, General Boufflers who was defending Lille (1708) kept issuing the same amount of rations for his garrison during the siege despite mounting casualties and a declining number of men to feed. As a result, he ran out of food and surrendered.

Other problems included troops looting the store houses and dishonest contractors who would only half bake bread so it weighed more and they were paid more.

In fact the private contract system still hampered every aspect of the army, since the state still didn't have the means to do everything itself. Therefore, until 1672, the artillery was a civilian enterprise where contractors hired soldiers to move their batteries and were paid for every gun they brought into action. This was still better than the Spanish system where contractors were paid each time they moved a cannon, leading to them constantly moving their cannons but never firing them.

Supply and transport were also on a contractual basis. The French lost the Battle of Consaarbruck in 1705 because the artillery contractor had loaned out his horses to the cavalry, so he was unable to bring a single gun into action. The cavalry very likely had no horses because they were let out for hire to local farmers.

In some cases, when fodder for their cavalry horses cavalry failed to arrive, troopers had to stop to cut their own fodder (below). Such breakdowns in supplying the army inevitably hurt its combat effectiveness.

In one case, Charles IV of Lorraine, needing cavalry horses, summoned a meeting of all the local bishops and rich clergy. While he was inside giving a stirring speech about France's

peril, his troopers were outside stealing the clergy's horses.

Another important element of France's defenses was a ring of 90 fortresses around France designed by the foremost fortifications engineer of the day, the Marquis de Vauban. His fortresses were designed using the latest state of the art math. In addition to defending France, they also served as advance supply bases for invading other countries.

A model of Vauban's fortifications at Neuf-Brisach (left) and how they are still preserved today.

Because of the strength and importance of fortified centers, warfare in the age of Louis XIV typically got bogged down in long sieges, thus prolonging the wars and putting severe strains on the ability of Louis' system to keep supplying its troops.

There were two major factors that limited the effectiveness of Louis' military reforms. For one thing, Louis's standing army was large and expensive, having some 400,000 men at its height. A pre-industrial society such as seventeenth century France probably could only afford to support much more than 1% of its population in the military. Louis' army at its height was nearly twice that, which was a terrible strain on French society. This became especially apparent in Louis' later wars when supply lines broke down, which led to foraging and a breakdown in discipline. Second, the expense of Louis' wars forced him to sell military offices, which brought in less capable and dedicated officers. Overall, Louis' military reforms were much like Colbert's economic reforms. They made progress, but met severe obstacles that prevented them from being completely successful.

Micromanagement by the king was another serious problem. Largely because of his bad

experience with rebellious generals as a boy, he had a near obsession with reducing his generals to impotence, or at least making them constantly aware of his guiding hand. Louis took flattery seriously, which made him fancy himself a great commander who could as easily direct and win battles from Versailles as from the field, which led to ever stricter control from Versailles. In the War of the Spanish Succession, French generals couldn't move without the king's permission, so that by the time a request was sent to Versailles and permission was brought back to the front, the situation had changed.

The End of Religious Freedom in France

"I king, I law, I faith" is how Bishop Bossuet summed up what he thought the king's position on the Huguenots should be. At first, Louis' relations with the Huguenots had been good. They had supported him during the Fronde, and he had reciprocated with a public thanks. However, as Louis' reign progressed and his ego grew, he found himself under growing pressure from his bishops to bring the Huguenots in line with the rest of Catholic France.

Louis proceeded slowly at first and then gradually turned up the pressure. In 1661, he outlawed Protestantism in Gex, an almost totally Protestant area that had come under French rule since 1598. Therefore, in his mind, this region did not come under the protection of the Edict of Nantes. However, for those paying close attention, Louis was showing his hand.

Over the next twenty-five years, the king progressively tightened the screws on the Huguenots with series of new restrictions:

1664- Louis made advancing to guild master harder for Protestants.

1666- Huguenots were forbidden to establish new academies.

1669- Huguenots caught trying to emigrate had their property confiscated, and anyone helping them was sent to the galleys for life.

1677- Louis changed his tactics and offered cash inducements for converting.

1679- Relapsed converts lost their property and were banished.

1681- Louis instituted the *Dragonnades*,

quartering his troops only with Huguenots.

Quartering troops on private citizens was always unpopular, creating an unfair burden on families who may or may not be compensated. Even worse, it put civilians at the mercy of soldiers who typically came from disreputable, if not criminal backgrounds. Normally, they were under strict orders to respect the families they were living with, but billeting, such as in this case, could be a form of punishment to pressure people into falling into line with the government. The soldiers involved understood this perfectly and often exploited it ruthlessly, using supposed apostolic zeal as an excuse to rob, beat, and rape members of their host families.

Huguenots fleeing religious persecution

The *Dragonnades* had their effect, leading to thousands of Huguenots converting and thousands more emigrating from France. As a result, Louis believed few Huguenots were left in France and he could move against the rest with impunity. From 1682 to 1685, out of 815 Huguenot churches, 570 were closed, many of them torn down.

In fact, for whatever reasons, between 1600 and 1685, when Louis finally revoked the Edict of Nantes with the Edict of Fontainebleau, thus ending religious freedom for Protestants, the number of Huguenots in France had already fallen by two-thirds, from 1.5 million down to 500,000. And of that remaining half-million, nearly 200,000 (40%) would leave France for other more tolerant countries.

A New Home for the Sun King

Louis' religious faith was largely a superficial one attached to the elaborate ritual of the Catholic mass. This love of ritual also showed itself in how Louis ran his court at his magnificent palace of Versailles, several miles outside of Paris. Much of the reason for building Versailles goes back to the Fronde that had driven Louis from Paris as a young boy. Ever since then, Louis had distrusted the volatile Paris mob and was determined to move the court away from the influence of that city. Versailles was also the showpiece of Louis' reign, glorifying him as the Sun King with its magnificent halls and gardens.

Besides a dislike of Paris, Louis also built Versailles from a love of outdoors and/or a desire to show his power by building an unfortified palace in the open country. Until the court officially moved to Versailles in 1682, Louis used Versailles as an escape from the crowded activity of his palace in Paris.

During the *ancien regime*, a hat and sword could be hired at the front gate in order to be properly attired to visit the Grand Apartment. Monks were not allowed in.

The palace facade was a quarter of a mile across. The famous Hall of Mirrors alone was 250 feet long. Water pumped from the Seine River to hills 500 feet above Versailles fed its fountains. Of course, all this was built and maintained at tremendous expense. But it was worth it to Louis, regardless of the burden it put on the French people.

Symbolism in numbers. The palace wings had 153 windows, that being the theosophical sum of 17 (i.e., the sum of all the integers from 1 to 17). Seventeen symbolized the path to spirituality, as in the number of rows of columns in the Parthenon and windows in the Hall of mirrors. The garden facade of the central part of the chateau is architecturally deceptive, because there are no rooms behind the windows on the top floor.

The central walkway in the South Garden is lined with 16 yew trees, the number symbolizing

material power. Each garden bed has 6 yew trees, the number for Satan and dispersal. The yew tree also symbolizes death. All of these serve as an allegorical warning against the dangers of materialism.

To celebrate the scientific revolution then taking place, Versailles was even aligned 23.5° off of true north to correspond to the tilt of the earth's axis.

The Orangery in Louis' time had 2000 Orange trees (1800 presently) that were moved indoors for the winter. Since they were pruned closely for more geometrical shapes in the manner of French gardens, they bore no fruit.

Neptune's fountain, with 22 jets and 99 vases, lies at the north end of the North-South axis of the palace grounds. As Louis, his artists, and most of his courtiers knew, north was the direction where life began.

The Fountain of Latona (above) in the center of the grounds, showing the mother of Diana and Apollo pleading to Zeus to punish the villagers trying to deprive her and her children of water. It also shows the evil villagers being turned into frogs. Just as Apollo, the Sun god represents Louis, the Sun King, Latona represents Louis' mother, Anne of Austria. Her triumph may also represent the triumph in the Fronde over the vulgar populace (i.e., frogs), as does another statue of Apollo killing the Python at Delphi.

This fountain looks toward the far end of the Versailles lawn and the Apollo Basin, a statue of the Sun God emerging to cross the heavens.

In addition to the references to Louis, Apollo also had several parallels with Christ: being born after a journey imposed on his mother, receiving lavish gifts shortly after being born, a forced exile caused by the wrath of the mighty, devotion to his mother, and defeat of the serpent.

The extensive hydraulic systems for bringing water to Versailles' fountains used 10 windmills and 120 horses working in relays of 40 around the clock. There were 200 kilometers (130 miles) of subterranean channels and aqueducts built to supply the fountains of Versailles. To conserve water, fountain guards were ordered to whistle when Louis XIV approached, so that the fountains could be turned on.

The various statues around the pool represent the great rivers of France. They are reclining so they don't interrupt the majestic view of Louis' palace. The grounds are also lined with numerous classically inspired statues.

However, most of the chateau's grounds retained their natural simplicity so Louis could enjoy his hunts, among other things.

Inside the Palace, the most striking room is The Hall of Mirrors, which has 17 windows (the number symbolizing the quest for spirituality) opposite 17 mirrors. In front of each of the windows was a solid silver tub with an orange tree and between them were 16 solid silver tables. There were also 17 great silver chandeliers, 26 smaller ones and countless candelabra on gilded stands.

The Palace was so poorly policed that thieves stole gold bullion from curtain fringes of a salon and the king's silver chamber pot from under his

bed. Supposedly nobles were allowed to hunt foxes in the palace during winter.

The overall theme for the ceiling paintings in the Hall of Mirrors was a history of Louis' reign. (Colbert advised the king not to glorify himself in a way that would insult other countries.) The central ceiling painting was originally titled "*Louis the Great in the flowering of his youth, took the helm of the State, and forgoing repose and pleasure, gave himself over entirely to the love of true glory.*" Luckily, Louis chose the simpler title *The King Rules Alone*, so we wouldn't have to waste our time reading the longer one.

As splendid as it may seem, life at Versailles was not always such a picnic. The site itself was on low marshy ground that made it unhealthy to live in. Except for a few magnificent rooms and bedrooms, most people had small cramped rooms with little or no ventilation. Nevertheless, a noble was considered socially and politically dead if he did not live at Versailles. He lived there at his own expense and was expected to keep up a sumptuous life style in order to be a proper ornament for Louis' court. The seemingly endless round of masquerades, plays, operas, and parties eventually grew old to even the most ardent partygoers.

For many, life became a bitter series of petty intrigues over such things as who could stand closest to Louis when he held court or got dressed in the morning. Some even saw this as a plot to ruin the nobles by making them go bankrupt while they were trapped in the gilded cage of Versailles. And indeed, Versailles did bankrupt many nobles along with the French government, helping lead to the French Revolution some 75 years after Louis died.

There were countless squabbles at Versailles over who outranked whom, who walked closest to the king, helped him dress or undress, who had to pass the collection plate in mass, which churchyard one was entitled to be buried in, and who got to hold Louis' potty chair Other examples abounded:

- A woman visiting another of superior rank at her toilette was only entitled to have one door of

the double doors opened for her.

- A man receiving the servant of a superior still had to remove his hat as if that superior were present.
- Even a simple meeting between two nobles was preceded by a meeting of their servants to decide who got to sit in a chair with arms, a chair without arms, a stool, or have to stand.

Once, a planned meeting between Louis and visiting Austrian royalty never took place because they couldn't agree on whether or not the Austrian got a chair with arms.

Good manners were also of extreme importance. The polite way to knock on someone's door at the palace was to scratch it with the nail of the pinky finger.

Living conditions. Most apartments were small and poorly ventilated, some of them overlooking the latrines. Smoke backed up into them since raising chimneys would mar the visual effect. Shutters to keep out the cold weren't allowed for the same reason.

Given the lack of adequate or convenient bathroom facilities, stairways often doubled as latrines for the nobles. The palace was so vast that one woman who fell and broke her leg wasn't found for several days.

Living at Versailles was very expensive. A "modest" noble should maintain at least 11 servants & 2 coaches to keep up appearances.

A less modest noble would have up to 75 servants & 40 horses.

The king's bedroom. The balustrade in front of his bed separating the king from the populace serves the same purpose as an altar rail separating god from the congregation. Even when empty, passersby had to kneel as if the king were present.

His bed was crowned with plumes of ostrich feathers, signifying his unearthly majesty. However, just as all ostrich feathers are equal in

length, so are all believers spiritually equal, a slight concession to the public's feelings.

The Queen's bedroom was designed with a parallel, but much less exalted, form and function to the king's bedroom. Her attendants would have to sit on stools, because their dresses were too bulky to fit in chairs. Louis would dutifully "visit" the queen's bed twice a month. Supposedly you could always tell, because the next day she had a certain glow about her.

The king's mistresses. Madame La Valliere (above), the first of Louis' three official mistresses, dressed as the goddess of the hunt, Diana. She was once described as having "a lovely complexion, blonde hair...no ambition, no points of view".

After being replaced as Louis' favorite by one of her handmaids, Madame de Montespan, she still hung on at court for several years as one of Montespan's hairdressers! Apparently she never caught on that Madame de Montespan had used her position to introduce herself to Louis and replace Madame La Valliere as the king's mistress.

She quietly retired at the age of 30 to a convent, as did Louis' other mistresses and many girlfriends after falling from his favor. This sparked the comment that the king's embrace saved many women's souls.

Louis' second official mistress was the Marquise de Montespan, or as her husband caustically referred to her, the "late Madame de Montespan." She kept the court witty and lively before herself retiring to a convent. In one painting she posed with the children she bore

Louis, the position of her hand on her breast indicating she was pregnant again.

Madame de Maintenon became Louis' wife after the death of Marie-Therese of Spain in 1683. Partly due to her influence and partly due to his old age and poor health, Louis ran a much more sober court in his later years.

Since society orbited around him much as the planets orbited the sun, Louis had various apartments leading to his bedroom named for various deities along with the planets they represented: Mars, Venus, etc.

A Day in the Life of the Sun King

The second floor antechamber (above) outside Louis' bedroom was where courtiers would gather each day by 7:45AM to greet the king as he rose for the day. It was important to be there on time, which made it particularly difficult for those who could not secure an apartment in the palace and had to travel in each morning from town.

The king's day began as the royal watchmaker came in to wind the royal clock and the Royal wigmaker entered with a glass-fronted wardrobe carrying all the royal wigs, each on its own pedestal. Two wigs would be chosen: a short dressing wig and a more formal wig of the day.

8:00AM: The first *valet de chambre* woke, or pretended to wake, the king. The news of the king awakening rustled excitedly through the crowd in the anteroom.

8:15: The First Physician, First Surgeon, and the king's old nurse would enter to enquire of his health, rub him down and change his bed-shirt.

At this point, courtiers with the coveted right of *grandes entrees* now entered. This was the best time to ask the king a favor.

The Grand Entree left while the king recited the Office of the Holy Ghost.

The Grand Entree then reentered to watch Louis put on a dressing gown and wig.

Then the common nobles crowded in to watch the king dress, one of them remarking that he put on his breeches "very cleverly and gracefully".

Attending to Louis by holding the royal potty (*chaise percée*, meaning pierced chair, above) was a much-coveted honor among nobles. This was also a prime time to petition him for a favor since he was already in a "giving" mood. Along with many of the decorations in the palace, the original *chaise percée* was also stolen.

10-10:30 AM: Louis attended mass, which he supposedly missed only once during his reign. Therefore, it was a good idea for courtiers also to attend, although they socialized and laughed shamelessly during mass.

After that, Louis held council or (on Thursdays) private audiences where he could loosen up a bit while being away from the public. He then had Dutch newspapers read to him, even though he referred to the Dutch as "maggots". This might also be the time for other public functions (like present-day photo-ops) such as receiving courtiers with their requests....

... or the official founding of the Order of the Knights of St. Louis (1693)...

... or the official founding of the Academy of Sciences in accordance with his role as primary patron of arts and sciences in the newly emerging Age of Reason (even though he could barely read)...

... or receiving foreign ambassadors, which was also a good opportunity for him to show off his wardrobe, such as the diamond-encrusted robe worth \$25,000,000 he wore to receive the ambassador of Siam.

2PM- Back to the king's bedroom where he had lunch by himself or with a select few while gazing out his window. According to Louis' second wife, Madame de Maintenon, "*I have often seen him eat four plates of soup, a whole pheasant, a partridge, a plate of salad, mutton au*

jus or a l'ail, two big slices of ham, a whole plateful of pastry, and besides these, fruit and hard-boiled eggs.” In addition, he devoured oysters by the dozen, while between meals he gorged himself on pastries, preserved fruits, cider and lemonade.

Each morning Louis would announce if his afternoon activity would be a hunt or promenade (either strolling or boating).

Louis was such a brisk walker that few beside Madame de Maintenon (the queen), and Madame de Chevreuse could keep up with him. So, if you couldn't keep up, it was advisable you stayed home.

On the hunt, Louis was reputed to be an excellent shot. Sometimes thousands of game birds would be released for his hunting pleasure. Running after him would be a servant who carried wine and glasses in case the king was thirsty. He rarely was, thus not lightening the servant's load.

In old age, Louis would ride to the hunt in a carriage.

Louis and the nobles kept up to 500 hunting hounds at Versailles. Apparently, they weren't very nice, because one pack was known as the "No Quarter Pack."

Three nights a week, Louis provided all sorts of entertainment: tournaments, hunts, tennis, billiards, bathing and boating parties, dinners, dances, balls, masquerades, operas, concerts, plays, and ballets. Louis himself once performed in a ballet.

The Opera House, built by Louis XV in 1770, had a stage that could be lowered by mechanical means, thus creating a perfectly oval ballroom. To that effect, the backstage area was decorated just like the rest of the theater.

Three other nights a week the king held evening entertainment in the royal apartments. These included dancing, cards, and billiards. Louis kept careful track of who attended each of these events. Being absent, especially in Paris where only disreputable types went, could destroy a noble's career.

Gaming nights were one occasion where court etiquette was loosened a bit. Nobles could shout, curse, spit, and bang their fists on tables as they watched their fortunes go up in smoke. The one thing they could never do was discuss politics. That was the king's sole prerogative. Likewise, women's conversation topics were limited to innocuous subjects such as fashion and court gossip.

The endless round of balls, masquerades, concerts, and gaming nights proved to be tedious to most courtiers. Gambling was one exciting activity that was allowed. Many nobles gambled with reckless abandon, oftentimes to ruinous results.

10PM- Louis went to the Porcelain dining Room for dinner, which he might eat in public. Hordes of spectators would flock from Paris to view this spectacle, at times passing peasants dead or dying from starvation, as during the famine of 1705-8.

(screen shot of a royal supper from the movie *Marie Antoinette*)

Without a kitchen in the palace, meals were prepared in the village and carried past hungry peasants who bowed and marveled that one man

could eat so much. As a result, Louis rarely got a hot meal, even though the kitchen staff numbered 498 people.

Nobles competed for the honor of serving as royal tasters, largely because they got the leftovers. What was left from that was sold in town. That was a lot, since a typical dinner consisted of 8 courses with 8 dishes each. From those 64 dishes, Louis would generally eat only from about 20.

At this point in time, adults ate with their fingers, only children being allowed to use eating utensils.

At Marley, where things were more relaxed, Louis had a habit of rolling bread into little pellets and tossing them at the ladies. Reciprocal behavior apparently wasn't expected as one woman found out when she retaliated by dumping her salad on Louis.

After dinner, the royal potty again. Louis's ritual for going to bed was largely the same as in the morning, only in reverse (the ritual that is, not his bodily functions). After saying goodnight to the ladies and giving the night's password to the captain of the guard, Louis would retire for the night, often taking a bedtime "snack" of three loaves of bread, two bottles of wine, and three cold dishes.

The Chateau de Marley. When the court officially moved to Versailles in 1682, Louis used another, more rustic chateau, Marley (below), as a refuge to which he and specially invited guests could retreat. To be invited here with the king was one of the highest honors.

It could also be a burden since the king would ride with both the queen and his current mistress in the same carriage, even when the mistress was pregnant with his child. In addition, he would constantly offer them food and drink while taking none himself. Since it was impolite to refuse Louis' offers of refreshments and he didn't like to make

"potty stops", one gets the image of a potentially agonizing ride for the ladies.

Versailles by the Numbers

- 800 hectares (2,000 acres) of grounds
- 20 kilometres (12 miles) of roads
- 46 kilometres (27 miles) of trellises
- 200,000 trees
- 210,000 flowers planted every year
- 132 km (80 miles) of rows of trees
- 20 km (12 miles) of enclosing walls
- 50 fountains
- 620 fountain nozzles
- 35 km (21 miles) of water conduits
- 11 hectares (26 acres) of roof
- 51,210 square meters of floors
- 2,153 windows
- 700 rooms
- 67 staircases
- 6,000 paintings
- 1,500 drawings & 15,000 engravings
- 2,100 sculptures
- 5,000 items of furniture & objects d'art
- 3,600 cu. meters of water consumed per hr. during full Play of Fountains
- 23 hectares (55 acres): surface area of the Grand Canal
- 5.57 kilometres (3.3 miles): perimeter of the Grand Canal
- 150 varieties of apple and peach trees in the vegetable Gardens

Louis' Diplomacy and Wars

Louis' avowed goal in foreign policy was to take France to its "natural" borders. The Atlantic to the west and the Pyrenees and Alps to the south and southeast were pretty distinctly defined. However, the Rhine to the east and northeast was another matter, at least to Louis, and that was where there was a lot of potential trouble.

In some ways, Louis' diplomacy could be clever and devious, especially in the use of bribes. For

example, Charles II of England (1661-85) had spent much of his early life in exile in France after the Puritan victory in the English Civil War (1642-5). He was secretly Catholic, pretending to be Protestant in order to keep his throne when he was restored to it in 1661. Much of his ability to survive came from the Secret Treaty of Dover whereby Louis secretly funded Charles so he wouldn't have to make concessions to a Puritan Parliament to get money. In return he allied with Louis against the Dutch in the Dutch War and even promised to turn England Catholic if the opportunity presented itself. Unfortunately for Louis, it never did.

However, Louis' ego and obsessive hatred of the Dutch "maggots" seriously hurt him. Paintings gloating about victories over other states, like the one above depicting a defeated Holland, made him few friends and eventually drove Britain, the Dutch Republic, Austria, and various German states to band together to stop him and maintain the balance of power in Europe.

Another Military Revolution. New weapons and new tactics for using them were emerging in the late 1600s. One such weapon was the flintlock musket. When the trigger was pulled, the hammer and clamp holding the flint (1) hit a piece of steel (2). This created a spark that ignited the priming powder in the priming pan, which then ignited the main charge of powder in the barrel through the touch-hole (3). The flintlock was more reliable and efficient than the matchlock as well as being simpler and cheaper to make than the wheel lock. Thus states could afford to equip whole armies with flintlock muskets.

The second innovation was mass-produced paper cartridges, each holding one pre-measured charge of gunpowder and a musket ball. The soldier would rip off one end with his teeth and pour the powder & then the musket ball into the barrel. This saved time by not having to use the

more cumbersome "twelve apostles" or measure an individual charge for each shot.

Finally, there was the bayonet, supposedly invented in Bayonne, France (c.1670), which made the musket into what amounted to a short pike. This eliminated the need for pike men, thus making it possible to arm everyone with muskets and dramatically increase an army's firepower.

In order to maximize an army's firepower, generals replaced the thick blocks of infantry with extended lines stretching a mile or more. These new *linear tactics* vastly increased European armies' firepower and warfare's destructiveness. They also made armies harder to control since they were stretched out over such a great distance. As a result, discipline was tightened even more, which further increased the power of the state over its armies. Tighter discipline and bloodier battles also made it harder to attract recruits, leading to a growing reliance on peasant draftees during the 1700s.

The War of Devolution (1667-8). When Louis married the Spanish princess, Maria Theresa, she was in line to inherit the Spanish Netherlands when the Spanish king, Charles II died. Spain had agreed instead to pay 500,000 gold crowns to Louis in return for keeping these provinces. However, since Spain never paid the money, Louis claimed the Spanish Netherlands *devolved* to him.

At the time, other states were largely preoccupied with other matters, The Dutch and English were involved in the Second Anglo-Dutch naval war. Meanwhile, Leopold I of Austria, still tied down with the Turks in the East, was neutralized by a promise from Louis of a share in the spoils.

On May 24, 1667 55,000 French troops crossed into the Spanish Netherlands against only 8000 Spanish troops and overran most of it. French supply lines worked so well its officers were even provided with silverware. Flanders fell so

quickly that Louis invaded Franche Comte. However, its rapid fall triggered a triple alliance of Sweden, England, and the Dutch to stop Louis.

Louis saw he had moved too quickly and agreed to the Treaty of Aix-la-Chapelle (1668). While he kept strategic forts and towns in Flanders, he gave back Franche Comte making a deal with Austria to get it when the king of Spain died, which was expected any day.

Louis' wars were largely taken up with sieges that were carried out with giant siege guns while soldiers edged their trenches closer to the fortifications for undermining.

The Dutch War (1672-78). In 1672, Louis resumed his march to the Rhine, this time against the Dutch. In accordance with the Secret Treaty of Dover, Charles II of England joined him in what is known as the Third Anglo-Dutch War. As a result, the Dutch found themselves assaulted on two fronts. On the land front, 130,000 French troops marched into the Dutch Republic, taking city after city until only Amsterdam and The Hague remained. In one last desperate measure, the Dutch broke open the dikes, ruining their own land in the process.

With Holland's lands devastated and French and English fleets raiding its shipping, the Dutch leader, Jan de Witt, having till now valiantly led Holland's defense, brokered a treaty giving Louis some cities and paying his war expenses. However, this enraged the Dutch and an angry mob beat de Witt and his brother to death.

De Witt's death led to the accession of William III of Orange, who symbolized uncompromising resistance to the French. When urged by an English diplomat to give in to Louis XIV, William replied: *"My country is in great danger,*

but there is a sure way never to see it lost, & that is to die in the last ditch."

Led by William's staunch defense, the Dutch drove back Louis' army bit by bit.

Meanwhile, in the Third Anglo-Dutch War (1672-74), the Dutch fought the English to a standstill. In 1674, William made a separate peace with England and forged an alliance with Spain, Brandenburg-Prussia, Denmark, and Austria against Louis. William also married Mary Stuart, daughter of the future James II of England. It was a marriage that would have huge consequences on both the diplomatic history of Europe and England's constitutional history.

In 1678, against the wishes of his allies, William made peace with France, getting back all previously held Dutch lands while recognizing French claims to Franche Comte.

Meanwhile, Louis' war effort in Germany had been more successful. His great marshal, Turenne with only 20,000 men, beat an imperial army of 70,000. In 1674, under orders from Louis to teach his enemies a lesson, he devastated the Palatinate, which was a major blot on both Louis' and Turenne's records. In 1675 Turenne led his army on a rare winter march (below) to beat Brandenburg's army at Turkheim.

The next year Turenne was killed on reconnaissance. Louis' other great marshal, Louis de Bourbon, Prince de Condé, took over. However, worn out by years of warfare, he soon retired. After this, Louis' had no generals of Turenne's or Conde's caliber. In 1678, after six exhausting years of war, the remaining combatants signed the Treaty of Nijmegen, which gained Louis Franche Comte and some other lands in the North.

Louis' propaganda art.

While Louis attended many sieges from a safe distance, he never led his troops in battle. However, one might never guess this, since he constantly had himself portrayed in front of his armies in a series of remarkable tapestries he had done glorifying himself, such as this one showing him triumphantly entering Dunkirk after its fall in 1673

Louis at the "height of his glory". The 1680s saw Louis at the height of his power, as symbolized by officially moving his court to Versailles. However, glory came at a price-- a price Louis didn't notice his people were paying.

For one thing, Louis kept a huge peacetime army as a diplomatic weapon, driving taxes up and the economy down. While the partying went on at Versailles, peasants were reduced to making bread from acorns and roots, while some were driven to rebellion.

As a further blow, Colbert died in 1683, leaving Louis surrounded by "yes-men" in awe of the king and not daring to give him advice he needed to hear. The one minister with a mind of his own was Louvois, Louis' minister of war, and his only mantra seemed to be "war, war, war", just what Louis wanted to hear.

On top of these problems, Louis had revoked the Edict of Nantes in 1685, leading to the mass emigration of 200,000 Huguenots, weakening France even more.

War of the League of Augsburg (AKA The Nine Years War) (1688-97). Trouble started when Louis claimed certain German lands, saying they were his since they were dependencies of areas ceded to Louis by the Treaty of Nijmegen. This spawned Louis' Policy of *reunions*, annexing lands by decree of local *parlements (courts)*. Austria, preoccupied with the Turks, acquiesced, prompting Louis to seize the strategic fortress town of Strasbourg despite the lack of any evidence it had ever been French. Next Louis seized the fortress city of Luxembourg (June, 1684) leading to the Truce of Ratisbon (1684) that allowed him to keep lands he'd already taken by his reunions, but froze the borders against further annexations.

However, while Austria was still fighting the Turks, Louis seized the electorate of Cologne and the fortress of Philippsburg in 1688. This was too much, and the Grand Alliance of Vienna was formed between Austria, Britain, Spain, Savoy, and several German states. Thus Europe went to war once again.

On land, France kept winning very costly victories. Yet, no matter how often he was beaten, William III kept coming back to continue the fight. The war's heavy attrition forced Louis to draft French peasants to fill his ranks, thus driving the tax base even further down.

Though French soil was barely touched, the war was taking its toll. France was on the verge of collapse, with internal trade choked by hundreds of tolls and broken bridges. At the same time, enemy fleets were cutting foreign trade. And then, adding to France's misery, famine hit in 1694.

Louis raised his army to 450,000 and navy to 100,000 men. To pay for this he melted his own silverware and urged his subjects to do likewise.

France's coinage was depreciated and new offices were created and sold at a spiraling rate. As one courtier put it: *"Every time your majesty creates an office, God creates a fool to purchase it."*

While state revenue in 1697 was 81 million livres, Louis was spending 219 million, nearly three times that. With France bleeding to death, the Peace of Ryswick was finally negotiated. Louis XIV surrendered Luxembourg and most of the other Réunion territories, leaving him only 82 of the towns, villages, and hamlets he had taken since 1680.

The War of Spanish succession (1701-13)

For thirty-five years, Charles II of Spain had seemed on the verge of dying. This sad product of Hapsburg inbreeding couldn't talk until age four, was so weak he had to be carried around until age eleven, could not chew his food properly, and could not produce children. As king, he wasn't any kind of effective ruler, his only talent seeming to be the ability to stay alive year after year. For thirty years people had been betting on his coming demise, and somehow he kept beating the odds.

There were three main contenders to succeed Charles to the Spanish throne:

- Louis' grandson and Charles' great-nephew, Philip of Anjou;
- Joseph Ferdinand, Charles' great-nephew, and son of the Elector of Bavaria; and
- Archduke Charles, son of the Holy Roman Emperor, and Charles' great-nephew.

Louis was tempted to push Philip's claim, but saw how this could lead to war. Therefore, he negotiated the First Partition Treaty with England and the Dutch in 1698 whereby, if Charles died childless, Philip would get the

Kingdom of the Two Sicilies and some dependencies on the coast of Tuscany; the Austrian prince would get Milan; and Joseph Ferdinand would get Spain and its colonies.

Then, in 1699 young Joseph Ferdinand died of smallpox, leading to the Second Partition Treaty (1700). Louis' grandson Philip would still just get The Two Sicilies, Tuscan lands, and Lorraine, the Duke of Lorraine would get Milan, and Spain and the rest of its possessions would go to Archduke Charles II.

There was one problem with all this. The Spanish king had not been consulted in any of this. Furious at this arrangement, Charles willed everything to Philip of Anjou, Louis' grandson and his own great-nephew, thinking only a prince supported by a strong France could hold his empire together.

Louis was now caught in the dilemma of should he stand by the Second Partition Treaty or abide by Charles II's will and take the whole Spanish Empire for Philip. In the end, he decided to take Spain, and the Spanish people welcomed Philip V on his arrival as their lawful king.

It took him nearly 35 yrs., but, Charles II of Spain finally succeeded in dying on November 1st 1700, and Louis pushed his grandson Philip's claim to the Spanish throne. In response, Holland, England, Austria, and various German states allied against France and Spain. The War of the Spanish Succession was on.

It would be Louis' longest and bloodiest war.

By now Louis' best generals were dead and their successors, while competent, were too scared to move without the king's permission. Meanwhile, two brilliant generals emerged for the allies: England's John Churchill, Duke of Marlborough (rt.) and Prince Eugene of Savoy for Austria.

The allies had major strategic problems in coordinating their efforts:

- **The Dutch wanted to protect the Netherlands.**
- **Austria wanted to protect Germany.**
- **England had to be convinced that any continental involvement at all was in its interest.**
- **And someone had to commit to fighting in Spain.**

In order to keep the Grand Alliance together, Marlborough marched from the Netherlands across Germany to link up with Eugene, thus showing their commitment to protect all their allies. It was as much a diplomatic triumph as a military one.

They followed this up with brilliant victories at Blenheim (1704), Ramilles (1706) and Malplaquet (1709). The French, thrown on the defensive, dug in their heels to defend French soil, even drafting peasants to fill their depleted ranks. Surprisingly, they fought well in defense of their homeland.

Then England got a new Queen, Anne, who was sick of the war and wanted peace. At the same time, England's allies were getting increasingly nervous about a revived Hapsburg Empire if the Austrian candidate were to take the Spanish throne.

Therefore, the resulting Peace of Utrecht (1713) gave Louis's grandson the Spanish throne, but France and Spain could not be united under the same monarch.

96. THE ENGLISH REVOLUTION: (1603-88)

"The state of monarchy is the supremest thing on earth; for kings are not only God's lieutenants on earth, but even by God himself they are called gods."-- James I of England

"A king is a thing men have made for their own sakes, for quietness' sake. Just as in a family one man is appointed to buy the meat..."-- John Selden

Introduction: a century of change. As the Greek philosopher, Heraclitus, said, nothing is so constant as change. While history has always seen changes taking place, few times and places saw more dramatic changes in such a wide variety of areas ranging from fashions and diet to the Scientific Revolution as England saw in the 1600's. But nowhere were there more sweeping changes than in the realm of government. In 1600, the absolute monarch believing in the concept of Divine Right of Kings was becoming the most fashionable form of rule. By 1700, a new more democratic government with checks and balances between the executive (king) and legislative (Parliament) branches had emerged in England, setting the stage for modern democracies.

Background to the Revolution. There were three main factors that came to the surface in the reign of Elizabeth I (1558-1603) to set the stage for the English Revolution. For one thing, going back to the Magna Charta (1215) which itself drew upon even more ancient Anglo-Saxon traditions, England had a long tradition that no one, not even the king, is above the law. Secondly, Elizabeth reigned in a period of intense religious strife, both within England itself as well as triggering an expensive war with Spain. Finally, the 1500's and 1600's were a period of rampant inflation, which made monarchs everywhere increasingly desperate for money.

The convergence of these factors during Elizabeth's reign generated problems in two critical areas: money and religion. As far as money went, the Queen knew how to get money from Parliament while outwardly showing respect to that body's rights and privileges. However, such treatment gave Parliament a growing sense of its own power and importance, which it was unlikely to give up peacefully. Elizabeth also partly paid for her rising expenses from the struggle with Spain by selling up to one-fourth of the royal estates. This left her successors with even less of an independent financial base, which in turn made them more dependent on Parliament for funds, thus leading to fights over money.

In religion, Elizabeth skillfully maintained peace in England while much of Europe was embroiled in religious wars. She did this by grafting moderate Protestant theology onto Catholic style ritual and organization. She also blunted the ferocity of the religiously radical Puritans (Calvinists) by incorporating many of them into the hierarchy of the Church of England. However, this put many Puritans into positions of authority where they could demand more sweeping reforms beyond the Queen's lukewarm Protestantism. In addition, many of these Puritans were also members of the gentry (lower nobles) and middle classes who controlled the House of Commons in Parliament and voted on taxes. Thus the issues of religion and money became even more tangled.

Religious wars, which threatened everyone's peace and security, and inflation, which made maintaining armies too expensive for rebellious nobles, also combined to help with the rise of absolutism in Europe. This rising tide of absolutism would influence the Stuart kings of England to try to establish absolutism in their own realm in spite of popular opinion. A less skillful and diplomatic ruler than Elizabeth would have trouble dealing with these new forces rising up in England. Such an undiplomatic ruler succeeded Elizabeth in the person of James I (1603-1625).

While Elizabeth had so skillfully kept the issues of money and religion in check, James' absolutist beliefs and abrasive personality brought them to the surface. As far as religion went, James fought the largely Puritan Parliament to keep the Church of England's Catholic style ritual, decorations, and hierarchy of clergy, over which he as king had control. In money matters, king and Parliament clashed over James' growing requests for money to support his lavish lifestyle. He also angered the middle class by raising customs duties, one of his main sources of revenue, to keep pace with inflation. While James and Parliament never completely broke with one another over these issues, their constant squabbling did set the stage for the revolution that was to follow.

Pattern of events (1625-88). While the individual events of the English Revolution could be somewhat involved and complicated, they did fit into a basic pattern. Parliament and the ruler of England would clash over the issues of religion and taxes as the government became less decisive and/or reasonable. This would trigger a reaction by Parliament that would bring in a new ruler, and then the process would start all over again. This cycle would repeat itself three times over the next sixty years, with each successive stage feeding back into

the aforementioned cycle as well as into the next stage.

The first stage would see England plunged into civil war (1642-49) that would result in the beheading of Charles I and the rise of the Puritans and Parliament to power. In the second stage, continued fighting over religion and money, this time between Parliament and its army, would bring in military dictatorship under Oliver Cromwell in the 1650's. After Cromwell's death (1658) would come the third stage with the restoration of the monarchy (1661-88). However, the old conflicts over money and religion would resurface in the reign of James II and lead to his overthrow by Parliament with the help of William III and Mary of Holland in 1688.

This time, Britain would resolve its cycle of conflicts in what is known as the Glorious Revolution (1688) This established a constitutional monarchy where the law is above the king, not the other way around as often happened in absolute monarchies. The Glorious Revolution would have three important results. First of all, it would lead to the political triumph of the rich middle class and nobles in Parliament which had the sole right to grant taxes for one year at a time, thus forcing the king to call Parliament each year if he wanted taxes. Also, in order to keep the king from packing Parliament with his own men for an extended period of time, Parliamentary elections were to be held every two years. While the Glorious Revolution resulted in a political victory for a narrow upper class oligarchy, it opened the way for further reforms over the next 200 years to make England a more truly democratic society.

Second, the Glorious Revolution gave all Englishmen a Bill of Rights guaranteeing such civil liberties as speech, assembly, religion (except for Catholics and Unitarians at this time), and due process of law. Both the political and civil liberties gained by the English would help lead to the French Revolution which in turn would spread the ideas of democracy across Europe and the globe.

Third was the establishment of the Bank of England (1694), which was modeled after the Bank of Amsterdam. This national bank would both provide the government with the funds it needed while repaying its loans with interest. This helped foster a more prosperous economy and encourage more investment in the bank, which in turn helped provide the government with more funds, and so on. This feedback of growing profits would eventually provide Britain with the money to start the other revolution that would spread worldwide: the industrial revolution. had plunged into civil war.

JAMES I, CHARLES I, AND THE ROAD TO THE ENGLISH CIVIL WAR (1603-1642)

James I (1603-25) Elizabeth I's successor, James I (who also ruled Scotland as James VI), was much more overbearing and prone to make enemies than Elizabeth had been. He lectured Parliament on the Divine Right of Kings and even wrote a treatise on it, *The Trew Law of Free Monarchies*. Such an attitude did not set too well with Parliament. James' abrasive manner, absolutist beliefs, more Catholic concept of what the Church of England should be, and demands for money to support his lavish lifestyle made him many enemies who dubbed him the "most learned fool in Christendom."

In religious matters, the king headed the High Commission, which exercised powers of censorship and excommunication and appointed the higher clergy who in turn chose the local clergy. News of the outside world came mainly from the clergy who got their news from the higher clergy and ultimately the king. As Charles I: put it: "People are governed by the pulpit more than the sword in times of peace." No wonder that religion became the main focal point of trouble at this time. There was also the issue of observing the Sabbath. Puritans felt that Sundays should be reserved for strictly religious activities and discussions. The king, fearing that such discussions might breed revolution, encouraged more frivolous sports on Sundays to keep people militarily fit and harmlessly occupied. Such a policy outraged the Puritans and turned them further against the king.

A cup & ball festival, the sort of fun the king would like to see the Puritans indulge in on Sundays.

Money was the other big source of conflict, and the House of Commons in Parliament was the primary battlefield. Among Parliament's most jealously guarded liberties was the right to grant taxes. This

had not been such a vital issue when kings could largely get by on the revenue from their estates, various feudal fees, and the right to sell monopolies and titles. However, inflation further reduced the value of the royal estates after Elizabeth sold a quarter of them, and James' own extravagant lifestyle and the rising cost of warfare in the 1500's and early 1600's led to growing friction between king and Parliament over money.

Parliament then was not so democratic in makeup as today. Even the House of Commons consisted solely of gentry (merchants and lower nobles) with an annual income of at least 40 shillings, a sizable sum back then. The rights and privileges they jealously guarded and fought for, such as free speech and immunity from arrest and flogging, were reserved for them alone, not the lower 90% of society. As one Member of Parliament put it: "He that hath no prosperity in his goods is not free." Still, the rights and privileges Parliament fought for and won in the 1600's set a precedent, and eventually would extend to all of society.

James did have one growing source of revenue: customs duties from a rapidly expanding foreign trade. In order to take advantage of this, James raised the taxable value of various commodities to keep up with their real market value, which had risen due to inflation. Naturally, the merchants in Parliament disliked this tactic and disputed James' right to revise those values without Parliament's consent.

Another problems for James was the lack of an efficient bureaucracy such as was developing in continental states. Taxes were collected by tax farming, where local merchants paid a lump sum to the king in advance and then collected however many taxes they could get away with. This, of course, led to lower royal revenues, more corruption, and rising tensions.

Thus the stage was set for a conflict between the king on one side and Parliament and the Puritans on the other. During James' reign, relations with Parliament were generally stormy. Constant haggling over money and such religious issues as the existence of bishops in the Church of England would reach fever pitch and then subside with an occasional compromise to patch things up. There was even a temporary alliance between king and

Parliament when a proposed marriage alliance with Spain (which was very unpopular with Parliament) fell through and got England involved in the broader conflict known as the Thirty Years War. For the time being, this drove king and Parliament together against the common Catholic enemy. However, the overall situation was deteriorating, and by James' death in 1625, relations between the two parties were, at best, strained.

Van Dyck's most famous portrait of Charles I (1625-49). Van Dyck was an especially popular portrait artist, largely because, instead of using the usual 6:1 ratio of body to head size, he used a 7:1 ratio. This made his subjects, such as Charles, appear taller and more regal. In reality, Charles was supposedly somewhat short and dumpy.

It was said that James steered the ship of state for the rocks, but left it for his son, Charles I, to wreck it. Charles was undiplomatic, insensitive to public opinion, and a weak monarch who let events get out of control and send England drifting toward civil war. In addition to dealing with inflation, Charles, like James, was caught between the rising aspirations of Parliament and the Puritans on the one hand and his own ideas favoring Catholicism and absolutism on the other. He even resorted to forcing loans out of men and imprisoning those who refused to cooperate. In 1628 Parliament reacted by forcing him to sign the Petition of Right in which he agreed not to levy taxes without Parliament's consent, imprison free men without due process of law, or quarter his troops with private citizens. After this, he dissolved Parliament and ruled on his own.

For the next eleven years (1629-40) Charles managed to get by without Parliament by stretching various royal rights and fees to the limit. One of these methods was selling monopolies. Under this system only the man who bought a monopoly on a particular type of goods had the exclusive right to

sell or grant the right to others to sell those goods. This wreaked havoc with prices and caused a good deal of discontent, especially since the monopolists controlled a wide range of products including buttons, pins, dyes, butter, tin, beer, barrels, tobacco, dice, pens, paper, gunpowder, feathers, soap, lace, and hay to name just a few. Another method was extending the traditional ship's tax (previously levied only on coastal towns) to the whole countryside. As unpopular as these measures were, they raised enough money to keep the king going.

Charles might have continued like this indefinitely, but in 1637, he tried to impose the English Prayer Book on the Scots and triggered a revolt instead. Unfortunately for Charles, many of the Scots were battle-hardened veterans from the Thirty Years War who made short work of his largely untrained rabble. Desperately in need of money to continue his war, Charles called Parliament in 1640. However, after three weeks of arguing with Parliament over the last eleven years' religious and monetary policies, the king dismissed this "Short Parliament." However, the Scots did not go away. Instead, they occupied part of the north and made Charles promise a large sum of money every day until a final settlement was reached. Charles had no choice but to call Parliament again. This Parliament, known to history as the Long Parliament, would sit for over a decade and preside over a civil war and the end of absolute monarchy in England.

Charles, desperate for money and support to take care of the Scots, initially agreed to Parliament's demands: to call Parliament at least every three years and not to levy taxes or dismiss Parliament without its consent. He even let Parliament execute one of his chief ministers, Sir Thomas Wentworth, Earl of Strafford.

However, there was hardly peace between king and Parliament, only an uneasy truce until November 1641 when a revolt broke out in Ireland, with Irish Catholics killing thousands of English and Scottish Protestants who had taken their best lands. An army was needed, but neither king nor Parliament was going to allow the other to command such an army. When Parliament refused Charles his army, he sent troops to arrest five Parliamentary leaders. When they found refuge in London and support

from other towns, Charles left London, and England had plunged into civil war by August 1642.

The “Most Learned Fool in Christendom”

James I (1603-25). Since Elizabeth never married, and thus had no direct heirs, she was succeeded by James I, who was her first cousin twice removed and the son of Mary, Queen of Scots, who also ruled Scotland as James VI. As a result of this union of England and Scotland, the term Great Britain was first used to describe England.

James didn't look or act much like a king. His tongue was too big for his mouth and he was pop-eyed, giving him a constant expression of anxiety or apprehension. He wore padded clothing to protect himself from assassins, while on the hunt, he tied himself into the saddle to keep from falling off his horse. He also had the disturbing habit of slashing wildly at the carcasses of fallen game with his knife and throwing the entrails about.

In fairness to James, his problems and idiosyncrasies were not all his fault. For one thing, the violent family and court history of Scotland made him understandably paranoid. Also, in Scotland, speaking face to face, including making personal threats, was an effective way to rule where there weren't so many people to deal with. In England, with its larger population, such tactics and long speeches were not so effective. Also, making personal deals and favors, which worked in Scotland, were an unpopular tactic in England. Finally, since there was no real credit economy developed in Scotland, James didn't understand the financial situation in England.

Parliament

Parliament was originally any meeting between the English king and subjects he had summoned to discuss whatever issues he had at the time, most commonly local taxes.

In 1295 Edward I summoned what became known as the Model Parliament, since it consisted of members of all three estates (clergy, nobles, and townsmen). The purpose was to discuss taxes for the whole kingdom rather than having to go around and summon a bunch of local parliaments. Although this served as the model makeup for future parliaments, the king summoned and dismissed parliament at his discretion. For example, between 1603 and 1629, Parliament only sat for a total of 4.25 years. Thus the eleven year hiatus imposed by Charles I (1629-40) wasn't as unusual as it might seem today.

Parliament sat in two groups: the House of Lords, consisting of the upper nobles (aka Peers) and the House of Commons consisting of lower nobles and rich townsmen who together were known as the Gentry, although this was not legally a class, but a property qualification for being a member of the House of Commons. Unlike in other countries, noble titles could not be bought in England. By the same token, there was no stigma for nobles, especially lower nobles, to engage in trade and business. These two factors blended the lower nobles and rich townsmen into a more uniform group who tended to invest more of their money in business enterprises than did their counterparts on the continent, since they couldn't waste it on noble titles anyway. Another leveling element was the fact that everyone but the clergy paid taxes, thus creating more common interest between classes. All this made the gentry a particularly powerful and dynamic group, especially by the 1600s when inflation and other factors forced England's rulers to depend increasingly upon Parliament to meet their expenses.

The Royal Court Politics in Seventeenth Century England

At the time of James I, the entire royal bureaucracy of England consisted of two secretaries of state and 25 clerks. As a result, the king handled the most trivial matters, including family squabbles, which led to huge delays in getting things done. This also led to a rush of people to the court at London, which swelled to a population of around 2,000 courtiers and court employees. Between 1560 and 1580 business for royal courts quadrupled, and doubled again by 1640. Judges were so overloaded and had to rush through cases so that they probably could spend on average only twenty minutes per case.

On top of that, anyone out in the country wanting something done had to come to London. But the crush of other people with their own business made it essential to find an influential patron with strings to pull. Of course, such services didn't come free, so bribery and corruption were rampant at court.

Old and Outdated Laws

Ship money was a tax going back to the middle Ages when England's ports, such as the five seaports, known as the Cinque Ports (Hastings, Romney, Hythe, Dover, and Sandwich) paid their taxes to the king by providing him with transport and naval service. By the 1600s, however, England had its own specialized navy, rendering the ports' services somewhat outdated. In 1634, when he was trying to get by without Parliament, Charles I extended the tax to all of England, the logic being that the navy protected all of England, so all of England should pay for it. Although meeting widespread resistance, ship money provided enough cash for the king until he got into a war with the Scots.

Outdated laws and customs that were still on the books provided Charles another avenue for raising money. For example, an old medieval law provided that any noble worth over £40 had to be knighted at king's coronation or pay a fine. Enforcement of this law alone raised £165,000 for Charles.

Such laws are nothing unique to seventeenth century England. Virtually every legal system has old laws on the books that have become absurdly obsolete, but no one bothered to get rid of them. Here are a few examples from the U.S.

- In Marshalltown, Iowa, horses are forbidden to eat fire hydrants.
- In Devon, Connecticut, it is unlawful to walk backwards after sunset.
- In Denver it is unlawful to lend your vacuum cleaner to your next-door neighbor.
- In Santa Clara, California it is forbidden to dedicate parking spaces to the patron saint of television.
- In Ohio, if you ignore an orator on Memorial Day to such an extent as to publicly play croquet or pitch horseshoes within one mile of the speaker's stand, you can be fined \$25.00.
- It is illegal for a man to give his sweetheart a box of candy weighing less than fifty pounds in Idaho. (Maybe they wanted him to give her potatoes instead.)
- In Urbana, Illinois, it's illegal to bring monsters inside the city limits or urinate in your neighbor's mouth.
- Hunting camels or plowing fields with an elephant is prohibited in Arizona.

Of course, most of these laws originally had some rationale for being passed. For example, the law against hunting camels in Arizona goes back to the aftermath of the Mexican War (1846-8) and the Gadsden Purchase (1854) when the U.S. had taken over the desert Southwest. Since a transcontinental railroad was decades away, Secretary of War, Jefferson Davis (and later president of the Confederacy during the Civil War) sent people to the Middle East to buy camels and form the U.S. Army Camel Corps for running caravans and chasing Indians across the desert.

Unfortunately, when the Civil War began, troops were pulled back east, and the camels were either sold to mines and circuses or turned loose in the desert where they roamed until they had died off by the early twentieth century. Thus the law against hunting them.

Natural history note: Camels apparently evolved in the Western Hemisphere millions of years ago and then spread across the Alaska-Siberia land bridge a million years ago. While some varieties, such as the llama, survived in South America, they seem to have died off in North America about 15,000 years ago, partially the result of Native Americans hunting them. If only Arizona had that law 15,000 years ago.

Laws against monsters were probably the result of continued belief in creatures such as the Hodag (above), a 200-pound, seven-foot-long, lizard-like beast covered with horns that is supposedly a resurrection of the restless spirit of dead lumber oxen. . The Hodag was first seen by Eugene Shepard in 1893 in the woods outside of Rhinelander, Wisconsin. When he failed in an attempt to capture it, he blew it up with dynamite (in self-defense, of course). His second attempt in 1896, with a backup crew of lumberjacks, was more successful, cornering a Hodag in its den and knocking it out with a chloroform sponge on a pole. An early specimen of the Hodag is on display at the local Logging Museum.

Monopolies in 17th century England

Selling royal monopolies was a lucrative source of income for both the Stuart monarchs who sold them and the men who bought and squeezed exorbitant profits from them. Christopher Hill, in his book, *A Century of Revolution*, gives an exhausting, if not exhaustive, account of the various monopolies one would encounter in England at this time:

“It is difficult for us to picture to ourselves the life of a man living in a house built with monopoly bricks, with windows (if any) of monopoly glass; heated by monopoly coal (in Ireland monopoly timber), burning in a grate made of monopoly iron. His walls were lined with monopoly tapestries. He slept on Monopoly feathers, did his hair with monopoly combs. He washed himself with monopoly soap, his clothes

in monopoly starch. He dressed in monopoly lace, monopoly linen, monopoly leather, monopoly gold thread. His hat was of monopoly beaver, with a monopoly band. His clothes were held up by monopoly belts, monopoly buttons, monopoly pins. They were dyed with monopoly dyes. He ate monopoly butter, monopoly currants, monopoly red herrings, monopoly salmon and monopoly lobsters. His food was seasoned with monopoly salt, monopoly pepper, monopoly vinegar. Out of monopoly glasses he drank monopoly wines and monopoly spirits; out of pewter mugs made from monopoly tin; he drank monopoly beer made from monopoly hops, kept in monopoly barrels or monopoly bottles, sold in monopoly-licensed ale-houses. He smoked monopoly tobacco in monopoly pipes, played with monopoly dice or monopoly cards, or on monopoly lute-strings He wrote with monopoly pens, on monopoly writing-paper; read (through monopoly spectacles, by the light of monopoly candles) monopoly printed books, including monopoly Bibles and monopoly Latin grammars, printed on paper made from monopoly-collected rags, bound in sheepskin dressed in monopoly alum. He shot with monopoly gunpowder made from monopoly saltpeter. He traveled in monopoly sedan chairs or monopoly hackney coaches, drawn by horses fed on monopoly hay. He tipped with monopoly farthings. At sea he was lighted by monopoly lighthouses. When he made his will, he went to a monopolist. (In Ireland one could not be born, married, or die without 6d to a monopolist.) Peddlers were licensed by a monopolist. Mice were caught in monopoly mousetraps. Not all these patents existed at once, but all come from the first four decades of the seventeenth century. In 1621 there were alleged to be 700 of them.”

THE ENGLISH REVOLUTION: FROM CIVIL WAR TO MILITARY DICTATORSHIP (1642-60)

"Trust in God and keep your powder dry."-- remark attributed to Oliver Cromwell

The English Civil War (1642-45). Few people on either side wanted civil war. However, the issues involved were so important and the differences between the two sides so great that each party felt itself forced into war. Although both sides had support from all classes, one can generalize about where each side got its support. The king's centers of power were in the more agricultural regions of the North and West. His main supporters tended to be the upper nobles, known as *peers*, from the House of Lords. In the war they were referred to as *Cavaliers* since they mainly fought as cavalry. Parliament's support came mainly from the gentry concentrated in the towns and ports in southeastern England. They were known as *Roundheads* for their short haircuts, as opposed to the long hair of the Cavaliers. (In fact, many parliamentary leaders, being from the upper classes, kept their hair long.) Both sides also looked outside of England for help. The king hoped for support from the Catholic Irish, while Parliament was allied to the Scots. Since the Roundheads controlled the ports and the navy, the king was largely cut off from his Irish allies. Meanwhile, the Scots could provide very effective aid to Parliament.

Historians used to think that both sides fought poorly in the early stages of the war, since England, being an island, had no standing army and little in the way of a military since the Hundred Years War. However, recent research shows that both sides drew heavily upon veterans from the Thirty Years War and fought more effectively than previously supposed. Despite inferior manpower and resources, the king's forces did have superior cavalry, led by the king's dashing German nephew, Prince Rupert of the Rhine, and could more than hold their own against the Puritans in the early stages of the war.

The first battle, Edgehill (1642), was a bloody draw, probably cut short by lack of gunpowder. Both sides came out of this realizing the need for training, discipline, and supplies. Ultimately, Parliament's superior resources and the Puritans' greater willingness to submit to military discipline would be decisive in the war's outcome. It was here that one

of the key figures of English history first emerged: Oliver Cromwell.

Cromwell was an obscure country gentleman and stern Puritan, typical of many gentry who sided with Parliament. After Edgehill, it was apparent that the Puritans needed better cavalry to face Prince Rupert's wild cavalry charges. Cromwell raised and trained such a regiment, later known as Ironsides for its steadiness in battle. Rather than taking mercenaries drawn from the dregs of society, Cromwell relied mainly on men of a religious nature and committed to the cause instead of looting and plundering. Their first test came in 1644 at Marston Moor. Ironsides held fast against the cavaliers, and the king's forces were crushed.

In January 1645, Parliament passed an ordinance to form the New Model Army. Contrary to the myth of being a body of "Bible warriors," the New Model Army was made up of draftees and mercenaries fighting for money. However, following Cromwell's example, it was a highly trained and disciplined professional force with regular pay and equipment. In the 1650's it was probably the best army in Europe. Later that year, it met and destroyed the king's last army at Naseby. Charles surrendered to the Scots hoping to turn them against Parliament. However, they turned him over to Parliament.

More bickering and a second civil war (1645-1648).

Charles was right in assuming he could split the victors, and the reasons for that split were largely the same reasons that had first led to civil war: money, religion, and government. The civil war, like most wars, had been expensive, and Parliament did not have the money to pay the New Model Army it had raised. It tried to disband the army, promising to repay it later, which did not set too well with the troops, who refused to disband. Instead, they set up a General Council of the Army composed of generals, officers, and "agitators", elected from the rank and file. This council took custody of the king, occupied London, and forced 11 parliamentary leaders out of the House of Commons.

Religion was another point of controversy between Parliament and army. Both parties were Puritans, but of somewhat different types. Most of Parliament wanted a state run, or Presbyterian, church, while most of the army, including Cromwell, wanted independent churches with freedom of religion. This

was what many of them had fought for, and they were not about to give it up to Parliament.

Finally, there was the issue of what sort of government the victors would establish. Parliament and most of the officers, including Cromwell, were property owners who felt that they were most fit to rule since they had so much property to be responsible for. The rank and file in the army, sensing their power, pushed for a much more radical and democratic government. The most radical of these, the Levelers, wanted the vote for all men, a bill of rights, and the abolition of the monarchy and House of Lords. A meeting of the General Council of the Army led to a deadlock between the officers and common troops. Cromwell ended the discussion and ordered the agitators back to their regiments, having one of them shot in order to convince the others to submit.

At this point, events forced army and Parliament to reunite, because Charles had escaped and raised the Scots and English royalists in revolt with promises of establishing a Scottish style Presbyterian Church if he regained his throne. This second civil war was a short and decisive affair. Cromwell, leading the New Model Army, annihilated any opposing Scottish and royalist forces in quick succession.

Cromwell's Dictatorship (1649-60). Once this war was over, Cromwell and the army moved just as decisively to resolve the problems in London. First, there was Parliament, which the army especially disliked, since some Parliamentary members had entered into negotiations with Charles to restore the monarchy. This led to Pride's Purge, named after a Colonel Pride who used the army to expel some 100 Presbyterian members. This left a "Rump Parliament" of about 60 members who were more agreeable or submissive to the will of Cromwell and the army. Next came the king, who was tried for treason and executed on January 30, 1649. Bishops

and the House of Lords were abolished and the religious independents prevailed.

However, the democratic reforms that the Levelers and much of the army hoped for never materialized. Resulting mutinies were quickly put down and Leveler demonstrations led to the arrest of their leaders. At first, Cromwell ruled through the Rump Parliament and a government known as the Commonwealth (1649-53). However, frustrated by what he saw as Parliament's lack of fervor for his type of rule, he established a more blatant dictatorship known as the Protectorate with himself as Lord Protector.

Outside of England, Cromwell faced a war with Scotland, which he conquered and ruled with some moderation since the Scots were fellow Protestants. Catholic Ireland, another enemy, was not so lucky. Cromwell's conquest of Ireland was methodical and brutal, leaving wounds that still have not healed today. Like it or not, Scotland and Ireland were incorporated into the greater Commonwealth of Britain, something no English king had been able to do. Cromwell also had an aggressive foreign policy outside of Britain, fighting successful wars against the Dutch and Spanish and making England a military and naval power to be reckoned with.

Inside England, people felt Cromwell's heavy hand as well. His wars, standing army of 30,000 men, and navy required taxes three times higher than any which James I and Charles I had ever imposed. Churches were more locally controlled, but people were expected to live good religious lives. Theaters, taverns, and racetracks were all closed down. People dressed in somber colors to reflect the mood of the ruling regime. Life under Cromwell seemed like Calvinist Geneva, except on a much grander scale. Rather than put up with this regime, many cavalier families, such as the Washingtons, Madisons, and Monroes, left England for the American colonies, especially Virginia, much like the Puritans had fled to New England from royal repression thirty years earlier. These two ways of life, the aristocratic nobles in the South and the capitalist Puritans in the North, would take root and clash with one another two centuries later. Thus the American Civil War was largely an extension of the English Revolution.

Oliver Cromwell died on September 3, 1658. He was certainly one of the greatest figures in English

history, although his motives and the nature of his greatness are still disputed by historians. However, no one of his caliber emerged to take firm control of England after him. His son Richard tried, failed, and resigned. This led to various generals wrangling over power, but people in general were tired of the strict Puritan rule. They also longed for a king, since that was the traditional ruler for a country. Finally, a certain General Monk led the army in Scotland to London, restored the Long Parliament, which asked Charles II, Charles I's son who had escaped to France, to come back as the king. England's experiment in government without a king was about to end.

“England’s Wolf with Eagle’s Claws”

Prince Rupert of the Rhine, Charles’ nephew and the Cavaliers’ most brilliant cavalry commander was the son of James I’s daughter Elizabeth and the ill-fated Frederick of the Palatinate whose bid for the throne of Bohemia had started the Thirty Years War. He had spent much of his life in a Hapsburg prison where he studied cavalry tactics. He was only 22 when he assumed command of his uncle’s cavalry.

Rupert dressed flamboyantly and made enemies with his tactlessness. He also terrorized the English countryside with his raids, earning him the title “England’s wolf with eagle’s claws”. Outside London and a few other towns, little was safe from Rupert.

Rupert had a pet poodle that he had taught to dance to the following tune and then lift his leg to urinate:

***“Who name but Charles he comes aloft for him
And lifts his malignant leg for Pym.”***

*** John Pym was a Parliamentary leader.**

Roundhead propaganda claimed Boy was a witch, a witch’s familiar, or even the devil himself and that he was invulnerable to bullets, able to catch bullets in his mouth, and could himself invisible to spy on the enemy.

His supposed invincibility was disproven when he was killed by enemy fire at Marston Moor in 1644. Not surprisingly, Puritans celebrated his death.

Despite his prissy little dog, Prince Rupert was one of the best cavalry leaders of the war, forging the inexperienced cavaliers into an excellent fighting force that fought in three ranks and charged as shock cavalry in the manner the Swedes had learned from Polish hussars in Eastern Europe.

First blood at Edgehill (1642)

***Trained bands.* One of the myths of the English Civil War was that neither side knew how to fight well at its start. However, in addition to the large numbers of Scottish and Irish veterans from the Thirty Years War who took part, there were the “trained bands” of militia (below) the king had required to train. While they weren’t hardened veterans, they weren’t totally raw recruits either, and they adapted to warfare fairly quickly.**

***At Edgehill,* the first major battle, there were about 14,000 men on each side, with the cavalry on the flanks where they could best maneuver. Theoretically, in such battles, the cavalry would come to grips first while the infantry was still**

moving up, and thus resolve their part of the battle first. Whichever cavalry won, was supposed to finish the battle by attacking the enemy infantry on their exposed flanks.

However, Edgehill assumed the all too familiar pattern where the victorious cavalry (in this case the Royalist Cavaliers led by Rupert) found it more appealing to loot the Roundheads' undefended camp than get their hands dirty from fighting lowly infantry. What they didn't see were two Roundhead cavalry regiments in reserve who did their job of attacking the Royalist infantry in the flank.

Thus the day's fighting ended in a draw, probably because both sides ran out of gunpowder (something neither side would openly admit).

Most likely shortages of powder cut short several battles in the English Civil War.

The Puritans could claim one success at Edgehill: the capture of the King's flag.

The two armies spent the next day staring at each other, neither with the stomach to resume the fight. Edgehill did wake up many, especially the rank and file, to the awful realities of war.

Part of the tragedy of civil war is that it often divides families. At Edgehill there were two fathers on the king's side fighting against their two sons on the other side.

Although a draw, Rupert's subsequent move on London put Parliament into a panic, causing it to try to negotiate with Charles, but the king refused. Therefore, Parliament had London fortified with eighteen miles of packed-earth fortifications, including a moat that was nine feet deep and wide, and 24 star-shaped forts connected by walls and redoubts, etc. No trace of it currently remains.

Stalemate (1643-4)

After Edgehill, the war turned into a series of localized conflicts, largely because the trained banks refused to leave their home counties to fight a broader war. Skirmishes and sieges of manor houses became the most common type of fighting.

With their men gone to war, women often had to lead the local defense. For example, Lady Harley of Brampton organized a garrison and led its defense for 6 weeks, while a certain Mrs. Purefoy with only 4 men, 3 maids, and her daughters shot 3 captains and 15 troopers before Prince Rupert finally took the place. Impressed by Mrs. Purefoy's courage, Rupert showed the defenders rare mercy.

By 1644 both sides were exhausted and desperately seeking outside help. With France still preoccupied with the Thirty Years War and the accession of the 4-year old Louis XIV to the French throne in 1643, Charles could expect little help from France. In addition to the Irish army left over from the revolt in 1640, the Irish sent 17,000 more troops to the king. However, in order to avoid Parliament's navy, they arrived piecemeal and then were parceled out among various Royalist armies. Complicating matters was the fact that many of these soldiers were English Protestants who mutinied against the king and/or deserted to the other side.

Parliament had an easier time getting 22,000 Scots after Pym's treaty gave them religious

concessions, promising, among other things, to make the Church of England a Presbyterian church on the Scottish model. While Pym's treaty, would provide the means to win the war now, it also laid the seeds of dissension between Presbyterians and Independents after the war.

Stretching the sinews of war. In 1642 when the war started, motivated recruits were relatively easy to get. But by 1643 and 1644 many of the initial recruits were dead or gone and were hard to replace with volunteers. Therefore, both sides resorted to conscription, at first drafting the dregs of society. However, they typically deserted and plundered the countryside, causing peasants to form vigilante bands of "clubmen" who attacked any soldiers they caught. Since the trained bands resisted leaving their home counties, Parliament started to draft laborers and peasants, which made the war very unpopular.

Part of the problem was the lack of money. Despite its superior resources, Parliament had as much trouble feeding, clothing, and equipping its army as did the king, who set up factories for clothes and shoes, while getting arms and powder from overseas.

Getting gunpowder was especially a problem, in particular its active ingredient, saltpeter or potassium nitrate, which was a bi-product of bird droppings or human urine. Previously, royal monopolists had the right to enter any man's premises and dig in his henhouses, dovecotes, or privies. Although this led to widespread resentment, Parliament resorted to similar methods during the civil war.

In lieu of money Parliament promised to give its veterans Irish lands. Another extremely unpopular practice by both sides was quartering troops in people's homes. By 1644, the desperate measures both sides were being forced to use were driving the war to a crisis.

The Rise of Oliver Cromwell

Cromwell's early life. (1599-1658) As with any famous person in history, especially those with humble origins, there are numerous apocryphal stories about Cromwell. In one legend he was stolen from the cradle by a monkey, and in another he gave baby Charles a bloody nose over a toy when the royal family was visiting Cromwell's grandfather.

Born in 1599, he was virtually unknown before the Civil War, an obscure country gentleman who married a rich leather merchant's daughter, Elizabeth Bourchier, and struggled to raise a family of six children on a modest estate. In 1631, he had to sell his estate and to rent a farm.

He first attended Parliament in 1628, the year of the Petition of Right. His first recorded speech was in defense of his old teacher who had been reprimanded for criticizing the "popery" of the Church of England. (It was quite typical for such local issues to take up Parliament's time.) Cromwell was also involved in local politics, in particular leading a fight against the Earl of Bedford who was enclosing and draining some fenlands to create more farmland, but less hunting and fowling for the poor. Because of this campaign Cromwell was called "Lord of the Fens".

In November 1640 he went back to Parliament along with 18 of his kinsmen. Therefore, he was present at the crisis that led to the outbreak of civil war. While becoming more actively involved, he was by no means a major player yet.

After Edgehill (1642) Cromwell went home and formed a cavalry regiment, later called Old Ironsides by Prince Rupert. Its members were highly trained and inspired with a religious fervor that some thought bordered on fanaticism. However, religious they may or may not have

been, they were effective in much the same way the Union cavalry could finally stand up to Confederate cavalry two years into the American Civil War.

By 1644, Cromwell was calling for more decisive action from his superior officers whom he could publicly criticize, since he was a Member of Parliament. He also supported the Self-Denying Ordinance where a Member of Parliament couldn't also be an officer in the army. At the same time, all Peers were removed from commands since they couldn't renounce their hereditary titles and positions in the House of Lords, while members in the House of Commons could resign from Parliament and keep their commands, which is what Cromwell did.

*"God made them as stubble to our swords":
The Battle of Marston Moor (1644)*

On July 2nd, 1644 a Parliamentary army of 27,000 troops met an army of 17,000 Cavaliers under Prince Rupert at Marston Moor. The Royalists broke for supper at 6PM, thinking it was too late to fight. The Roundheads, however, weren't hungry and attacked. Cromwell's Ironsides drove Rupert's cavalry back, Cromwell himself being wounded in the neck.

Meanwhile, on the other flank, the Royalist cavalry, using the Swedish tactic of mixing 500 musketeers in with 2,000 cavalry, drove off the Parliamentary cavalry. True to form, the Cavaliers broke ranks to loot the enemy camp. Having driven off Rupert, Cromwell and Ironsides swung across the field and hit the Royalist infantry in the rear. One Royalist regiment, known as Newcastle's lambs or the Whitecoats for their undyed woolen coats, had vowed to fight to victory or until their coats were stained red with their own blood. They fought and died to the last man.

Much like Gettysburg did in the American Civil War, Marston Moor, marked the turning point in the English Civil War. There was still plenty of hard fighting and bloodshed left, but the tide had definitely turned.

A dog's death. Among those killed at Marston Moor was Rupert's dog, Boy, whom he apparently forgot to tie up before the battle. Puritans, who hated Rupert, rejoiced at Boy's death, claiming the dog had been a witch's familiar.

The New Model Army and Victory (1645)

In a final push toward victory, Parliament created the New Model Army of 14,000 infantry, 6000 cavalry, and 1,000 dragoons, mobile musketeers who traveled on horseback but fought on foot. Generally, one dragoon in four would hold the horses while the others formed a skirmish line, fired a few volleys to slow the progress of the enemy, and then rode off.

The new general, Thomas Fairfax, was slight, self-effacing, and quiet, but of iron will. He demanded iron discipline and regular pay for his men, which encouraged experienced veterans to re-enlist. The New Model Army generated a myth of being highly dedicated and religious men, since it was largely modeled on Cromwell's regiment, Ironsides. In reality it was a professional army motivated more by regular pay than religious or political conviction. In fact, Parliament resorted to forcible conscription, even kidnapping men off London streets in broad daylight.

Dutch and Swedish influence can be seen in the army's organization and its regular equipment and uniforms, in England's case red. At first, it had one pike man for every two musketeers, until flintlock muskets became standard issue for all in 1685. Each cavalry trooper carried a sword, two

pistols, a helmet, and a breast and back-plate. Around 1650, the helmet and armor would be replaced by a hat and coat of buffalo hide.

Following the lead of other countries, a modern officer corps and chain of command were also put in place. Similarly, the artillery was also put on a firm basis with standard organization.

The New Model Army proved its worth in 1645 by crushing Charles at Naseby. As usual, Rupert pursued too far while Cromwell came round and hit the Royalist infantry in the rear to win the battle. Next year, Charles surrendered to the Scots, hoping to split the victors.

The Army as the radicals of the revolution

If the English Revolution had a radical element corresponding to the Sans Culottes in the French Revolution or the Soviets in the Russian Revolution, it would have been the army rank and file, more specifically the faction among them known as the Levelers. Therefore, when the Presbyterian majority in Parliament moved to impose their style of church on all of England, there was widespread dissent among the troops who had fought for religious freedom. A multitude of pamphlets, sermons, and discussions to stir up new ideas led some preachers to expand religious equality to political and social equality as well.

In fact, the army was split into two groups of Independents: those, such as Cromwell and many army officers, with a solely religious agenda, and those, known as the Levellers and led by John Lilburne, who combined religious and political agendas. A few, possibly influenced by the pacifist Quakers who let women preach, even advocated equal rights for women. New elections in 1645-6 to replace members of Parliament expelled or lost during the war led to a more vocal group of

Independents in Parliament, although Presbyterians still held the majority.

Besides pushing for a more radical leveling of society, the troops pushed for execution of the king. This would prove both shocking and unpopular with the general populace who couldn't imagine their society without a king. It also showed that the radicals in the English Revolution, much as in the French and Russian revolutions, were somewhat out of touch with the feelings of mainstream society. Therefore, it wasn't long before pamphlets started appearing that, as Charles had foretold, portrayed him as a martyr of the people.

Caught in the middle of this was Cromwell, who favored freedom of conscience, but also had conservative political and social views that clashed with the more radical Levellers. Seeing monarchy, although not divine right of kings, as a reasonable form of government, he entered into negotiations with the king, which lost him and his followers the confidence of the rank and file troops, who started calling the officers Grandees (i.e. nobles).

The Trial and Execution of Charles I

"We shall cut off the king's head and the crown with it."--Oliver Cromwell

"I am a martyr of the people."--Charles I at his execution.

Charles trial by Parliament, much like the conciliar movement that solved the Great Schism in the early 1400s, raised a very real legal question. As the king constantly pointed out, if he indeed was the head of state and appointed by God, who on earth had the authority to try him? This was the crux of his defense, not even recognizing the authority of the court to try him,

and thus refusing to cooperate with the proceedings. This attitude also largely sealed his fate.

Cromwell, who was the third to sign Charles I's death warrant, did a bit of arm-twisting to pressure other members of Parliament to sign as well. Still only 59 of 135 Members of Parliament signed it, maybe because the other 75 members had been purged.

Charles I's execution (1/30/1649) was much less popular than Cromwell and the radical Puritans had anticipated. At the same time, another anti-royalist revolt, the Fronde, was raging in France, although ultimately with very different results from its English counterpart.

Cromwellian England from Monarchy to Military Dictatorship

The palace at Whitehall where Cromwell held court Cromwell's government. Cromwell did not see himself as a political revolutionary and instead strove for normalcy in government. He made continuous efforts to maintain the rule of law through Parliament, but felt constantly frustrated by its unwillingness or inability to act decisively on matters he felt had to be dealt with decisively. At one point he referred to Parliament as more of a prayer meeting than a government. As a result, he constantly felt compelled to tighten his grip on government to make things run the way he thought they should.

For example, soon after the execution of the king, he faced the climax of the crisis with the Levellers whose hopes for a democratic government were raised by the king's fate. When about 1,000 of them rose up to push for a more broadly based democracy, Cromwell dealt ruthlessly with them, arresting and executing eleven of their leaders.

When no one new stepped forward to lead them, the rest of the agitators backed down.

The Commonwealth (1649-53), with the "Rump" Parliament as the main governing body, was Cromwell's first attempt at establishing constitutional government. The next year he obliged every freeman over 18 to take an oath of loyalty to the Commonwealth, which was described as the "supreme authority of the nation...without any king, or House of Lords". However, in April 1653 Cromwell, disgusted with the Rump's lack of fervor, brought in a squad of musketeers and dismissed it after a fiery speech. This led to a new, more radical Parliament, known as the Barebones Parliament, named after a popular preacher Praise-God Barbon (AKA Barebones). However, moderates in this body met separately, dissolved it and turned all power over to Cromwell.*

*Not to be outdone by his father, Praise-God named his son Nicholas Unless-Jesus-Christ-Had-Died-For-Thee-Thou-Hadst-Been-Damned Barbon, who seems to have pioneered fire insurance, after the Great Fire of London in 1666.

The Protectorate (1653-8) was Cromwell's next government. It had a written constitution, the Instrument of Government, but, for all intents and purposes, it was a military dictatorship under Cromwell as Lord Protector. In addition to a Secret Service, Cromwell's secretary of state, John Thurloe started the British civil service, which carried on from ruler to the next, providing England with a new level of continuity and stability.

Cromwell's court. In an effort to look legitimate and in accordance with what he felt his position demanded, Cromwell ran a very formal court at Whitehall Palace. Even his former comrades had to bare their heads and address him as Your Highness. There were numerous concerts there, typically to entertain foreign dignitaries. Representatives from Venice and the Dutch Republic both described Cromwell's court at Whitehall as one of the most formal courts in Europe.

Life in Cromwell's England. Inside England, people felt Cromwell's heavy hand as well. His wars, standing army of 30,000 men, and navy required taxes three times higher than any which James I and Charles I had ever imposed. Churches were more locally controlled, but people were expected to live good religious lives.

Theaters, taverns, and racetracks were all closed down. People dressed in somber colors to reflect the mood of the ruling regime. Life under Cromwell seemed like Calvinist Geneva, except on a much grander scale.

Although Cromwell outlawed such things as dancing, cards, theatres, and sports, Catholics were allowed to worship in the privacy of their homes.

Surprisingly, he also invited the Jews, exiled since the 1200s, to return to England. Rather than religious tolerance, this was inspired by the somber belief that for the End of Days to occur as predicted in Revelations, the Jews had to return to their homeland. While most people figured that homeland was Palestine, Cromwell, maybe just to play it safe, thought it might be England, at least for any Jews who had lived there previously.

More recently, many modern fundamentalist Christians have supported the state of Israel for the same reason.

"To Hell or Connaught": A Brief History of Ireland

With his troops wavering, Cromwell personally led the final assault on Drogheda, which subsequently suffered a massacre at the hands of the New Model Army.

A brief history of Ireland. In 1169 the Normans invaded Ireland, gradually extending their control over the following centuries. For most of the Middle Ages Ireland was ruled as a separate kingdom under the British crown. By 1300, the area controlled by the Anglo-Normans had reached its greatest extent. However, by 1450, the Irish had regained control over much of their land. In the 1500s, the English started to regain control of parts of Ireland. In 1603 the defeat of the Irish in Ulster gave Britain complete control of Ireland.

Unfortunately, the Protestant Reformation added a new and volatile element to the struggle: religion. Now it wasn't just a struggle about land. It was a struggle about God.

In 1641, the Catholic Irish rebelled against their Protestant English masters. In England, Anti Irish-Catholic propaganda showed supposed Irish atrocities committed against English and Irish Protestants in Ireland. However, the English Civil Wars delayed English efforts to respond to the uprising and come to the aid of Irish Protestants being besieged at Drogheda.

Finally, in 1649, Cromwell landed in Ireland to quell the revolt. His bombardment and storming of Drogheda was one of the most notorious of his acts. With his troops wavering, Cromwell personally led the assault on the gates of the city. When it fell, all soldiers, priests, and a number of civilians were massacred.

"I wish that all honest hearts may give the glory of this to God, to whom indeed the praise of thy mercy belongs."--Cromwell

Cromwell hoped one massacre could intimidate the Irish into submission. It didn't.

Therefore, 1500 more were massacred when Wexford was taken.

Other towns offering resistance suffered the same fate.

When Cromwell had to leave Ireland to take care of Scotland, his policy of massacres was abandoned. However, another policy that would prove in the long run more destructive to the Irish people was now implemented: land confiscations.

Cromwell's confiscations were the result of the lack of cash to pay his troops at the end of the war. Therefore, he confiscated land and gave it to his troops in lieu of money. Any Irish unable to prove loyalty to the Commonwealth had their property confiscated. To ensure continuing control over the troublesome province of Ulster, the land was confiscated and given to small Scottish farmers. Dispossessed landowners were given poor quality land in Connaught in exchange, leading to the Irish expression "To Hell or Connaught."

By 1692 the English had seized two-thirds of Irish land for themselves. As a result, starvation and disease may have killed 50% of the Irish population by 1692. According to one traveler, "...a man might travel 20 or 30 miles and not see a living creature."

The drastic effects of Cromwell's rule on Irish land ownership between 1641 and 1703

Cromwell's religious policies outlawing Catholicism were no less disruptive. Priests were ordered out of the country in 20 days. Anyone harboring a priest could be executed, although this was not strictly enforced after the war. Magistrates could even take Irish children and ship them to England for a proper Protestant education.

The long-term results for Ireland were also devastating. The one thing the Irish could grow on the land left to them was the potato. This sustained them well until the 1840s when the Potato famine hit. Although English landlords, who controlled the best two-thirds of Ireland's land, had extra food, they exported it to England while maybe a million Irish starved to death.

Outrage over their plight would eventually lead to the Irish Revolution in 1916.

This was the source of the religious strife still afflicting Northern Ireland today.

"A contemporary song by the group, the Pogues, reflects the bitterness still found in Ireland:

*A curse upon you Oliver Cromwell
You who raped our Motherland
I hope you're rotting down in hell
For the horrors that you sent
To our misfortunate forefathers
Whom you robbed of their birthright
'To hell or Connaught' may you burn in hell tonight"*

The First Anglo-Dutch War (1651-53)

In 1651, Cromwell passed the Navigation Act, which said imports to England had to come either on English ships or ships from the countries where the goods were made. This was an obvious blow against the Dutch who profited greatly from the carrying trade. The result was the First Anglo-Dutch War. Since the Dutch up to liberation in 1648 had concentrated on trade and defeating the Spanish Army, they didn't have as powerful a navy as Britain's, and did poorly in this war. However, in the next two Anglo-Dutch wars they would more than hold their own by building large warships and adopting the English tactic of fighting in one long line to make best use of the broadsides from their cannons.

In 1653, the two countries' fleets of 120 ships each met in a bloody and indecisive battle at Scheveningen (above). Although a tactical draw, it did break the British blockade of Holland and led to peace. From Cromwell's point of view, this ensured that Johan de Witte's party remained in power to prevent the young William III of Orange, Charles II's nephew, from taking over and trying to restore his uncle to the throne of England. Ironically, it would be William who would overthrow the Stuart monarchy and seize the throne in 1688 in the Glorious Revolution.

Cromwell's Later Rule

Anti-Cromwell propaganda portraying him as the Anti-Christ

As people grew increasingly tired and resentful of Cromwell's dictatorship, resistance increased, which caused Cromwell to tighten up even more, leading to more resistance and resentment, and so on. Parliament, which still had the power to grant taxes, dragged its feet to give him those taxes, so he dismissed it in 1655. But his need for money forced him to call Parliament the next year, although he kept 100 elected members from taking their seats, so they delayed some more. However, a plot against Cromwell's life woke Parliament to his importance, and it granted him his money.

Outside of Parliament, resistance might take the form of non-cooperation or sabotage. Secretly printed pamphlets attacking Cromwell multiplied. Plots and rising by Levelers and other religious sects led to curtailing religious liberties. In opposition to Cromwell's policies, several judges resigned their posts in protest.

Although Cromwell did refuse an offer to take the crown, probably realizing its unpopularity with the army in particular, he did increase his power in other ways. He had gold coins minted showing his head crowned with a laurel wreath on the front. He also mimicked royalty by maintaining a lavish court and having himself treated as a virtual king. In 1657 he passed the Humble Petition and Advice, giving him the power to nominate a successor, much like a king would do. The next year he selected some members of Parliament to form a new Upper or Other House, which many saw as a revival of the House of Lords. That same year, reacting to further resistance, he dismissed Parliament for the third time in five years.

A British gold crown from 1658 with Cromwell's head crowned with a laurel wreath on the front. Cromwell also mimicked royalty by maintaining a lavish court and having himself treated as a virtual king.

Three years after his death and a year after the restoration of the monarchy, a mob dug up Cromwell's body and hanged it from a gallows.

96C. THE ENGLISH REVOLUTION FROM THE RESTORATION MONARCHY TO THE GLORIOUS REVOLUTION (1660-1688)

*"Here lies our lord and sovereign king
whose promise none relies on.
He never said a foolish thing
nor ever did a wise one."*

-- court jest concerning Charles II

*"That is very true, for my words are my own, and
my actions are my ministers'."-- Charles' reply*

Charles II & the Restoration Monarchy (1660-85).

The above quoted poem says a great deal about the reign of Charles II. The English people were ready to throw off Cromwell's strict Puritan rule and enjoy life again. Theaters, taverns, and racetracks opened up again. Flamboyant fashions and hairstyles became the rage. And Britain once again became "Merry Old England". Charles, the "Merry Monarch" seemed to be just what the English people needed. However, despite all this, there still remained an undercurrent of tensions in the areas of politics, money, and religion

In politics, things seemed much calmer than they had been for decades-- at least at first. King and a largely cavalier Parliament seemed reconciled. Charles was voted a sizable income. The army was paid off, and most of the crown's enemies from the civil war were granted pardons. However, many of the old tensions between king and Parliament still existed. For one thing, the Restoration not only restored the king. It also restored Parliament, which Cromwell had suppressed. In fact, it was the restored Parliament that formally summoned Charles back to England, not the king who summoned Parliament. Parliament itself was divided into two parties: the *Tories* who favored a

strong king and a Church of England largely resembling the Catholic Church, and the *Whigs* who favored a strong Parliament and more Protestant Church and ritual.

As far as money was concerned, England's wealth was rapidly growing. Cromwell's aggressive foreign policy had intensified England's commercial and naval rivalry with the Dutch, largely due to the Navigation Act, which excluded foreign, and particularly Dutch, ships from carrying English goods. This led to three short but bitterly fought naval wars with the Dutch (one under Cromwell and two under Charles II). Although the Dutch held their own, the expense and stress of their wars against England and France allowed the English to replace them as the premier naval and commercial power in Europe by 1700. Between 1670 and 1700, England's foreign trade grew by 50 per cent, and the king's customs revenues tripled. Despite this new prosperity, Charles' allowance from Parliament still could not satisfy his extravagant personal tastes and style of living. Instead of letting this lead to a clash with Parliament, as it had led to Civil War in 1642, Charles neatly sidestepped Parliament by signing the Secret Treaty of Dover with Louis XIV. This gave Charles a handsome pension in return for the promise to turn England Catholic when the time was ripe.

Concerning religion Charles II was sly enough to keep to himself his beliefs in the Divine Right of Kings and the Catholic faith. Although he did not openly profess his Catholic faith until he was on his deathbed, he did restore lands confiscated since the civil war to the Church, crown, and nobles. He also restored the power of the Church of England, re-establishing the church courts and persecuting anyone, especially Puritans, not conforming to the Church's doctrines.

Much more unsettling was the fact that Charles had many children, but none of them were legitimate. That left James, Charles' brother and an avowed Catholic, next in line for the throne. This alarmed the Puritans, who put pressure on Charles to disinherit his brother. Puritan pressure intensified with Titus Oates' "Popish plot," a preposterous rumor that the Jesuits were plotting to kill Charles and massacre all the Protestants in England. This

led to two years of anti-Catholic persecutions and hysteria, which put Charles in an awkward position, since he did not want to be exposed as a "papist" himself. Rumors of his funds from France made his position that much more delicate. In the end, the slippery Charles managed to avoid disinheriting his brother. He even ruled without Parliament the last few years of his reign, getting by on his subsidies from Louis XIV. By Charles' death in 1685, it seemed the king was as strong as ever.

James II and the Glorious Revolution (1685-88).

As strong as the new king, James II, may have appeared, there was no way he could undo the changes of the last 80 years. Charles II was a capable monarch quite adept at handling the Whigs. Unfortunately, James had nearly all the qualities to ensure getting himself dethroned, being bigoted, stubborn, and quite inept. His worst mistake was his open preference for Catholicism. He suspended laws keeping Catholics out of public office and even recruited Irish Catholics for his army. When his own bishops tried to advise him to reconsider his openly favoring Catholicism, he jailed seven of them in the Tower of London.

Even the Tories came to fear the king's religious views more than they did the Whigs' political views. Finally, they joined with the Whigs in inviting James' Protestant daughter, Mary, and her husband, William the Prince of Orange, to come from Holland and dethrone James. What followed is known as the Glorious Revolution, partly for being virtually bloodless (except for James' nosebleed), but mainly for what it accomplished. William and Mary's Dutch army landed unopposed and marched to London. James' army deserted him, and he fled to France.

Royalty and Parliament then came to an agreement whereby William could use England's resources to help stop Louis XIV's drive to dominate Europe. In return, William and Mary guaranteed Parliament's rightful place in the government and signed the Bill of Rights, precursor to our own Bill of Rights. This assured Englishmen such liberties as free speech, free elections, no imprisonment without due process of law, and no levying of taxes without Parliament's consent. In addition, the king agreed to call for new elections every three years. The king could still

formulate policy and name his officials. However, the balance of power had definitely shifted in favor of Parliament, especially since it controlled the purse strings. Money was only granted one year at a time, which meant that the king would have to call Parliament each year just to have the cash needed for his policies. This new government where even the king where was subject to the law and certain legal procedures in ruling is called *constitutional monarchy*,

In the years to come, Parliament gradually gained more power at the expense of the kings. This process gained momentum when the German prince, George of Hanover, became king in 1714. His main interests remained on the continent, and he was generally content to let his allies, the Whigs, run the government for him.

Results of the English Revolution. The struggle between kings and Parliament throughout the 1600's ended in a clear-cut victory for Parliament. While a more democratic government emerged as a result of the English Revolution, keep in mind that rather high property qualifications still kept the vast majority of Englishmen from voting.

However, the English Revolution would benefit all England in two areas: civil rights and the economy. For one thing all Englishmen did gain certain civil rights, such as free speech and the right to a fair trial by a jury of peers. Also, all Christians except gained religious freedom, except Catholics and Unitarians, who eventually, would also be tolerated. The English Revolution also opened the way for more democratic reforms over the next two centuries, until England would become a truly democratic society. The power and success of these principles would spread to the American and French Revolutions, and from France to the rest of Europe and the world.

Economically, the English revolution saw the triumph of capitalism in England. One important aspect of this was Parliament's founding of the Bank of England (1694) through which the government did much of its business. The important thing here was that the government guaranteed repayment with interest on any loans it took out. This contrasted sharply with the old

medieval method whereby kings took out personal loans, often did not bother to pay them back, and let the liability for the loans go to the grave with them. Now that government was identified more with Parliament, liability for the loans did not die with the king. Therefore, people were more willing to loan the government money, since they knew they would get it back with interest.

Since hard-nosed middle class businessmen rather than extravagant nobles with no sense of the value of money now ran the government, it would use these loans wisely by investing them in business and new industries. That, in turn would improve the economy, which not only could pay more taxes, but also invest further in the Bank of England, which could invest even more money in economic development, and so on. Therefore, England, along with the Dutch Republic, was one of the first modern states to operate at a profit rather than in chronic debt. And, as a result, England would be the birthplace of the Industrial Revolution in the 1700's, a factor that would make Europe the dominant culture on the globe by 1900.

Merry Old England Once Again

After the dour and repressive rule of Cromwell and the Puritans, England was ready for a break. They got it with Charles II, not the best king Britain had, but probably the best one the Stuart dynasty produced in that at least he knew how to keep his mouth shut & just let the British people relax a bit. Thus Restoration England (1661-88) was an age of Big Hair, flamboyant clothes, and looser morals.

Indicative of this was the series of royal mistresses, including the most scandalous of them, the actress Nell Gwynn, who referred to the king as “my Charles the Third.” The king’s scandalous personal life hurt his public image

and the ability of others, especially Louis XIV, to control him through his mistresses.

Another sign of the times was the reopening of the theaters. Restoration Theater, as it was called, drew heavily upon French influence, largely because the royal family had spent two decades in exile there. In addition to the neo-classic tragedies of Racine and Corneille, the comedies of Moliere were copied and imitated.

Other French influences included the introduction of stage machinery (for seventeenth century “special effects”) and actresses onto British stages. (The first use of French actresses in London in 1629 aroused great indignation, but paved the way for their later acceptance.)

Women were also breaking into the ranks of playwrights, notably Madame Scudéry and the Countess de la Fayette in France who wrote semi-historical romances. Following in their footsteps in England were equally successful women: Mrs. Aphra Behn, Mrs. Manly, and Mrs. Susannah Centlivre, the last of whom successfully adapted a number of French plays into English.

Restoration comedy drew heavily on the comedies of manners made popular by Moliere in France, using fairly stock characters: smooth sophisticated men about town, frail and beautiful women for them to court, dim-witted husbands and fathers for them to fool, and various minor characters, such as gossiping neighbors and clever servants, to fill out the cast. Plots were fairly predictable, often with unlikely coincidences to resolve the plot at the last minute, much as in the New Greek Comedy of Menander and copied by the Romans Plautus and Terence.

The Black Death Returns (1665)

In 1665 the last major outbreak of plague in England hit London, and “Bring out your dead” became more than a line from a Monty Python movie. Because of the large numbers of victims, they were buried in common pits.

A bad decade. The 1660s were a bad decade for Britain, starting with the Dutch victory over the British in the Four Days Battle (1664) where 8000 English sailors died, many in burning ships. After that came the Black Death (1665), the Great Fire of London (1666) and a humiliating raid by the Dutch fleet into the middle of English waters. Many people blamed these disasters on the king’s immoral behavior and suspicions that he was secretly Catholic. (He was.)

In 1665 the last major outbreak of plague in England hit London, and “Bring out your dead” became more than a line from a Monty Python movie. Because of the large numbers of victims, they were buried in common pits.

Above: a doctor’s robe. The beak was meant to act as a filter, being filled with perfumes & alleged disinfectants. The lenses were supposed to protect the eyes from the plague’s poisonous emanations.

Except for those rich enough to leave town and the plague behind, the best option was the quarantine, which involved boarding up windows and padlocking doors of any house where there was a sick person. Guards outside kept the whole family confined indoors until 28 days after the last signs of the plague had passed, at which time all the clothes and bedding of the victims would be burned.

Death and nursery rhymes. It is good to remember that, while European Civilization was progressing, life went on much as it had for centuries and people still had to deal with the same problems they dealt with in the Middle Ages: Plague, fire, and famine. Nothing could better illustrate the significance of plague than how it has come down to us in a famous nursery rhyme:

"Ring a ring-a-rosies
A pocketful of posies
Tishoo Tishoo
We all fall down."*

*Rosies= rash accompanying plague

An alternative version of "Ashes, ashes" could refer either to the ashen color of buboes or ashes from burning bedding & clothes.

The fact that so many nursery rhymes had to do with grim themes such as plague, Bloody Mary, and Vikings tearing down bridges shows how there was a much fuzzier barrier between the worlds of adults and children then, with a corresponding lack of understanding of childhood as a distinct stage of life.

When it finally subsided in December 1666, the plague had killed an estimated 70,000 people in London. But another disaster lurked just around the corner: fire.

Farewell Tour. This was, in a sense, the farewell tour of the Black Death, the last major outbreak of Bubonic Plague in Europe occurring in Naples in 1756. There are a number of theories about why it subsided, including the replacement of thatched roofs (where the Black Rat liked to burrow) with tiled roofs and the supplanting of the Asian Black Rat with the European Brown Rat, which avoided human more than its Asian

cousin did. While none of these theories is mutually exclusive, very likely, a less deadly strain of plague had evolved that didn't kill its host and force it to find a new host. Meanwhile, the more deadly strain killed off all its hosts and reached a dead end, leaving the less deadly strain, which is still with us.

Food for thought: Like microbes, rats, and fleas, humans are a parasite on their host (planet Earth), only becoming a disease if we are harmful or deadly to our host.

The Great Fire of London (Sept. 1-4, 1666)

London in September 1666 had the ingredients for the perfect (fire)storm. For one thing, it began close to warehouses full of combustible materials (brandy, tar, oil, butter, wine). Secondly, that summer had been exceptionally dry. And third, the fire started on the east side of town with a strong easterly that blew relentlessly for four days, thus spreading the fire across the city.

It started when the king's baker was woken by smoke. Finding their escape blocked, he and his wife climbed to the roof and leapt to the next one. Unfortunately, his wife missed and fell to her death in the flames below, the first of only six fatalities from the Great Fire of London. The lord mayor, hung over from the previous night's parties, was slow to realize the seriousness of the fire and organize bucket brigades to fight it. By the time he did, the fire was too intense and widespread to combat. Soon one-third of the buildings on London Bridge were in flames. Down below in the river refugees floated to safety downstream with whatever goods they could salvage.

Since the Lord mayor was so ineffective, King Charles took charge, ordering men to tear down

buildings in the fire's path, even blowing them up with gunpowder. However, the fire was spreading too quickly even for that.

Everywhere there was the sound of women and children shrieking, roaring flames, people pleading with officials not to destroy their homes, and the thunder of buildings crashing to the ground. In the midst of it all was the king who took part in bucket brigades and passed money out to fire fighters, something which revived his reputation somewhat. Adding to the panic were rumors the Dutch had set the fire and were sailing up the Thames to attack. (They would do that the next year.)

Samuel Pepys, an eyewitness to the fire, kept a diary which is one of our best sources for the fire: *"O the miserable and calamitous spectacle, such as happily the whole world had not seene the like since the foundation of it, nor to be out don, 'til the universal Conflagration of it, all the skie were of a fiery aspect, like the top of a burning Oven, and the light seene above 40 miles round about for many nights. God grant mine eyes may never behold the like, who now saw above ten thousand houses all in one flame, the noise and crackling and thunder of the impetuous flames, shreeking of Women and children, the hurry of people, the fall of towers, houses and churches was like an hideous storme.... Thus I left it this afternoone burning, a resemblance of Sodome, or the last day... London was, but is no more!"*

When it finally had run its course, the fire had destroyed 5/6 of London, 13,200 houses, and 87 of 97 churches. Some 200,000 people were left homeless and subsisting in fields outside London.

Amazingly, only 6 people died.

It had started in Pudding Lane and stopped at Pie Corner.

Out of this destruction arose a new London, including the new St. Paul's Cathedral built by Christopher Wren, using the classical elements of the dome and columns in the baroque style of the 1600s. Wren's original design was turned down because it looked too much like churches in Catholic Rome. That was fine with the

secretly Catholic king Charles, but not with the Puritans or even the Anglican cavalier supporters of the monarchy. Wren also had a grand design for rebuilding London as a much cleaner and more organized city. However, officials passed it up, mainly because of its expense.

A Thriving Home and Colonial Economy. During Charles II's reign, one could see the beginning of British prosperity that would vault it into the forefront of the industrial revolution a century later. By 1700, half of England's land had been enclosed to take advantage of the new more productive agricultural techniques being developed. While on the continent, low agricultural prices led to limited production, in Britain both the government and private investors were raising production to make the country agriculturally self-sufficient.

The introduction of the Dutch loom in the 1690s meant a weaver could make 12 pieces of ribbon over 400 meters long in two days, a great boost in productivity. The Immigration of Huguenots expert in the production of textiles, book printing, papermaking etc. after 1685 helped transform the manufacture of watches, cutlery, fine textiles, and glass into industries catering to a larger clientele. The de-regulation of the textile industry's control of such things as apprenticeship, work conditions and wages also help create a flourishing free market.

Better agriculture and more efficient production of goods combined to create more of a "consumer economy" where English yeomen (prosperous farmers) and shopkeepers could buy colorful clothes, coffee, sugar and tobacco.

England was also importing goods from the colonies and re-exporting them for huge profits. Between 1630 and 1700 tobacco exports from

Maryland and Virginia rose by a factor of twenty times. Sugar imports, which were negligible in 1630, reached 4-million pounds between 1699 and 1701. At the same time two-thirds of the tobacco and Indian Calico and one-third of the sugar being imported was re-exported for profit. In the last four decades of the 1600s, the re-export of colonial goods to Europe jumped by a factor of four times.

From 1580 to 1700 the number of brewers skyrocketed from 26 to 180. In the 1700s distilled liquors such as gin would see even more dramatic growth with disturbing results.

"Rock-a-Bye-Baby" and the Glorious Revolution

The "Warming Pan Baby". People were willing to wait for James II (above) to die, since he had no heir to the throne-- until Queen Mary Beatrice announced she was pregnant. Many liked to claim the pregnancy was a hoax, with a baby being sneaked into to the birthing room in a warming pan, which usually held hot coals and was placed under a bed to keep it warm on cold winter nights. Hopefully it wasn't used for both functions simultaneously.

Rock-a-bye Baby was another nursery rhyme that came out this period's history. The baby in the song is the aforementioned "warming pan baby" of James II. The breeze refers to the wind that blew William and Mary's fleet over from Holland. The baby falling represents the fall of the Stuart monarchy.

The Jacobites (supporters of Stuart claims to the British throne) continued to press those claims into the 18th century. Their last good hope for restoring the Stuarts lay with Bonnie Prince Charlie of Scotland, who was finally defeated at the Battle of Culloden in 1746.

96.D THE COMPARATIVE GEOGRAPHIES & HISTORIES OF ENGLAND AND FRANCE IN THE 1600s

While just a few miles of the English Channel separate France and England, their respective histories, while similar in some ways have diverged somewhat in others. Once again, one of the main factors in the equation has been geography, the fact that England is an island and relatively safe from invasion, while France is on the continent and in closer contact with its neighbors, sometimes in hostile ways.

Another factor affecting England has been a longer democratic, or more properly quasi-democratic, tradition compared to that of France, going back at least to the Magna Charta in 1215, although that was drawing upon an earlier charter signed by Henry I around 1100, which itself drew upon older traditions of Saxon liberties. Together, England's protected position, but still very close to the continent, and its quasi-democratic roots blessed it with few invasions and more trade. Therefore it had less need for a strong army, giving it a stronger and richer middle class and a less powerful and distinct nobility than in France. For example, lower nobles and the upper middle class sat together in the House of Commons as a group known collectively as the gentry. While titles of nobility could not be bought in England, neither could they be lost, as in France, for the stigma of working to support oneself like the a commoner.

By 1700, England had worked out a constitutional monarchy that was more democratic, giving all freemen certain civil rights, although withholding the vote from all but about 5% of the men. Two major pillars supported this new order. One was Protestantism, which sees all believers as (at least spiritually) equal in God's eyes. In the early 1600s when one could not separate religion and politics, spiritual equality led the way to political and social equality. The other pillar was free trade capitalism, versus the quasi-socialistic system of medieval guilds, royal monopolies, and mercantilism. Running this was the same Protestant middle class gentry that ran Parliament and claimed that God values all jobs equally. In the 1700s the combined dynamics of middle class capitalism and democracy would vault England into global leadership in terms of finance, naval and colonial power, and eventually industrialization.

France's geography and history took it down a somewhat different path, at least until the 1800s. Its position on the continent presented more threats of

invasion, as well as opportunities for conquest. Either way, it had a greater need for an army, which is expensive and disruptive to trade when it is actually used in wars. Therefore, the middle class had less clout and status in France than its counterpart in England, as witnessed by the more prominent role played by Parliament in English history than that played by its French counterpart, the Estates General. Also, there was no blending of the upper middle class and lower nobles corresponding to the gentry in England.

As a result, France experienced an absolute monarchy that was supported by its religious and economic systems. One was state enforced Catholicism with the doctrine of Divine Right of Kings, which supported the principle of absolute monarchy. The economic counterpart to absolute monarchy was mercantilism, which did recognize the importance of nourishing a strong national economy, but did it in an overbearing absolutist manner that stifled initiative and may have done as much harm as good.

However, instead of continuing on diverging paths, France would follow with its own democratic revolution and the triumph of free trade capitalism for two major reasons. One was political and economic competition from Britain that France had to adapt to in order to survive. The other was a common cultural and historical heritage going back to ancient Rome, which made France and England much more alike than either of them might want to admit.

THE BIRTH OF MODERN SCIENCE

Western science, like so many other aspects of Western Civilization, was born with the ancient Greeks. They were the first to explain the world in terms of natural laws rather than myths about gods and heroes. They also passed on the idea of the value of math and experiment in science, although they usually thought only in terms of one to the exclusion of the other. It is easy for us to be critical of their early scientific theories, but we must remember several things about their world. First, by that time, the human race had learned to exploit the environment for survival (e.g., agriculture, woven cloth, metallurgy, etc.), but knew little about the physical laws that rule nature and the universe. Also, there were no telescopes, microscopes, or other instruments to aid the naked eye in its observations and measurements. Everything they learned about the natural world had to be done with the unaided senses and whatever rational deductions they could make based on them.

Knowing the limitations the Greeks operated under helps us appreciate the scientific view of the world they evolved and handed down to posterity. The Greeks realized the limitations to their observations, and many of them argued that relying on one's senses was a faulty way to unravel the mysteries of the universe. The philosopher, Plato, compared our perception of reality to that of a man chained to the wall of a cave who only sees shadows from the outside world cast against the opposite wall.

However, other Greek philosophers argued that use of the senses for observation, as faulty as it may be, was still worthwhile. One of these Greeks, and by far the most influential figure in Western science until the 1600's, was the philosopher, Aristotle, who created a body of scientific theory that towered like a colossus over Western Civilization for some 2000 years. Given the limitations under which the Greeks were working compared to now, Aristotle's theories made sense when taken in a logical order.

Three basic observations laid the foundations for Aristotle's view of the universe and laws of motion: First of all, there was the theory of the

elements. The Greeks came up with several theories on the elements, including Democritus' atomic theory, the idea that all matter is composed of tiny indivisible particles called atoms (from the Greek *atomon* = indivisible). Other Greeks observed three basic states of matter: solid, liquid, and gas. As a result, they came up with four basic elements to correspond to the states of matter: earth (solid), water (liquid), air (gas), plus fire, which the Greeks saw as an element. Of course, since few objects are made of just one element, it was logical to assume they were compounds of two or more of the terrestrial elements. The Greeks spent a good deal of time figuring out what elements different objects contained by observing the qualities they exhibited. For example, wood is composed of earth (because it is solid), fire (because it burns), and air (because the ash left behind floats on top of water). Second, there was the observation that the stars, sun, planets, and moon *seem* to orbit the earth in perfect circles. Finally, all dropped objects seem to fall toward the center of the earth. These led to several important conclusions.

For one thing, the theory of four elements plus the perfect circular orbits of the stars and planets gave rise to the idea that the celestial bodies were made of a perfect element, *ether*. Ether was weightless or very light so the stars and planets could easily orbit the earth every day. It must also be perfect, incorruptible, and unrelated to the earthly elements since its motions are always in perfect circles, a motion rarely seen on earth.

Second, the motion of dropped objects toward the center of the earth (no matter where on earth they are dropped) and the apparent orbits of the heavenly bodies around the earth led to the *geocentric theory*, the idea that the earth is the center of the universe. Aristotle and most educated Greeks assumed the earth was round since one can see ships disappear over the horizon, the earth casts a round shadow on the moon during lunar eclipses, and the positions of the stars change as we move north or south.

Finally, there was Aristotle's law of motion. Aristotle saw that heavier objects (made of earth and water) have a tendency to fall or sink toward the center of the earth, while lighter objects (made of air and fire) rise or float. He called these

tendencies of the elements to rise or fall *natural motions* and said that all elements have an inclination to rise or fall to their natural resting places in relation to one another. Aristotle called all other terrestrial motions *forced* or *violent motions* since they needed an outside force in constant contact with the object in order to take place. Thus the theory of four terrestrial (earthly) elements and the falling of those elements toward the center of the earth led to a law of motion which said that for forced motion everything must stay in contact with a prime mover to keep moving and could only be stopped by some other intervening object or force.

Toward a new universe: the downfall of Aristotle (1543-1687). There were several factors that worked both to overthrow Aristotle's system and to preserve it. First of all, Aristotle's theories relied very little on experiment, which left them vulnerable to anyone who chose to perform such experiments. However, attacking one part of Aristotle's system involved attacking the whole thing, which made it a daunting task for even the greatest thinkers of the day. Secondly, the Church had grafted Aristotle's theories onto its theology, thus making any attack on Aristotle an attack on the tradition and the Church itself.

Finally, there were the Renaissance scholars who were uncovering other Greek authors who contradicted Aristotle. This was unsettling, since these scholars had a reverence for all ancient knowledge as being nearly infallible. However, finding contradicting authorities forced the Renaissance scholars to try to figure out which ones were right. When their findings showed that neither theory was right, they had to think for themselves and find a new theory that worked. This encouraged skepticism, freethinking, and experimentation, all of which are essential parts of modern science.

Pattern of development. The combination of these factors generated a cycle that undermined Aristotle, but also slowed down the creation of a new set of theories. New observations would be made that seemed to contradict Aristotle's theories. This would lead to new explanations, but always framed in the context of the old beliefs, thus patching up the Aristotelian system. However, more observations would take place, leading to

more patching of the old system, and so on. The first person who started this slow process of dismantling Aristotle's cosmology was Copernicus. His findings would reinforce the process of finding new explanations, which would lead to the work of Kepler and Galileo. The work of these three men would lead to many new questions and theories about the universe until Isaac Newton would take the new data and synthesize it into a new set of theories that more accurately explained the universe.

The University of Padua was where many pioneers of the Scientific Revolution, including Copernicus, worked. Being under Venice, which had bad relations with the Church since it traded with Muslims, it had an unusual degree of academic freedom & was a major center for new scientific findings in the Renaissance.

Nicolaus Copernicus was a Polish scholar working at the University of Padua in northern Italy. The problem he wrestled with was the paths of planetary orbits. Through the centuries close observations had shown that the heavens do not always appear to move in perfect, uninterrupted circles. Rather, they sometimes seem to move backwards in what are known as retrogradations. (This phenomenon occurs when the Earth passes another planet in its orbit, thus making it appear to go backwards.) In order to account for these irregularities, astronomers did not do away with Aristotle's theory of perfectly circular orbits around the earth. Instead, they expanded upon it, adding smaller circular orbits (epicycles) that spun off the main orbits. These more or less accounted for the retrogradations seen in orbits. Each time a new irregularity was observed, a new epicycle was added. By the 1500's, the model of the universe had some 80 epicycles attached to ten crystalline spheres (one for the moon, sun, each of the five known planets, the totality of the stars, a sphere to move the other spheres, and heaven). The second century Greek astronomer, Ptolemy was the main

authority who put order to and passed this cumbersome system of epicycles to posterity.

Copernicus' solution was basically geometric. By placing the sun at the center of the universe and having the earth orbit it, he reduced the unwieldy number of epicycles from 80 to 34. His book, *Concerning the Revolutions of the Celestial Worlds*, published in 1543, laid the foundations for a revolution in how Europeans would view the world and its place in the universe. However, Copernicus' intention was not to create a radically new theory, but to get back to even older ideas by such Greeks as Plato and Pythagoras who believed in a heliocentric (sun centered) universe. Once again, ancient authorities were set against one another, leaving it for others to develop their own theories.

It took some 150 years after Copernicus' death in 1543 to achieve a new model of the universe that worked. The first step was compiling more data that tarnished the perfection of the Ptolemaic universe and forced men to re-evaluate their beliefs.

Meanwhile, two celestial phenomena added further doubts about the Aristotelian system. First, a bright new star (probably a supernova explosion) suddenly appeared in 1572. Within a year, it was gone from the sky, leaving in its wake doubts about the changeless perfection of the stars. Five years later, a new comet cut across the skies and through the crystalline spheres that were supposed to hold the stars and planets in their orbits. Of course, the question was raised: did such perfect spheres even exist, and, if they did, how could a comet cross through them?

Johannes Kepler. At this time, a Danish astronomer, Tycho Brahe, using only the naked eye, tracked the entire orbits of various stars and planets. Previously, astronomers would only track part of an orbit at a time and assume that orbit was in a perfect circle. Brahe kept extensive records of his observations, but did not really know what to do with them. That task was left to his protégé, Johannes Kepler.

Kepler was a brilliant mathematician who had a mystical vision of the mathematical perfection of the universe that owed a great deal to the ancient

Greek mathematician Pythagoras. Despite these preoccupations, Kepler was open minded enough to realize that Brahe's data showed the planetary orbits were not circular. Finally, his calculations showed that those orbits were elliptical. As important as Kepler's conclusion was his method of arriving at it. He was the first to successfully use math to define the workings of the cosmos. Although such a conclusion as elliptical orbits inevitably met with fierce opposition, the combination of Brahe's observations and Kepler's math helped break the perfection of the Aristotelian universe. However, it was the work of an Italian astronomer armed with a new invention, the telescope, which would further shatter the old theory and lead the way to a new one.

Galileo Galilei (1564-1642). In the year 1608, several Flemish gentlemen arrived in Venice carrying a startling new invention: the telescope. Upon hearing of this, Galileo, who was then working in Venice, quickly figured out its principles and built one himself, increasing its magnification from three times to ten. He got the Venetian senate excited about the telescope as an early warning device that could spot enemy ships at ten times the distance as was previously possible. However, Galileo's curiosity was a bit more far ranging than spotting enemy ships, and eventually he turned his gaze toward the skies. That was when trouble began.

The impact of that first telescope can better be appreciated by imagining how our views of the universe might change if our technology increased our view of the universe by a factor of ten times. Galileo's findings were probably more disturbing. He saw the sun's perfection marred by sunspots and the moon's perfection marred by craters. He also saw four moons orbiting Jupiter. In his book, *The Starry Messenger* (1611), he reported these disturbing findings and spread the news across Europe. Most people could not understand Kepler's math, but anyone with access to a telescope could see for himself the moon's craters and Jupiter's moons.

The Church, trying to preserve the Aristotelian and Ptolemaic view of the universe, clamped down on Galileo and his book, making him promise not to *preach* his views. However, in 1632, Galileo published a new book, *Dialogue on the Great*

World Systems, which technically did not preach the Copernican theory (which Galileo believed in), but presented both views "equally" in a dialogue where the advocate of the Church and Aristotelian view was named Simplicius (Simpleton). He was quickly faced with the Inquisition and the threat of torture. Being an old man of 70, he recanted his views. However, it was too late. Word was out, and the heliocentric heresy was gaining new followers daily.

Galileo's importance to the history of science was immense, adding two critical elements that had largely been ignored. One was his tireless experimentation, observation, and careful measurements concerning astronomy and the laws of motion. This was especially remarkable in light of how little of this anyone else was doing up to that time. The other element was his use of math and the belief that we can understand nature through it. Either of these alone would have been a remarkable contribution to the history of science. Using both of them together and making them integral parts of the scientific method was an epic achievement.

One needs to understand the new problems that the discoveries of the 1500's and early 1600's presented for seventeenth century scientists. Galileo's work had done more to destroy the Aristotelian system than create a new working one. As a result, there was great confusion among scholars as to what the structure of the universe really was. There were three major problems confronting them. One problem bothering seventeenth century scientists concerned the nature of motion. Aristotle's law of inertia said a moving object had to be in constant contact with the moving force. This raised such questions as how could an arrow keep flying once removed from the force driving it. This was explained by saying the air being displaced by the arrow went around behind it and pushed it along. This seemed unlikely, since the same air driving the arrow also would also be slowing it down.

Renaissance scholars, bothered by this concept of a prime mover, came up with the new theory of Impetus. According to this, moving objects were carried forward by some vague force within the object or imparted to it like the heat in a red-hot piece of iron. The theory of impetus allowed

people to discuss motion after contact with a mover was broken. There was just one problem with this theory: it was wrong. Nevertheless, it was important, because it challenged Aristotle's authority and freed scientists to work on other problems until a better theory of motion came along. The great French mathematician, Descartes, finally came up with the modern theory of inertia, which said a moving object will keep moving in a straight line until something interferes to stop it or slow it down.

The second problem bothering philosophers was what kept objects from flying out of their orbits and into space. Descartes, like Aristotle, did not believe in the existence of vacuums, since they would create no resistance to moving objects, thus allowing them to accelerate to infinite speed, which, of course, is both impossible and absurd. Space, according to Descartes, was filled with ether and cosmic whirlpools that kept the planets in orbit. Not everyone discounted the existence of vacuums, especially since the experiments of Galileo's student, Toricelli, with barometric pressure proved that vacuums can and do exist. Once again this raised the problem of what keeps the planets and stars in orbit if ether did not

The Englishman, William Gilbert offered a solution in 1600, suggesting that magnetism was the answer. He saw the earth as a giant magnet, keeping both terrestrial and celestial objects from flying off into space. Although his theory was basically wrong, it did open people's minds to the idea of objects exerting a pull on one another. As a result, in 1643, the Frenchman, Roberval, suggested a theory of universal gravitation, the tendency of all matter to have an attraction for all other matter. However, he did not have the math to prove the theory.

Even if Roberval's theory of gravity were right, it raised a third problem: what keeps the moon and other celestial bodies from falling to earth? For Roberval, it was the resistance of ether in space. In 1665, Alphonse Borelli suggested centrifugal force. A mathematician named Huygens figured out the formula for centrifugal force, but he also believed in circular motion. And there was still the problem of what kept the sun, moon, planets, and stars in their orbits. That was where Isaac Newton came in.

The story of Newton being hit on the head by an apple may very well be true. However, the significance of this popular tale is usually lost. People had seen apples fall out of trees for thousands of years, but Newton realized, in a way no one else had realized, that the same force pulling apples to earth was keeping the moon in its orbit. Of course, Roberval had suggested this before, but Newton proved it mathematically. In order to do this, he had to invent a whole new branch of math, calculus, for figuring out rates of motion and change. The genius of Newton in physics, as well as William Harvey in medicine and Mendeleev in chemistry, was not so much in his new discoveries, as in his ability to take the isolated bits and pieces of the puzzle collected by his predecessors and fit them together. In retrospect, his synthesis seems so simple, but it took tremendous imagination and creativity to break the bonds of the old way of thinking and see a radically different picture.

The implications of Newton's theory of gravity can easily escape us, since we now take it for granted that physical laws apply the same throughout the universe. To the mentality of the 1600's, which saw a clear distinction between the laws governing the terrestrial and celestial elements, it was a staggering revelation. His three laws of motion were simple, could be applied everywhere, and could be used with calculus to solve any problems of motion that came up.

The universe that emerged was radically different from that of Aristotle. Thanks to Newton, it was within our grasp to understand, predict, and increasingly manipulate the laws of the universe in ways no one had been able to do before. Newton's work also completed the fusion of math promoted by Renaissance humanists, Aristotelian logic pushed by medieval university professors, and experiment to test a hypothesis pioneered by such men as Leonardo da Vinci and Galileo into what we call the scientific method. This fusion had gradually been taking place since the Renaissance, but the invention of calculus made math a much more dynamic tool in predicting and manipulating the laws of nature.

The printing of Newton's book, *Principia Mathematica*, in 1687 is often seen as the start of

the Enlightenment (1687-1789). It was a significant turning point in history, for, armed with the tools of Newton's laws and calculus, scientists had an unprecedented faith in their ability to ***understand, predict, and manipulate the laws of nature*** for their own purposes. This sense of power popularized science for other intellectuals and rulers in Europe, turning it into virtual religion for some in the Enlightenment. Even the geometrically trimmed shrubbery of Versailles offers testimony to that faith in our power over nature. Not until the last century has that faith been seriously undermined or put into a more realistic perspective.

Copernicus' Heliocentric Theory

The University of Padua was where Copernicus and many other pioneers of the Scientific Revolution worked. Being under Venice, which had bad relations with the Church since it traded with Muslims, it had an unusual degree of academic freedom and was a major center for new scientific findings in the Renaissance.

While working at Padua, Copernicus formed his heliocentric theory as early as 1512, thirty years before he published it, probably because he either wanted to make sure of his theory or he feared backlash from the Church. Supposedly, he was presented with a copy of the first edition of his book, *Concerning the Revolutions of the Celestial Worlds*, while on his deathbed in 1543.

In the spirit of the Renaissance, Copernicus wasn't trying to develop a new theory, but just draw upon other Greek philosophers' ideas, in particular, those of Plato and Pythagoras who saw a central fire as the center of the universe.

One implication of this theory was that, with the sun at the center, the earth must turn on its

axis, which was a lot simpler than making everything orbit the earth. A major objection to this was that, since the stars and other celestial objects were supposedly weightless, it made more sense to move them instead of the earth where all the weight of the universe was concentrated. One implication of this was that the universe must extend much further beyond the solar system than previously thought, because the stars seem more fixed (or move more slowly) than the planets, and so must lie at a greater distance from earth.

Copernicus' theory raised two other questions. First, what is the real center of the universe when earth still has all the weight of the universe? Copernicus, maybe to satisfy the Church, said it was the center of the earth's orbit (which would be the sun, but still be determined by the earth.

Secondly, if the earth rotates from west to east, why don't all winds blow east to west? According to Copernicus, since the air in the winds is a terrestrial element, the winds move in sympathy with the earth's rotation, which is basically true.

Apparently, the book was not that controversial since Copernicus was well connected in the Church. Also, he presented his theory as a mere mathematical exercise, not a real world model.

Tycho Brahe

Tycho Brahe was a Danish astronomer and flamboyant character who once got into a duel with another mathematician over a mathematical formula. Since neither could prove the other wrong, they decided to settle the matter with a duel in which the front part of Tycho's nose got chopped off. Therefore, he had a new one made of brass, carrying glue with him to reattach it when necessary. Tycho also had a pet moose or elk that he used for

entertaining guests. Unfortunately, one night it got drunk on some beer, fell down the stairs, and died.

In addition, Tycho's right eye was larger than his left from squinting while making observations through his armillary sphere, a celestial globe used to plot the motion of the stars around the Earth. It was the prime instrument of all astronomers in determining celestial positions until the invention of the European telescope in the 1600s. As a reward for saving Frederick II of Denmark from drowning, he was awarded with his own island where he could build an observatory with oversized armillary spheres for more accurate observations. His great equatorial armillary, built in 1585, was 3 meters in diameter with an estimated accuracy of 38.6 seconds of arc.

Most astronomers agreed that the supernova of 1572 took place inside the moon's orbit, and thus was made of changeable terrestrial materials. However, based on his own observations that showed no daily change against the background of other fixed stars, Tycho claimed that the supernova existed beyond the moon's orbit. This would put it in unchangeable ethereal space, which would be impossible according to current theories of the cosmos. Using similar measurements, he also showed that comets must exist beyond the terrestrial sphere in "unchanging" ethereal space. This was the first major challenge to Aristotle's theory of immutable space.

In addition to his observations, Brahe created a modified geocentric system with the planets orbiting the sun while it orbited earth. His model was geometrically identical to that of Copernicus. All that changed was what was moving and what was fixed-- the sun or the earth. In the Tychonic model of the universe, the Moon and Sun circled the Earth, while

Mercury, Venus, Mars, Jupiter, and Saturn traveled around the Sun. Around all of these was a sphere of fixed stars.

The legend surrounding Brahe's death was that he was at a party and, out of politeness to his host failed to get up to relieve his bladder. By the time he did try to go, his bladder was blocked from waiting too long. An infection developed and he died eleven days later. When his body was exhumed in 1996, analysis of his hair follicles showed he most likely died from mercury poisoning, a common enough malady back when people thought mercury had medicinal qualities. Ivan IV of Russia probably died from the same thing.

Tycho wrote his own epitaph: "He lived like a sage and died like a fool"

Johannes Kepler (1571-1630)

Kepler's music of the spheres. Kepler, who barely got his mother acquitted of witchcraft charges, was obsessed with the mystical qualities of numbers. In addition to first supporting his family by making astrological charts, he also tried to correlate the relative

distances of the planets from each other by fitting different regular geometric solids inside one another. He also believed in the Pythagorean idea of the "music of the spheres" and proposed that the eccentricities (degree of flattening) of the planetary orbits were determined by the tunes they hummed as they made their way through the heavens. Amazingly, his figures corresponded closely to Tycho Brahe's measurements.

*In the Tychonic model of the universe, the Moon & Sun (blue orbits) circle the Earth, while Mercury, Venus, Mars, Jupiter, & Saturn (orange orbits) revolve around the Sun. Around all is a sphere of fixed stars. Tycho's model is geometrically identical to that of Copernicus. All that is changed is what is moving & what is fixed-- the sun or the earth.***

For the figures below, 1.000 is taken as the mean distance of the earth to the sun.

Kepler's Harmony

Brahe's measurements

| Planet | Aphelion distance | Perihelion distance | Aphelion distance | Perihelion distance |
|---------|-------------------|---------------------|-------------------|---------------------|
| Mercury | 0.476 | 0.308 | 0.470 | 0.307 |
| Venus | 0.726 | 0.716 | 0.729 | 0.719 |
| Earth | 1.017 | 0.983 | 1.018 | 0.982 |
| Mars | 1.661 | 1.384 | 1.665 | 1.382 |
| Jupiter | 5.464 | 4.948 | 5.451 | 4.949 |
| Saturn | 10.118 | 8.994 | 10.052 | 8.968 |

Kepler's laws. Kepler's first and best-known law is that a planetary orbit is defined by an ellipse where one of the foci is inside the sun. Most

planets' orbits are almost circular, the exceptions being Mercury and Pluto whose orbits are sufficiently flattened as to be seen as ellipses upon observation.

Kepler's second law states that a line joining the sun to a planet sweeps out equal areas in equal times. However, since orbits are elliptical, not circular, the distance (and length of the line) between a planet and the sun varies. Therefore, if an equal area is swept out when the planet is closer to the sun, the planet must be moving faster during that span of time than it was when

it was farther from the sun. A century later, Newton would show that the gravitational pull of the sun accelerates a planet's speed as it is being pulled toward the sun and slows the planet's

speed as it moves away, until it reaches its furthest point and starts pulling it back.

Kepler's third law states that the square of the time of an orbital period is proportional to the cube of the length of the distance of the planet from the sun at the furthest point of the ellipse. If we use the distance from the earth to the sun (one astronomical unit or A.U.) as the unit by which we measure other planets' distance to the sun, we get the following figures:

| Planet | Distance in A.U. | R^3 | Period in years | P^2 | P^2/R^3 |
|---------|------------------|-------|-----------------|-------|-----------|
| Mercury | 0.387 | .0580 | .241 | .0581 | 1 |
| Venus | 0.723 | .378 | .615 | .378 | 1 |
| Earth | 1.00 | 1.00 | 1.00 | 1.00 | 1 |
| Mars | 1.524 | 3.54 | 1.881 | 3.538 | 1 |

Galileo Galilei (1564-1642)

Galileo originally wanted to be a monk, but his father pressured him to study medicine. After giving that up, he pursued his real passion, math, setting himself up as a private tutor and later getting a public appointment in Florence. His fame rapidly spread, and he was even invited to give a lecture on the size and location of Hell. After his father's death in 1591, he got an appointment at the University of Padua. Much of Galileo's work had to do with motion. His work on pendulums influenced the Dutch scientist, Christian Huygens, whose clock helped lead to the later development of the chronometer.

Some of Galileo's most famous experiments had to do with the velocity of falling objects. According to Aristotle, if one dropped two objects, the heavier object would fall faster in proportion to its weight. Amazingly, in the 1800

years since Aristotle's time no one had bothered to test this theory until Galileo took it on and disproved it. He did it by rolling balls of different weight down various inclined ramps, timing their speed and acceleration with a series of bells that rang as the balls passed them. Contrary to popular belief, Galileo did not actually drop objects from the Leaning Tower of Pisa.

Theories on sight

Most Greeks, such as Euclid and Plato believed that light was something that emanated from

the eyes to the object seen. Democritus and the atomists claimed light went from the object to the eye. Galen discounted this with the common sense argument that it's absurd to think that the light encompassing a mountain could fit in your eye or that one object viewed by thousands of people could generate enough light for everyone to see. (Many children and even college students still conceive of light in this fashion.)

In the 11th century, the Arabs had largely debunked this idea about sight, using the refraction of light to show that the light goes from the object to the eye. The image to the left is a study of eyes from Ibn al-Haytham's *Optics* showing the principal tunics, humours and the optic nerves connecting the eyeballs to the brain.

Invisible worlds above. No one knows for sure how magnifying an image with a concave lens was discovered. One theory is that a medieval glassmaker looked through some accidentally warped glass and got the idea. Since he was most likely an illiterate artisan, he probably didn't write about it. However by the 1300s eye glasses were in common use among the rich and were a sign of status and literacy as seen in Raphael's portrait of Pope Leo X.

Crystal reading stones were seen as superior to glass. In Venice in the 1300s, there was a law against eyeglass makers telling customers they were selling them crystal when it was only glass.

However, the Church viewed lenses somewhat suspiciously, since, by magnifying images they distorted the true image of God's creation. Besides that, theologians pointed out that God's first creation was light. Thus treating light as a mere physical phenomenon was enquiring into the physics of transubstantiation. This wasn't a major problem until Galileo pointed his telescope toward the stars.

The first telescope is attributed to a Dutch lens maker, Hans Lippershey. Supposedly, it was an accidental discovery by children playing with Lippershey's lenses and inadvertently viewing

through one convex lens lined up with a concave lens to produce the magnifying effect.

Galileo soon had made his own telescope with a magnification of 10X (later 32), even grinding his own lenses. Getting people just to look through his telescope was often hard because of the common belief that it distorted the true image and even created mirages. However, the Venetian Senate bought one of Galileo's telescopes as an early warning system against attack. Venetian merchants wanted to use it to get first shot at buying incoming cargoes.

The impact of that first telescope can better be appreciated by imagining how our views of the universe might change if our technology increased our view of the universe by a factor of ten times. Galileo's findings were probably more disturbing. He saw the moon's craters, the sun's perfection marred by sunspots, and four moons orbiting Jupiter. In his book, *The Starry Messenger* (1611), he described and sketched (below) these disturbing findings and spread the news across Europe. Most people may not have been able to understand Kepler's math, but anyone with access to a telescope could see for himself the moon's craters and Jupiter's moons.

The phases of Venus were a convincing demonstration of the heliocentric solar system, showing how the phases of Venus result from its position in the solar system between earth and the sun. Mercury also exhibits phases but it's much harder to observe than Venus. By contrast, the Ptolemaic system could explain only some of the phases exhibited by Venus.

The Church, trying to preserve the Aristotelian and Ptolemaic view of the universe, clamped down on Galileo and his book, making him promise not to *preach* his views. However, in

1632, Galileo published a new book, *Dialogue on the Great World Systems*, which technically did not preach the Copernican theory (which Galileo believed in), but presented both views "equally" in a dialogue where the advocate of the Church and Aristotelian view was named Simplicius (Simpleton). He was quickly faced with the Inquisition the threat of torture. Being an old man of 70, he recanted his views. However, it was too late. Word was out, and the heliocentric heresy was gaining new followers daily.

Galileo's trial largely centered on whether the ban of 1616 prohibited him from preaching Copernicus' theories (as he claimed, even producing a signed Church certificate to that effect) or from discussing it at all (as the Church claimed). In the end, he was found guilty of "vehement suspicion of heresy", his *Dialogue* was added to the *Index of Prohibited Books*, and he was put under house arrest for life.

Some of Galileo's most important work took place in the last ten years of his life while he was under house arrest. In 1638, he published *Discourses on the Two New Sciences*, having sneaked out the manuscript despite the Church's ban on him publishing anything else. This new book contained much of his work on laws of motion, including a mathematical formula on the motion of projectiles that described a parabola. He also hypothesized that matter was made up of particles that were infinitesimally small.

Galileo died on January 8, 1642. In 1822 the Church finally lifted the ban on the Copernican theories. In 1992, Pope John Paul II finally announced Galileo had been wrongly convicted.

Newton's Synthesis

Just consider the list of the various ideas Newton had to deal with in synthesizing a new scientific paradigm while also weeding out the parts that were wrong:

- Copernicus' heliocentric theory, but still clinging to many old elements of the Ptolemaic worldview
- Kepler's elliptical orbits but without gravity to explain a planet's variable speed Using Kepler's 3rd law, Newton figured that gravitational force is inversely proportional to the square of the distance between two masses.
- William Gilbert's theory of magnetic gravity, which though wrong, replaced the old idea of objects moving to a natural resting place
- Roberval's theory of universal gravity, but without mathematical proof
- Alphonse Borelli theory that centrifugal force kept planets from falling into the sun, but without mathematical proof.
- Huygens' mathematical proof for centrifugal force, but belief in perfect circular motion
- Descartes's discovery of the law of inertia, but belief in space full of ether
- Galileo's monumental work in astronomy, the laws of motion and math

Fluxions or calculus? Fluxions is what Newton called his new type of math that could dynamically plot rates of change over time. He invented it in 1665 (supposedly in one night) in order to solve a problem that the conventional math of the time couldn't handle. For the next twenty years, he kept his fluxions secret, even publishing papers without showing the advanced calculations it took to solve problems.

In the meantime, however, a German mathematician, Gottfried Leibnitz, invented this new type of math independently and publicized it, calling it calculus. Not until 1687, with his

publication of *Mathematica Principia*, did Newton finally publicize his fluxions, triggering a dispute that still goes on between British and German mathematicians over who discovered it first. Of course, the answer is they both probably did it independently. And if they hadn't, someone else probably would have done it soon afterward, because Western Europe was ready for it and needed it to push the boundaries of science to the next level.

There is evidence that Archimedes may have invented calculus in the third century B.C.E. Even if he did, the culture wasn't ready for it, so it was forgotten for 1900 years. Similarly, the Vikings may have discovered America around 1000 C.E., but it was Columbus' discovery 500 years later that made it stick. And if Columbus hadn't done it, the Portuguese explorer, Cabral most likely would still have crashed into Brazil eight years later.

Newton also delayed publishing the *Principia Mathematica* until 1687 because he wasn't sure if one should measure the gravitational pull of objects from their surfaces or centers. He thought the center, and was correct, but he wanted to be sure.

Among Newton's many interests was the nature of light. Previously, people thought that prisms created different colors of light. However, by shining a light through two prisms and showing the second prism had no further effect on the colors of the light, Newton showed that, rather than creating different colors of light, a prism merely separated a beam of light into its different colors corresponding to their wavelengths.

Another of Newton's innovations was his reflecting telescope. By using mirrors instead of refracting lenses, it could get a much clearer and more magnified image in a smaller chamber.

UNRAVELLING THE MYSTERIES OF THE HEART: WILLIAM HARVEY AND THE DISCOVERY OF THE CIRCULATORY SYSTEM

13th century depiction of arteries & veins

It seems amazing that the basic functions of the heart, circulatory system, and other bodily organs remained such a mystery to humans for so long, since they are so close to us and so vital to our very existence. However, early doctors faced serious obstacles in determining those functions. Religious taboos seriously limited the amount of human dissections taking place. Surgery's low status and primitive state is seen by the fact that barbers would typically double as surgeons, since they had the necessary cutting tools. Another major limitation was the lack of anesthetics to kill the pain. Heavy doses of liquor or a blow to the head were the closest thing to painkillers that doctors had before the 1800's.

As a result, people would rarely submit to surgery except in the most extreme circumstances (e.g., amputation for gangrene). And by then it was often too late. Without willing patients, surgery was rarely performed and could not advance. And without such advances, few people would risk operations. Caught in this vicious cycle, doctors had to resort to the dissection of animals. However, inferences made from animal dissections about human anatomy were often incorrect. Also, the practice of dissecting animals bled to death led to the misconception that only air flowed through the arteries and left side of the heart. This plus Aristotle's theory of four terrestrial elements led to various conclusions about human biology as seen in the theories of the dominant medical authority since the second century, the Greek physician Galen.

Galen's physiology. While Galen did clear up the misconception that only air flowed through the arteries, he also passed on several misconceptions.

For one thing, he said that air passes directly from the lungs to cool the heart, which is the seat of the soul, a furnace to heat the body, and the source of intelligence and blood in the arteries, while the liver is the source of blood in the veins. His second contention was that blood then flows out to the body, which absorbs the blood and does not recirculate it. Third, Galen said that air mixes with the blood to form a spirituous substance called *pneuma*. There are three kinds of *pneuma*, formed in the liver, heart, and brain, and controlling such things as the passions, senses, and consciousness. According to Galen, *pneuma* is the main source of the life process and consciousness in an organism. Finally, drawing upon Aristotle's theory of four terrestrial elements, there was the theory of the four humours (blood, bile, black bile, and phlegm), which must be in balance in order for one to be healthy.

These incorrect conclusions about human biology in turn led to two major misconceptions about disease. First of all, scholars saw sickness as a sign of an imbalance of the four humours that should be treated by bloodletting or other forms of purging. This supposedly would rid the body of imbalanced humours and cause it to restore the balance. This tied in closely with the second misconception: that disease is purely a result of internal balance, not external factors. Therefore, each person's disease was seen as a purely individual matter having no relationship to anyone else's disease, no matter how similar the symptoms may be

Despite the Church's support of Galen and feelings against dissection, problems started to arise with Galen's theories over time just through normal observations. This and two other factors, both leading out of the Renaissance, led to new research to figure out what the nature of the heart was. For one thing, the Renaissance artists placed increased emphasis on accurate representation of nature and human anatomy. Leonardo da Vinci's notebooks are the best-known examples of this emphasis on realism. Also, the printing press helped publicize and popularize these ideas within the medical community.

Second, in biology, as in physics and astronomy, the Renaissance oftentimes was not so important for breeding new ideas as for discovering other ancient authors that contradicted the accepted authority,

thus forcing scholars to seek the truth for themselves. Interestingly enough, the opposing authority was Aristotle, who differed with Galen on several points, claiming the life process was the product of all the various organs in the body, not of pneuma. This helped open up discussion on the life process and the nature of disease.

As with Aristotle, the combination of these factors generated a cycle that both undermined Galen and slowed down the creation of a new set of theories. New observations would be made that seemed to contradict his theories. This would lead to new explanations, once again framed in the context of the old beliefs, thus patching up the system. However, more observations would take place, leading to more patching of the old system, and so on. Eventually, the system would be so full of holes that someone would take the new data and synthesize it into a new set of theories that more accurately explained the universe.

Much of this research was done at the University of Padua, which was one of the main centers of research and new theories in the 1500's and 1600's. Being controlled by Venice, which had a bit of an anti-clerical tradition, the University of Padua encouraged the intellectual freedom needed to develop new theories that better explained nature. Copernicus and Galileo, had both worked there, as did most of the men who discredited Galen's theory and formed the modern theory of circulation. Two men in particular opened the way for challenging the old theories: Vesalius and Paracelsus.

Paracelsus (1493-1541) never received a medical degree, but he continued to teach, write about, and practice medicine. However, he taught from his own experiences, not Galen's books, and he taught in the vernacular. This was contrary to the Hippocratic Oath by which doctors were supposed to teach in Latin to prevent any trade secrets from getting into the wrong hands and being popularized. Paracelsus' actions made him an outsider to the medical community and caused him to challenge many of its most honored (and mistaken) theories and practices. One thing he claimed was that disease was the result of outside forces acting on the body, not an internal imbalance. Although he had no concept of germ theory, this idea opened the way for a new approach to diagnosing and treating disease. Paracelsus was reviled by the medical

establishment of his day, but became something of a folk hero to later generations and inspired further challenges to Galen.

Vesalius (1514-64) also took steps in overthrowing Galen and opening the way for a new theory on the heart and circulatory system. Unlike most medical scholars, who had assistants do the actual dissection while they read the appropriate passages from Galen, Vesalius did his own dissections and saw things for himself. He even saw things he was not looking for and that disagreed with Galen. He had a hard time believing that what his eyes saw was true and that Galen could be wrong. Nevertheless, in 1543, the same year that Copernicus (who also worked at Padua) published his book proposing a heliocentric universe, Vesalius published *De Fabrica*. This book, which was illustrated by the great artist Titian's own art students, provided anatomical drawings of unprecedented accuracy for medical manuals and set the standard for years to come. It also proved many of Galen's anatomical descriptions to be completely wrong.

Thanks to Vesalius and Paracelsus, more evidence kept coming in to cast doubts on Galen. In 1559, one of Vesalius' students, Colombo, published a description of how blood went from the right side of the heart to the lungs and then to the left ventricle. However, he still kept the traditional view that blood flowed *out* of the heart through both the arteries and veins. In 1574, Fabricius published a work describing valves in the veins preventing the outward flow of blood from the heart. Still, he refused to see that this meant the blood flowed from the veins *to* the heart. Instead he said the purpose of the valves was to keep too much blood from flowing to the veins from the heart. In 1606, Cesalpino observed blood flowing from the arteries to the veins and toward the heart. However, he also failed to grasp the meaning of this. As obvious as it should have been that Galen's system was not working, scientists' minds were too rigidly set to admit it. Finally, a man came along whose genius, like that of Newton and Mendeleev, was to synthesize the recent evidence into a new system that shattered the old views. That man was William Harvey, an Englishman also working at Padua.

Harvey, who was influenced by Fabricius' work on valves in the veins, developed very modern methods of observation and experimentation. In 1628, nine

years after his experiments confirmed his suspicions about Galen's system, Harvey published his findings in *De Motu Cordis* (Concerning the Motion of the Heart). The wealth of evidence it brought to bear effectively shattered Galen's theory forever.

Harvey showed that there was no septum (membrane) in the heart keeping arterial and venous blood separate while mixing blood and oxygen into *pneuma*. One thing he was not aware of was oxygenation. He pointed out that animals without lungs also had no right ventricle and, that in developing embryos, the blood took a shorter route from the right to left side of the heart. Harvey's most important and astounding contribution was the calculation that, in one hour, the heart pumps more than the body's weight in blood. This could only mean one thing: that the blood circulated from the left side of the heart, through the body, then to the right side of the heart, and from there through the lungs and back to the left side of the heart.

It took nearly half a century for Harvey's work to be accepted by the medical community. Once it was accepted, it provided a much better framework for studying the rest of the body. With the mysteries of the circulatory system unraveled, the respiratory and digestive systems could be better understood. And with those in place, other functions of the body could be figured out. Thanks to Harvey's brilliant synthesis, the way to modern biology was opened.

Galen: Better Living Through Pigs

Galen dissecting a sow

Galen (130-199 C.E.) of Pergamum was originally a surgeon in Asia Minor (modern Turkey) for gladiators, thus giving him plenty of opportunities to see the insides of humans. (In fact, for much the same reason, military surgeons have made many of the medical advances down to the 1800s.) His growing reputation advanced him to the “big leagues” of

gladiatorial matches in Rome, where he eventually became the primary physician for the emperor Marcus Aurelius.

Since autopsies were banned in Rome, Galen practiced mainly on monkeys and pigs (below), whose anatomies were seen as being closest to that of humans. In addition, Galen supposedly had opportunities to examine the corpses of victims of bandits or drowning. Ironically, while later physicians would insist on blindly following Galen’s ideas as found in his books, he himself was a strong advocate of doing one’s own dissections.

The role of the heart. Aristotle considered the heart the most important organ, being the seat of intelligence, motion, and sensation. Other organs, such as the brain and lungs existed merely to cool it. Galen largely agreed with Aristotle, but said its importance was secondary to the liver, which he said produced the bodily humours. He also disagreed with Aristotle, who said the heart was the source of the nerves. Most medieval authorities agreed with Aristotle that veins connect the liver to the heart, which distributes the vital fluids (*pneuma*) to the body through the arteries.

The four humours (blood, bile, black bile, and phlegm) corresponded to the four terrestrial elements in their qualities as follows:

Blood: corresponded to air (which is hot and wet), and also to the planet Jupiter, the apostle Mark, morning, spring, the heart, and the astrological signs of Gemini, Taurus, and Aries. Theophrastus, the successor of Aristotle in the Peripatetic school, stated that people with too much blood were bound to be sanguine (contented, positive) individuals.

Yellow bile corresponded to fire (which is hot and dry) Mars, the apostle Paul, noon, summer, the liver, as well as to Virgo, Leo, and Cancer. People with too much yellow bile, which medieval doctors claimed was manufactured in the gall bladder, were said to be bold and exuberant, but also choleric (cantankerous) individuals.

Black Bile corresponded to earth (which is cold and dry), Saturn, the apostle John, the afternoon, autumn, the spleen, and to Sagittarius, Scorpio, and Libra in the Zodiac. Individuals suffering from a disproportionately large amount of black bile in their bodies were said to be melancholic (gloomy).

Phlegm corresponded to water (which is cold and wet), the moon, the apostle Peter, evening, winter, and the signs of Pisces, Aquarius, and Capricorn. Individuals with too much phlegm in their bodies were said to be phlegmatic: not easily excited to action or display of emotion; apathetic, and sluggish.

Treatments. Before administering the notorious purgatives, such as bloodletting, to restore the balance of humours, physicians would generally prescribe other treatments. For example, if someone had a fever, he had too much hot and dry bile. So to increase his phlegm, which is cold and wet, he would have the patient take cold baths. If the patient had a cold, indicating too much phlegm, he would be told to bundle up in bed and drink wine to increase his bile.

Dissections before the late 1800s

Dissections were banned in Rome and the Muslim world, but not by the Church, and more public dissections were starting to take place in Western Europe in the 1300's. However, there was still a general uneasiness there about the appropriateness of dissecting cadavers.

Because of the lack of refrigeration, dissections were done quickly, continuously in one session, and outside over four days and nights, taking out the stomach and more perishable organs first and the bones last. They were also done publicly to ensure no malpractice. Fabricius made the first indoor amphitheater for dissections that could accommodate 300 observers. Because of the poor lighting, students would hold candelabras.

Typically, students would do the actual dissections, often by a body of water for convenient disposal of body parts. Meanwhile, the physician would be sitting at a safe distance

reading from Galen's text about what the students should be seeing. If students didn't follow directions (e.g., taking a right turn instead of a left turn at the spleen), what they saw wouldn't correspond to what Galen said. When told by students that what they saw didn't correspond with what he was reading from Galen, one physician, Jacob Sylvius, who was particularly attached to Galen's text, simply replied that this showed how much people had degenerated in 1400 years.

Most of the subjects were condemned criminals who were often dismembered or beheaded. Sometimes physicians, such as Vesalius, would know judges sympathetic to their work who would schedule executions at convenient times for dissections and even make the bodies available. Otherwise, getting cadavers was hard, often forcing physicians to rely on grave robbers. Dissections were well-attended public events, often held in amphitheaters to accommodate the huge audiences.

The aforesaid Jacob Sylvius Sylvius would sometimes show up with body parts up his sleeve to dissect. While this produced a sickening stench, his students wouldn't dare show their disgust. Noted for his greed Sylvius' gravestone has the following inscription:

*"Here lies Sylvius who never did a thing w/o a fee
Even in death, he grieves that you read this for free."*

Since there were few women criminals, there was relatively little information on female anatomy, a situation that would persist into the twentieth century.

The Outlaw Doctor: Paracelsus

"The universities do not teach all things, so a doctor must seek out old wives, gypsies, sorcerers, wandering tribes, old robbers...and take lessons from them."—Paracelsus

Doctors at that time kept their texts in Latin or Greek so no one else could understand them and they could prescribe drastic and powerful treatments and charge high prices. The world of doctors was one of separation: separation of books from bodies, separation of knowledge from experience, and separation of learned healers from those needing healing. Since it was unlikely that doctors would work to destroy their own establishment, an outsider was needed to shake things up, much as Galileo did in astronomy. Enter Paracelsus.

The name "Paracelsus" probably meant "equal to Celsus" (another Roman medical authority). Instead of a formal university education in the theories of Galen, his experience came from working in the Fugger mines in Tyrol and as a surgeon in the Venetian army. He never received a diploma of medicine or settled down.

Paracelsus had a mystical faith in the divine order in the human body, much like Kepler had in the harmony of the celestial spheres. He was also articulate, arrogant, and self-righteous, boldly announcing he would teach his classes based on his own experience. He even threw texts by Galen and Avicenna (a prominent Arab physician) into a student bonfire. Most controversial of all, he taught in the vernacular, which was against the Hippocratic oath, which prescribed teaching in Latin to protect the laity from incompetent practitioners.

Instead of internal imbalance of humours, Paracelsus said outside factors, such as minerals and stellar influences, caused diseases. Therefore, he largely analyzed from astrology. Although his specific arguments were wrong his general insights were right. So were many of his treatments. For example, his therapy for mercury poisoning (plasters and baths to draw out the mercury) are still used today.

Not that all his treatments were legitimate. He prescribed inorganic minerals and even metals for some ailments. He also claimed a plant's shape and color suggested what organ it was

suitable for (e.g., yellow plants for treating liver ailments).

Paracelsus' activities angered the medical establishment, which prevented most of his books from being printed while he was alive. After losing a case against a churchman who had promised a huge reward for curing him and then reneged on the promise, Paracelsus spent the rest of his life wandering around. After his death he became widely published and something of a folk hero celebrated by Christopher Marlowe, Goethe, and in the music of Berlioz.

Vesalius Turns Anatomy into Art

Vesalius (1514-64) was born under such favorable astrological signs that his mother saved his "magic" placenta. Growing up near the site of public executions, he saw lots of bodies and became fascinated with human anatomy. He read old medical texts avidly, but wanted to see for himself. He was a student of Jacob Sylvius of Paris, who was avidly pro-Galen. He was also one of the first to oppose Sylvius, earning the eminent professor's hatred ever since.

The amphitheater in Padua where doctors performed public operations, a popular form of entertainment before medical advances made it likely patients would survive such operations.

He then left Paris and did his own dissections on newly hanged criminals, introducing the practice of displaying newly removed organs to his students. In 1537, he became professor of anatomy at Padua, where he made anatomy

charts to help his students. Besides doing his own dissections, Vesalius, also created new surgical instruments or adapted existing ones for surgery.

In 1543, he published *De Humani Corporis Fabrica (On the structure of the Human Body)* with illustrations by Jan Stephan van Calcar, the artist Titian's favorite disciple. The front piece showed Vesalius doing a dissection, a human skeleton and a naked man. To further emphasize this was about human anatomy, not animals, the cover had two sullen barber-surgeons demoted to merely sharpening their instruments, and a dog and monkey in the bottom corners getting no attention.

Vesalius' book led to a violent quarrel with the rest of the academic community led by Sylvius. Since then, his book has made many medical authorities' top 10 list of important contributions to medicine, since it entirely reformed surgery. After this, medical students no longer had to endure the stench of flawed dissections to see what the human body looked like. Thanks to Vesalius, they could study accurate and detailed images of separate aspects of the body (nervous system, circulatory system, etc.) without having their views obstructed by other organs or systems, let alone blood and gore.

Vesalius served as the personal physician to both Charles V and Philip II of Spain. Supposedly he was once dissecting a woman and found her heart still beating. When her parents brought charges, the king just made him go on pilgrimage during which he died.

William Harvey Pulls it all Together

Harvey was educated at Canterbury, Cambridge, and Padua and worked at St. Bartholomew's Hospital in London (1609-43). He was very thorough in his experiments, using very modern methods: intense observations and experiments on which to base his hypothesis. In

one experiment he tied off an extremity, causing the arteries above and veins below to swell. In another, he had a strong man with clearly visible veins grasp a cylinder, making it easy to see blood in the veins flowing *toward* the heart. After a demonstration of blood circulation, a Swiss colleague declared: "I see it, but don't believe it."

As early as 1616, he had developed his heretical ideas about recirculation of blood, but delayed publishing his findings until 1628 from fear of the reaction. He had his book printed by an obscure printer in Germany, who used poor paper and made many mistakes. As Harvey feared, people called him mad, and his practice declined accordingly.

Invisible Worlds Below

Some early microscopes

*"We can easily conceive that in all rainwater which is collected from gutters and in all waters exposed to the air, animals may be found, for they may be carried thither by the particles of dust blown about by the winds."--
Antoine van Leeuwenhoek's first description of microbes*

The first image of bacteria

The invention of the microscope in the early 1600s revealed a world as startling as the moons of Jupiter that Galileo had

discovered, the major difference being that this was a world that surrounded and even existed within us.

One of the great pioneers was Antoine van Leeuwenhoek, who built over 400 microscopes, the most powerful of which could magnify an object 275 times. His descriptions of this new world capture the sense of wonder it inspired at the time. Leeuwenhoek described *“an unbelievably great company of living animalcules, a-swimming more nimbly than any I had ever seen up to this time. The biggest sort...bent their body into curves in going forwards.... Moreover, the other animalcules were in such enormous numbers, that all the water...seemed to be alive....”*

“And this being so, we must say that according to the rules of geometry a barley-corn or mustard seed is a thousand-million times larger” ...“thus we have reason to state that those very little animals are equipped with tails as well as limbs, mouth-parts and muscles, as the tails of Rats and Mouses .”

[Back to flowchart](#)

FROM FAITH TO REASON: DEISM AND ENLIGHTENMENT PHILOSOPHY

*"Nature & Nature's laws
Lay hid in night
God said Newton be
And all was light"
--Alexander Pope*

*"If God did not exist, it would be necessary to
invent him."--Voltaire*

Blinded by Science. Alexander Pope's short poem largely summarizes the impact that Isaac Newton's work had, not just on science, but also on the imaginations of his contemporaries. The 1700s abounded with heightened interest and discoveries in the sciences. Nobles and monarchs pursued different sciences as hobbies as well as funding serious research. In a popular play of the era, a woman even refuses to elope with her lover because she would have to leave her microscope behind. There were serious advances as well.

In astronomy, William Herschel showed that Uranus is a planet, not a star, that space is more vast than previously believed by demonstrating the Milky Way is not a cloud of gas but a whole galaxy of stars, and that so-called fixed stars were actually entire distant galaxies. Carl Linnaeus, using his system of binary nomenclature, catalogued the huge numbers of new plants and animals being discovered across the planet. In chemistry, Henry Cavendish isolated hydrogen; Joseph Black discovered carbon dioxide, and Antoine Lavoisier, separated water, supposedly an indivisible element, into oxygen and hydrogen. This destroyed Aristotle's theory of four elements and opened the way for the emergence of modern chemistry in the 1800s. And in medicine, Edward Jenner created a vaccine against the deadly disease, smallpox, although germ theory would not be developed for another century.

However, not everyone was impressed with the scientific progress of the day. Among them was Jonathon Swift who satirized much of contemporary society, including its obsession with science, in his book, *Gulliver's Travels*. In the following selection, Gulliver visits the science academy of the mythical Laputa, a land where everyone is so absorbed in

theoretical speculation that they have lost all touch with reality. Supposedly, he based this fictional account on real experiments being conducted at the time.

"The first Man I saw was of a meagre Aspect, with sooty Hands and Face, his Hair and Beard long, ragged and singed in several Places, His Clothes, Shirt, and Skin were all of the same Colour. He had been Eight Years upon a Project for extracting Sun-Beams out of Cucumbers, which were to be put into Vials hermetically sealed, and let out to warm the Air in raw inclement Summers. He told me, he did not doubt in Eight Years more, that he should be able to supply the Governors Gardens with Sun-shine at a reasonable Rate; but he complained that his Stock was low, and entreated me to give him something as an Encouragement to Ingenuity, especially since this had been a very dear Season for Cucumbers. I made him a small Present, for my Lord had furnished me with Money on purpose, because he knew their Practice of begging from all who go to see them.

"I went into another Chamber, but was ready to hasten back, being almost overcome with a horrible Stink. My Conductor pressed me forward conjuring me in a Whisper to give no Offence, which would be highly resented; and therefore I durst not so much as stop my Nose. The Projector of this Cell was the most ancient Student of the Academy. His Face and Beard were of a pale Yellow; his Hands and Clothes dawbed over with Filth. When I was presented to him he gave me a very close Embrace, (a Compliment I could well have excused.) His Employment from his first coming into the Academy, was an Operation to reduce human Excrement to its original Food, by separating the several Parts, removing the Tincture which it receives from the Gall, making the Odour exhale, and skimming off the saliva. He had a weekly Allowance from the Society, of a

Vessel filled with human Ordure, about the Bigness of a Bristol Barrel.

“There was a most ingenious Architect who had contrived a new Method for building Houses by beginning at the Roof, and working downwards to the Foundations; which he justified to me by the like Practice of those two prudent Insects the Bee and the Spider....

“I was complaining of a small Fit of the Cholick; upon which my Conductor led me into a Room, where a great Physician resided, who was famous for curing that Disease by contrary Operations from the same Instrument. He had a large Pair of Bellows with a long slender Muzzle of Ivory. This he conveyed eight Inches up the Anus, and drawing in the Wind, he affirmed he could make the Guts as lank as a dried Bladder. But when the Disease was more stubborn and violent, he let in the Muzzle while the Bellows was full of Wind, which he discharged into the Body of the Patient; then withdrew the Instrument to replenish it, clapping his Thumb strongly against the Orifice of the Fundament; and this being repeated three or four Times, the adventitious Wind would rush out, bringing the noxious along with it (like Water put into a Pump) and the patient recovers. I saw him try both Experiments upon a Dog, but could not discern any Effect from the former. After the latter, the Animal was ready to burst, and made so violent a Discharge, as was very offensive to me and my companions. The Dog died on the Spot, and we left the Doctor endeavouring to recover him by the same Operation...”

Another, even more biting satire by Swift was *A Modest Proposal Preventing the Children of Poor People in Ireland from Being a Burden to Their Parents or Country, and for Making Them Beneficial to the Public*, which suggested the Irish sell their children to rich British ladies and gentlemen for food. He sets up his readers by describing the plight of the Irish poor, and then shocks them with his outrageous suggestion. Not

only that, he sustains the irony by discussing ways to cook these children. "A young healthy child well nursed, is, at a year old, a most delicious nourishing and wholesome food, whether stewed, roasted, baked, or boiled; and I make no doubt that it will equally serve in a fricassee, or a ragoust."

Deism. The Enlightenment saw more than new advances in the sciences. In fact the very revolutionary nature of those scientific discoveries ensured that no field of thought would remain untouched. This was especially true of religion and philosophy, which had been so closely intertwined with the old scientific theories.

Starting with the rise of towns in the High Middle Ages, several historical forces converged to produce a revolution in European religion and philosophy. First of all, there was the Protestant Reformation. As we have seen, the Reformation led to a series of religious wars that ravaged Europe for nearly a century (c.1550-1650). One result of those religious wars was that many people grew tired of religion and looked for less restrictive modes of thought. Second, the Renaissance, with its interest in ancient Greek philosophies, gave rise to secular ideas that helped spawn the scientific revolution of the Enlightenment. This helped discredit the Church's old ideas on the universe and raise the status of humanity and its ability to reason on its own. Finally, the rise of towns led to resurgence of feudal monarchies into nation states. We have seen how they started challenging the Church's power during the turmoil of the Later Middle Ages. By the seventeenth century, some states were turning Protestant, while in Catholic lands rulers were using the doctrine of Divine Right of Kings to undercut the Church's authority in order to elevate their own.

All of these factors converged to undermine the role of blind faith in the Church's authority. While faith was still of prime importance, human reason was also an important element, especially in recognizing and avoiding the pitfalls of religious fanaticism and intolerance. After all, if God gave us the power to reason, should we not use it? As time went on the role of reason in religion increased while the role of faith declined correspondingly. Finally, reason completely replaced faith in a philosophy known as Deism. This was based largely on a Greek

philosophy, Epicureanism, which saw God as detached from worldly affairs. Our main purpose in life was to avoid pain, not through sensual self-indulgence, which ultimately brings pain, but through a reasonable and moderate way of life.

While Deism incorporated the Epicurean ideas and added its own twists, it was not an organized religion with a central dogma and places of worship. However, despite differences on various points, their beliefs can be summarized as follows:

- 1) God exists, but is detached from the affairs of this world. Drawing upon the mechanistic views of Newtonian science, they saw the universe as a giant clocklike machine that God had set in motion and then left to run on its own.
- 2) Religious truth can only be found through reason, not divine inspiration or clerical authority.
- 3) Miracles do not exist, only natural phenomena for which we have not yet found reasons.
- 4) Universal moral laws exist and can be found in all cultures around the globe, not just in Christian Europe. This reflected the exposure of Europe to other cultures in the Age of Exploration.

Deism was a philosophy mainly of an upper crust of intellectuals (known then as *philosophes*). Most people in the Enlightenment stayed devout church members totally untouched by Deistic ideas. However, although Deism was confined to a narrow upper class, including Thomas Jefferson in the United States, its influence was profound, since it was the ideas of these intellectuals who inspired the revolutionary ideas of the later eighteenth and nineteenth centuries. Deism also downplayed the role God plays in this world. This thrust more power and responsibility upon humanity to solve its own social, political, and economic problems, giving rise to remarkable new ideas in those areas as well.

An Age of Scientific Wonders

In the age's spirit of scientific experimentation, a group of people watches a lark suffocate under a bell jar as it is deprived of oxygen in Joseph Wright's *An Experiment on a Bird in the Air Pump*. The bird being suffocated is a cockatoo, probably a family pet based on the older daughter's reaction.

As a result of Isaac Newton's work and the growing belief in humanity's ability to understand, predict, and manipulate the laws of nature, science nearly assumed the status of a religion in the 1700s. It was an age of scientific wonders, not just in astronomy, but also in the other sciences as well.

The big name in astronomy in the 1700s was William Herschel, who made some 2500 discoveries, such as the planet Uranus, the Milky Way's vastness, and the Andromeda Nebula. While Uranus had been observed previously, people considered it a star. Herschel, however, judged it to be a comet because it moved too fast in relation to other stars. Because of its nearly circular orbit, it was eventually classified as a planet. Because of its nearly featureless appearance, Uranus is considered the most boring of the planets.

However, even the most brilliant minds of the day could have some rather eccentric beliefs, at least by today's standards. For example, Isaac Newton was a firm believer in alchemy and wasted a good deal of time trying to create gold out of base metals.

***Calculating the speed of light.* It was a Danish astronomer, Ole Christensen Rømer who first calculated the speed of light by measuring the time it took for Io, one of the moons of Jupiter, to reappear from behind the planet. When his calculations were 8-10 minutes off from his prediction, he concluded the difference was either due to variations in the speed of light or the different distances between Jupiter and the earth at the two times. Figuring (correctly) that**

the speed of light was constant he came up with the figure of 138,000 miles per second. Although his figure was 48,000 miles too slow, his reasoning was correct and, along with Herschel's discoveries, helped give people a much bigger impression of the size of the universe.

Making "elements" out of "compounds". One of the landmark experiments in chemistry was performed by Antoine Lavoisier who created water, which Aristotle claimed was an element, by combining two alleged compounds, oxygen and hydrogen, in a jar and striking a spark. Of course, by definition, creating an "element" by combining two "compounds" is impossible, which discredited the Aristotelian theory of the elements and set the stage for the revolution in chemistry in the 1800s.

Milkmaids and cowpox. Edward Jenner's inoculation against smallpox, although drawing upon older practices by the Chinese and other cultures, was the first successful inoculation against a major disease in Europe. However, it would not be until the 1800's that germ theory would be developed so that doctors actually understood how diseases worked. The line of reasoning leading to this discovery was the observation that milkmaids who contracted cowpox, a milder disease similar to smallpox, would henceforth be immune to the more deadly disease.

Jenner's inoculation consisted of scraping the pus from underneath cowpox scabs and introducing it through a small cut into a healthy subject. While they may get cowpox as well, they were also immune, or at least resistant, to smallpox for much, if not the rest of, their lives.

Initially, such a treatment met with popular resistance but was gradually accepted. Thomas Jefferson gained public acceptance for vaccination by having his entire household, including slaves, inoculated, while Napoleon ordered vaccination for his entire army. In 1979,

the World Health Organization declared smallpox extinct (except for a few specimens kept in selected labs). While plagues and epidemics would grab the headlines, before Jenner, smallpox may have been consistently responsible for as many as one in fourteen deaths year in and year out. As a result, some people claim that Jenner saved more lives than anyone else in history.

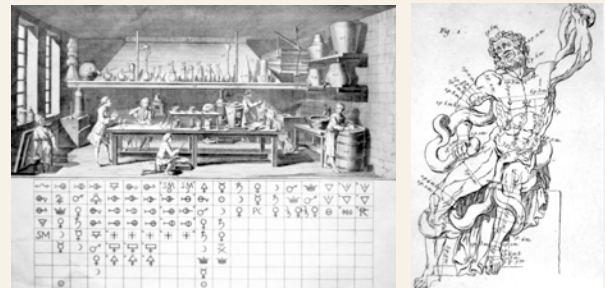

Despite Jenner's work, the theory of Humours and the use of purgatives would still dominate medicine for years.

The Chronometer, grandfather of the GPS.

A major problem for transoceanic navigation was time keeping on ships so that navigators could calculate longitude. Finally the Royal Society of London offered a large reward of £25,000 to anyone who could solve this problem. In 1761 John Harrison (above) won the contest with the invention of the chronometer, building upon Huygens' pendulum clock to create the grasshopper escapement, thus opening a whole new age in global navigation.

Diderot's Encyclopedia.

Two pictures from Diderot's encyclopedia: an alchemist's shop with a table of elements they imagined and measuring the dimensions of the Laocoon

One of the landmark events of the Enlightenment was the publication in 1751 of Denis Diderot's *Encyclopedie*. Its purpose was to

summarize in its 36 volumes the rapidly expanding fields of human knowledge that the Scientific Revolution was creating. It covered a wide and diverse array of topics ranging from history and philosophy to practical arts and crafts such as stitching nets, infantry training, and handwriting. More than 200 scholars assisted in this work, which included 11 volumes of plates to illustrate its topics.

Linnaeus' binary nomenclature. With the vast numbers of new plants and animals being discovered in Europe and abroad came a growing need for a system of classifying all this new data. That system was the brainchild of Carolus Linnaeus, who identified 12,100 species of plants, dividing them by sexual characteristics and placing them into 24 categories. Out of this came his system of binary nomenclature: giving first the genus or family name and second the species name. The full system of classification had five levels: Phylum, Class, Order, Family, Genus, and Species. Linnaeus' *Systema Naturae* would go through twelve editions in his lifetime and is still the basis for classifying living beings.

Toward a theory of evolution. In the realm of Natural History, Georges Louis Leclerc Buffon published a 36-volume *Natural History* (1749-88). Among his more radical ideas: animals vary according to their natural environments; the earth is 75,000 years old, rather than 6,000; animals have changed since creation and climate change has been partly responsible. He did stop short of claiming common descent with apes (even though he had a trained chimp). The University of Paris forced Buffon to issue a public apology for such preposterous ideas. Despite that, he is seen as the most influential name in natural history in the 1700s and a precursor to the idea of evolution.

Blinded by Science

Nobles on a scientific outing. Notice how they are looking through the wrong ends of their telescopes.

Even the most brilliant minds of the day could have some rather eccentric beliefs, at least by today's standards. For example, Isaac Newton was a firm believer in alchemy and wasted a good deal of time trying to create gold out of base metals. Therefore it shouldn't come as a surprise that many people were duped into believing the most outrageous claims, be they ridiculous scientific theories, financial scams, or just reports of women giving birth to rabbits.

The Great Lunar Man-Bat Hoax. In 1835, a reporter, Richard A. Locke, under the false name of Dr. Andrew Grant, a supposed companion of the astronomer, John Herschel, published a six part article in the *New York Sun* describing life on the moon, including unicorns, bipedal beavers and bat-winged humanoids as seen through Herschel's giant telescope. Locke also falsely claimed that Herschel believed there was life on other planets, including the sun, whose people had abnormally large heads, since small heads would explode from the heat.

Unfortunately, according to Locke, he couldn't show these wonders to anyone because the sun caused Herschel's giant telescope to act as a burning lens that caught the observatory on fire and burned it down.

Meanwhile, circulation for the *New York Sun* skyrocketed, establishing it as a major newspaper from the time on. Although the hoax was revealed several weeks later, the *Sun* never retracted the story.

A popular pseudo-science of the age was physiognomy, and its offshoot, phrenology, which claimed to tell a person's character by his or her facial features and how they compared to other animals. For example, according to the

18th century phrenologist, Johann Lavater, the eagle's "lightning glance" showed a regal character, the camel's jaw showed dullness and lack of courage. The man's strained grimace revealed his stupidity, while the elephant's broad forehead indicated a retentive memory.

A scam of a different sort was that by Mary Tofts (above) who allegedly gave birth to rabbits. She claimed that, while pregnant, she had an intense craving for roast rabbit. Even after a miscarriage, she still was obsessed with the little critters until one day in 1726 she "gave birth" to nine of them. Based on her story, doctors explained the births as a result of "maternal impressions", claiming a pregnant woman's experiences could be imprinted directly on a fetus at conception and cause birth defects. The "rabbit woman" confessed only after a porter admitted to being part of the hoax.

The age also had its share of investment schemes/scams designed to exploit people's gullibility and greed to relieve them of their money. Most notable among these were the South Sea Bubble and the Mississippi Bubble. As the term *bubble* suggests, both of these schemes kept expanding until they burst, ruining a lot of people's dreams with them.

He also had a glass harmonica, also known as hydrocrystalophone, or hydrodaktulopsychicharmonica, which translated from Greek meant "harmonica to produce music for the soul by fingers dipped in water," to provide ethereal and calming music.

A short history of electricity

Let's start with the heavy plow, which dramatically improved agricultural production...

Which led to dramatic population growth in Europe...

That could support the rise of towns...

That led to the rise of kings...

That led to bigger armies for bigger wars between nation states...

That led to the development of gunpowder...

That led to the need for more \$\$\$\$\$...

That led to a mining boom in Germany in late 1400s...

But this led to another problem: water seepage in mines and the fact that a suction pump could only raise water 32 feet.

But why? A student of Galileo's, Evangelista Toricelli, thought he had the answer: the weight of air pressure pushing down on the water.

Since 32-foot long tubes were unwieldy, Toricelli used 6-foot tubes of mercury, which is fourteen times the weight of water. He upended these tubes in a vat of mercury, calculating the air pressure would stop the mercury from dropping at about 30 inches (one-fourteenth of 32 feet). Not only was he correct in that prediction, but also that what was left at the top of the upended tube was a vacuum, which Aristotle and Galileo thought were theoretically impossible, because an accelerating object in a vacuum would continue accelerating indefinitely to infinite speed, which is ridiculous.

Not only had Toricelli invented the barometer, he also triggered all sorts of experiments with vacuums and, by extension, electricity.

One experiment was Von Guericke's demonstration of the power of the vacuum in 1650 where he had two teams of horses try to pull apart two metal hemispheres joined together by a vacuum. They couldn't do it.

Even more intriguing, what would happen if you spun a barometer around in the air?

That's exactly what the famous French astronomer, Jean Picard, did while strolling down a Paris street in 1675. The result: the barometer started glowing, giving off what people called the barometric light or the "glow of life." What Picard had done was generate an

electrical charge, which he didn't understand. But it still excited people all over Europe and inspired all sorts of fun experiments with primitive electrical generators, such as Hauksbee's Influence Machine.

People even went on tour, putting on cheap "dog and pony" shows with Hauksbee's Influence Machine, demonstrating the power of electricity. Such traveling shows were popular in the 1700s. A common stage trick was to charge up a girl on stage and have a man from the audience come up to kiss her, giving him a shock that would knock him off his feet. This also inspired more substantial experiments with electricity.

One serious problem concerned all the fires and explosions (of powder magazines) caused by lightning strikes. Previously, a common belief and practice on how to drive off lightning storms was to ring a town's church bells. Unfortunately, a bunch of young men hanging from giant pieces of metal in the highest part of town led to a lot of "dead ringers" (which, by the way, is not the true etymology of the expression).

After hundreds of deaths caused by lightning hitting church bells over the years, the French government outlawed this practice. Still, the problem of lightning starting fires, and especially detonating towns' powder magazines, persisted.

Besides saving people from a lot of lightning strikes, Franklin's lightning rod inspired a new fashion trend in lightning rod bonnets & umbrellas. There are no reliable figures on how many lives they saved.

Another use for electricity was therapeutic, people believing it could solve medical problems. For example, there was James Graham's Temple of Health with its celestial or Magnético-electrico bed on top of an electrical field on which childless couples could conceive (with the help of exotic dancers). More commonly "therapists" would connect electrodes to the ailing parts of patients' bodies and zap them. Even little girls weren't safe from these quacks.

Then there was Franz Mesmer's "animal magnetism", which combined the "therapeutic" effects of electricity with hypnotism. Mesmer believed that the universe is pervaded by a mysterious substance he called "animal magnetism", and that illness was caused when it was out of balance. Thus, he would hook ailing patients up to a battery, then "mesmerize" (i.e., hypnotize) them while also charging them up. He also had a glass harmonica, also known as hydrocrystalophone (below right), or hydrodaktulopsychicharmonica, which translated from Greek meant "harmonica to produce music for the soul by fingers dipped in water," to provide ethereal and calming music.

Patients swore by Mesmer's treatments. Although he claimed it was the electrical treatments that cured his patients, it was probably the post-hypnotic suggestions that

came with his “Mesmerism”. An investigative committee headed by the famous chemist, Lavoisier, discredited Mesmer as a fraud, even his claim that he could magnetize the sun. As off as his claims about “animal magnetism” were, his work with mesmerism inspired later research in the therapeutic use of hypnotism.

The Wit and Wisdom of Voltaire

Among other things, Voltaire was particularly renowned for his short pithy sayings. Following are some of his more memorable ones.

"Theology amuses me. There we find Man's insanity in all its plenitude"

"Killing is murder unless it is done to the sound of trumpets"

"To stop criticism they say one must die."

"All the reasoning of men is not worth the sentiment of one woman"

"It is said God is always on the side of the big battalions."

"If God did not exist, it would be necessary to invent him."

"Self-love never dies"

"Marriage is the only adventure open to the cowardly"

"In general, the art of government consists in taking as much money as possible from one class of citizens to give it to the other."

"I do not agree with what you have to say, but I'll defend to the death your right to say it."

"Anyone who has the power to make you believe absurdities has the power to make you commit injustices."

"Faith consists in believing when it is beyond the power of reason to believe."

"God gave us the gift of life; it is up to us to give ourselves the gift of living well."

"Love is a canvas furnished by nature and embroidered by imagination."

"I hate women because they always know where things are."

"God is a comedian, playing to an audience too afraid to laugh. "

"Judge a man by his questions rather than his answers."

"Every man is guilty of all the good he did not do."

"Anything that is too stupid to be spoken is sung."

"Those who can make you believe absurdities can make you commit atrocities."

"The art of medicine consists in amusing the patient while nature cures the disease"

"No snowflake in an avalanche ever feels responsible."

"If God created us in his own image, we have more than reciprocated."

"If you have two religions in your land, the two will cut each other's throats; but if you have thirty religions, they will dwell in peace."

"It is dangerous to be right when the government is wrong."

"A great many laws in a country, like many physicians, is a sign of malady."

"The best way to become boring is to say everything."

"All sects are different, because they come from men; morality is everywhere the same, because it comes from God."

"England has forty-two religions and only two sauces."

ENLIGHTENMENT POLITICAL & SOCIAL IDEAS

"Killing is murder unless it is done to the sound of trumpets." --Voltaire

The Enlightenment was a period of nearly unbounded optimism and faith in the human race's ability to solve its own problems, including restructuring government and society along more reasonable lines. There were two main factors leading into this search for a rational approach to creating a better society. First of all, Deism, with its idea of a God detached from our affairs, gave us the ability and responsibility to solve our own problems. Second, this was a time of rapid social and economic change, especially in England with its booming colonial empire and economy. London's population jumped from c.700,000 in 1715 to 2.7 million by 1815. Such rapid growth led to squalid living conditions, alcoholism (gin consumption increasing 10 times), drug abuse, and crime. While Deism may have given us the power and responsibility to reform society, these conditions provided an urgent need for such reforms. The result was a flurry of new ideas in political science, economics, psychology, and social reform.

Enlightenment ideas on politics were rooted in John Locke's *Two Treatises on Government* (1694). Locke's basic idea was that government, rather than being at the whim of an absolute monarch with no checks on his power, existed as a trust to carry out the will of the people and protect their "lives, liberty, and property." If it failed in its duties or acted arbitrarily, the subjects had the right to form a new government, by revolution if necessary.

Locke's ideas largely summarized the achievements of the English Revolution of the 1600's. They had a tremendous impact on political thinkers in France chafing under the corrupt reigns of Louis XV and Louis XVI. Three of these men, Montesquieu, Voltaire, and Rousseau would profoundly influence French political thought and provide the theoretical justification for the French Revolution.

Montesquieu, sometimes seen as the father of political science, looked at various types of

government and analyzed what made them work in his book, *The Spirit of the Laws*. Among the ideas he supposedly derived from England was the separation of powers in government, a vital part of our own constitution.

Voltaire, who first made his name by championing the cause of a Jew wrongly accused and executed for a crime, was probably the most famous of the Enlightenment philosophers. Voltaire wrote on a wide range of topics, but should be remembered here for advocating more civil and political liberties, at least for educated people who can understand the implications of their actions. Voltaire was less clear on what rights the illiterate masses should have.

Finally, there was Rousseau who said that people could only legitimately follow laws they themselves have made. Otherwise, they were the victims of someone else's tyranny. Therefore the ideal state is a small-scale democracy in which everyone participates. Together, the ideas of Locke, Montesquieu, Voltaire, and Rousseau provided the basic ideas we have today on personal rights and liberties and how a government can best be structured to guarantee those rights and liberties.

In economics, the most important figure was Adam Smith, whose *The Wealth of Nations* pushed for a wholly new attitude toward economics. Smith saw people as selfish and willing to work much harder and produce much more if they had the incentive to do so. He saw the mercantilism of the 1600's and 1700's, where the state tried to import gold and silver while exporting its goods, as stifling to an economy. Therefore, doing away with mercantilist monopolies and restrictions would provide more incentive to produce. There was no need to regulate the market since people's greed and the law of

supply and demand would make the market self-regulating. Smith's free market policy, known as *laissez faire* ("hands off") was widely adopted in the 1800's as Britain, Europe, and the United States rapidly industrialized. It is still a vital part of our economic thinking today.

In psychology, there was Helvetius, who claimed our minds and personalities are blank slates at birth and that we are the products of our environment and the sum total of our past experiences. Combining Helvetius' "blank slate" theory with the prevailing optimism of the age was Jeremy Bentham. He felt we could teach people to act in rational ways by providing an ideal environment where they can learn the right sorts of behavior. Bentham's movement, Utilitarianism, became quite popular and pushed for a wide range of social reforms in such areas as prisons, law codes, and public health. Bentham even claimed he could use calculus to quantify how much pleasure someone got from a particular experience.

See the reading on flowchart 1.3 for further discussion of the nature vs. nurture argument.

Another development came in the realm of child psychology. Before the Enlightenment, children were largely seen as miniature adults. Among the upper classes, they were typically dressed in restrictive clothing mimicking that of their parents and turned over to nurse maids right after birth. They might get to see their mothers for a short period each day, but often had little or no more contact than that with their parents. However, two things happened to start changing society's perception of childhood as a stage (or several successive stages) of development.

One was Rousseau's *Emile*, an educational tract that pushed for age appropriate education. For example, instead of making 5-year olds memorize all the countries on the globe, which would be meaningless to them, Rousseau advocated they get a sense of place by exploring their own neighborhoods and gradually branching out from there as they got older. *Emile* still has a profound impact on modern educational theory and practice.

The second factor leading to new attitudes toward childhood also had to do with Rousseau. Spurred partly by the high death rate of babies of poor

working women who could not afford decent child care, he led a movement for better and more natural child-care, including mothers nursing their own babies and personally raising them rather than turning them over to nurse maids and nannies. Since then, there has been a growing tendency for parents to be personally involved in their children's upbringing, a major factor in the modern family.

William Hogarth: Eighteenth Century Britain's Social Conscience

William Hogarth was an 18th century British artist whose work served as a sort of national conscience on the country's various social problems such as alcoholism, financial scandals, and the immoral lives of the rich. Along those lines he did *The Rake's Progress*, a series of paintings on the wasteful ways and demise of a typical son of the newly rich. It starts as he has inherited a fortune and he is being fitted with expensive new clothes. Meanwhile, he is confronted by the angry mother of his girlfriend whom he has gotten pregnant. From there, things go downhill as he squanders his fortune, gets another one by marrying a rich old maid, losing that fortune too, going to debtor's prison and finally ending up in London's insane asylum, Bethlehem Hospital (below), from which we get the word Bedlam.

Treatment of the mentally ill was especially brutal back then as they were often caged, chained to walls, and beaten (to "beat some sense into them"). To help finance the institution, tours were given to during which the inmates would be encouraged to their bizarre antics for the entertainment of the guests. The recently discovered process of distilling liquors helped lead to rampant alcoholism and more people being diagnosed as insane for the resulting behaviors.

Crime was a major problem in eighteenth century London. While poverty was certainly a primary contributing factor, so was the criminal law code, which listed 200 different offenses that carried the death penalty. Since there were so many relatively minor crimes that one could be executed for, juries were often reluctant to convict people for transgressions they obviously had committed. So they walked.

Adam Smith's Pin Factory

Adam Smith's theory on pin manufacture was probably the most dramatic example of how division of labor can increase production. According to Smith, one worker carrying out all the steps in the production of a pin could manufacture a maximum of 20 pins per day. However, dividing the procedure into different tasks between 10 workers would increase production by a factor of 240 times to 4,800 pins per worker per day. This is how Smith described the operation of a typical pin factory of the time.

“One man draws out the wire, another straightens it, a third cuts it, a fourth points it, a fifth grinds it at the top for receiving the head: to make the head requires two or three distinct operations: to put it on is a particular business, to whiten the pins is another ... and the important business of making a pin is, in this manner, divided into about eighteen distinct operations, which in some manufactories are all performed by distinct hands, though in others the same man will sometime perform two or three of them.”

It's worth noting that before industrialization and the factory system, the production of such labor intensive items as pins and nails made them much more expensive than now. Nails, in particular, were used quite sparingly in wood construction throughout history, variations on the mortise-and-tenon technique being favored, although it drastically slowed down construction.

Pigeon missiles

During World War II missiles, such as the German V-2, could be programmed to hit stationary targets. However, finding and hitting moving targets, in particular battleships, was another matter. Building on his research with

pigeons, B. F. Skinner pitched an idea called Project Orcon using trained pigeons to guide the missiles. The pigeons would be pre-trained to peck at pictures of the chosen target, getting a treat only when they hit the photograph directly. Eventually, they became so good at their job that they could even follow a moving target, engaged in a feeding frenzy of pecking the whole time they could see it.

Being sufficiently trained, three pigeons would be stuffed into the nose of a rocket at 120° from one another to give a 360° view of their surroundings. A series of reflectors inside the nosecone gave the pigeons a view outside of the missile. The reflectors were hinged so that the pecking would alter their orientation and cause the missile to shift in the direction of the target. Skinner received \$25,000 for the experiment, which was initially successful. However, improved electronic guidance put an end to the project.

During the 1970s, the U.S. Coast Guard conducted a similar experiment, this time for search-and-rescue missions. Conditioned by stimulus-response training, whenever they saw the desired target pigeons would go into a feeding frenzy and peck at the screen, which had sensors that turned the helicopter in that direction. The pigeons' success rate was 93% compared to only 38% for humans, partly because they didn't get bored from hours of staring at the featureless vastness of the ocean. The project was abandoned in 1983, however, because it had the unfortunate side effect of causing helicopters to crash into one another.

From Rococo Sensuality to Pre-Revolutionary Sentimentality and Virtue

The age of religious wars helped lead to two things, one cultural and the other political. Culturally, the seemingly endless fighting had discredited religion and fostered a more secular outlook. The result was the age of Enlightenment that especially stressed reason, secular philosophies, and the newly emerging modern sciences. Politically, the turmoil of the last century created a desire for more stability, giving rise to the Age of Absolutism along with

the prominence of the nobles and their values. Together, these produced a very ornamental style of art known as Rococo that typically had lighter, sensual, and more secular themes to suit the nobles' tastes, such as Fragonard's *The Swing* (left) and Boucher's *The Love Letter*.

Toward a new sentimentality. In November 1755, an earthquake that took thousands of lives devastated Lisbon, Portugal (below). It also seriously shook people's largely unbounded faith in our ability to control our lives. This triggered something of a reaction away from unlimited faith in science and toward an emphasis on emotions and feelings.

Typical of this shift was Voltaire's reaction to the Lisbon earthquake of 1755, the satirical novel, *Candide*, where the title character goes through an unbroken string of catastrophes such as the inquisition, war, and the Lisbon earthquake. Besides all this, Dr. Pangloss, *Candide's* mentor, glosses over all these disasters with the Enlightenment belief that all they are all ultimately for the better, while ignoring the suffering continuing all around him.

In the Americas Candide, while viewing a slave with an amputated foot, is confronted with the awful price of sugar Production

The new sentimentality that emerged was largely a reaction against the cold rationality of the earlier Enlightenment. Jean Baptiste Greuze's paintings especially show the late Enlightenment movement towards what we would view as excessive sentimentality, a transitional stage to Romanticism, the next great cultural movement that would accompany the age of revolutions. Besides lots of saccharin sweet pictures of beautiful children, he also portrays the sadness of a widow mourning her husband, young girls weeping over the deaths of their pet birds, and even a woman crying over a broken mirror.

Just as new attitudes toward children were emerging in the later Enlightenment, there was a new middle class attitude toward the family replacing the nobility's notorious lack of marital fidelity. Artists such as Boucher and Fragonard, who earlier were known for doing sensuous paintings devoid of emotion, started focusing on sentimental scenes of family life, mothers with their children, such as Boucher's family breakfast scene below.

The new virtue. Parallel to the new sentimentality was a reaction against the selfish and amoral values of the nobility toward a new emphasis on virtue. Even Fragonard and Boucher, who were famous for their sensuous paintings, switch to doing paintings emphasizing love and virtue. Two of Fragonard's paintings, both entitled *The Stolen Kiss*, illustrate this in two different ways. While one is a somewhat sweet picture of a young man stealing one last kiss from his girlfriend who is obviously worried about getting caught, the other depicts a woman defending her virtue against the unwanted attentions of a young man.

getting the most prestigious seats, meaning those closest to the royal box. However, the most prestigious seats didn't necessarily give the best view. Therefore, seats with a better line of sight to the stage were the most expensive, and went to those with the most money, who were not necessarily high-ranking nobles.

On a broader level, the renewed concern for virtue showed itself in a growing movement promoting civic virtue. Even if artists couldn't openly criticize the monarchy and push for a more democratic society, they could extol the virtues of the democratic and civic spirit of the ancient Greeks and Romans who were willing to, work, fight, and even die for the good of the state and society. The result was another school of art known as Neo-classicism, in which paintings, such as Jacques Louis David's *Oath of the Horatii*, could promote democratic and civic values without facing charges of treason against the king.

Elizabeth Vigée-LeBrun's painting of Marie Antoinette and her Children shows that the new attitude toward children had even influenced the upper classes by the French Revolution.

[Back to flowchart](#)

Towards a more democratic society and the French Revolution. Various aspects of European culture reflected a growing trend toward a simpler more democratic society. In ballet, stories often concerned simple, but always beautiful, peasant girls. Of course, some, more conservative audience members were outraged at this choice of subject, but overall, audiences embraced this new twist. Helping this glorification of the peasants was the French queen, Marie Antoinette, who had a mock peasant cottage where she could dress up as a peasant, tend her garden, and feed her petting zoo. Although highly contrived and not even getting close to the hard life the peasants actually lived, it did affect fashions and hairstyles, which became simpler as the Revolution approached.

In a way, even seating in the theaters became more democratic. Previously, seating had been based on social status, higher-ranking nobles

ENLIGHTENMENT, REVOLUTION, & WOMEN'S CHANGING ROLES

While women during the Enlightenment made little, if any, visible progress toward equality, there were two lines of development that helped pave the way for the Suffrage Movement in the 1800s. One was philosophical showing changing views about women among intellectuals. The other was social, the phenomenon of intellectual salons held by women, first at Versailles, and later away from court.

Changing philosophical ideas. Crucial to changing views about women were the broader ideas about liberty and equality espoused by men such as Voltaire and Rousseau. While philosophes were talking about equality only between men, this did open up some discussion about how women fit in and whether they should be accorded full status as rational human beings or be treated somewhat like children. One issue relevant to this question was slavery, which Enlightenment philosophes generally condemned, opening the way for women to say the same arguments should apply to their lower status, which some would even characterize as a form of bondage. Along those lines, many philosophes, such as Montesquieu, Voltaire, and Diderot, conceded that women were rational beings just like men, although they didn't go so far as to advocate equality for women.

Another set of discussions revolved around the idea that women were closer to nature than men. While a more positive view of nature was emerging, as seen in much Romanticist art, the view that women were closer to nature led to some contradictory conclusions. One view was that women, being closer to a state of nature, were therefore less rational and should be confined to a domestic role. However, there was also the view that since Nature is good, women were as good as men.

Overall, these discussions led to a more positive view of women, despite the views of Rousseau and various Enlightenment doctors that women were distinctly inferior to men.

Enlightenment salons. In the late 1600s, Louis XIV's court at Versailles dominated France both socially and intellectually. While women were expected to confine their conversations to petty

“feminine” gossip, there were some women of high social status who started holding meetings on intellectual matters in their quarters. At these meetings, known as salons, the guests were men of lower social status, so the hostesses could set the agenda and join in the conversations.

After Louis XIV's death in 1715, the social and intellectual center of France moved from Versailles to Paris, and so did the salons. Although these venues were more public than at Versailles, they were still hosted by women, which was considered compatible with their perceived domestic roles. The hostesses took increasingly active roles in the discussions and, in some cases, even got their own works published. This opened the way for other women, such as the artist Elizabeth Vigée Lebrun, to make their marks.

The Age of Revolutions (1789-1848). Then, in 1789, came the French Revolution, which inspired what until that time was the supreme statement advocating women's equality, Mary Wollstonecraft's “Vindication of the Rights of Women” (1792). Her basic argument was that women are not naturally inferior to men, but only seem to be because they lack the same educational opportunities. Her work is considered one of the cornerstones of the modern feminist movement. The French Revolution also saw significant involvement by women, who hoped their contributions (e.g., the March of the Heroines in 1789) would gain them more rights. Unfortunately, the Revolution gave way to the militaristic culture of the Napoleonic era and a backlash that put women back into subservient status.

Women's fashions during and after the Revolution reflected both the aspirations of some women and how quickly they were dashed. Before the Revolution, a primary element of any upper class woman's wardrobe included huge and ponderous powdered wigs along with the corset, a highly restrictive undergarment going back to the 1500s that shaped a woman's figure to conform to prevailing standards of beauty (as defined mostly by men). Some would say that the highly restrictive nature of the corset reflected women's social status. During the Revolution, women started wearing much looser dresses and natural hairstyles that reflected both the Neo-Classical movement and women's (briefly) improved status. However,

women's behavior and activism during the Revolution shocked many men. Therefore, after Napoleon's defeat in 1815 and through the rest of the 1800s, the corset made a comeback along with a new device to accent another part of a woman's figure, the bustle. Although huge powdered wigs did not make a comeback, women were covering their heads with an array of hats. Ironically, the bonnet was originally designed after ancient Greek military helmets.

There were also marked changes in men's clothing and behavior that would more starkly differentiate their role from that of women. Before the Revolution, men were clean-shaven and their attire was much more colorful and fancy, including silk hose and powdered wigs, (although not as ponderous as what women wore). Behavioral standards were also different. For example, it was more acceptable for men to show emotion, including crying, and even to remark on another man's legs. The militaristic atmosphere of the Napoleonic era and its aftermath changed all that. Facial hair, at first sideburns and later on moustaches and beards, made a comeback in the 1800s. Thanks largely to an Englishman, Beau Brummel, men's attire became duller, largely reduced to black or grey jackets and white shirts. The only concession to color was the necktie.

Therefore, after a brief flirtation with more freedom during the French Revolution, women were pretty much knocked back to their previous subservient domestic status. This situation would last until conditions made possible by the industrial revolution would provide opportunities for the rise of the suffrage movement in the late 1800s.

A day in the Life of an Eighteenth Century Lady of Leisure

For the upper classes, the Enlightenment was largely a time of strict manners and loose morals. Much of this came from the fact that most marriages were arranged on the basis of money and status, rarely for love. Therefore, it was common to find love and passion outside of marriage. For women, this was trickier, for two reasons. For one thing, they were more closely watched and confined than men were. Secondly, they had to be careful about getting pregnant.

There were herbal mixes available that could induce abortions, but they were both extremely painful and dangerous.

However, where there's a will, there's a way, and upper class women found ways to circumvent society's restrictions, and there were plenty of men willing to cooperate. As the philosophe Montesquieu put it: "...a husband who would wish to have sole possession of his wife would be regarded as a disturber of public happiness." Marital separation was simply done by the husband slapping his wife before two witnesses. Less publicized were the many marriages that were happy and faithful.

After rising and taking a bath (typically while still wearing a nightgown), the lady would attend the toilette where she had her hair and makeup done. This was a semi-public affair, with friends, lovers, hairdressers, and maybe even the lady's husband, gathered to relate new rumors or give old rumors clever new twists.

After this might be a promenade in the park. Special days and hours were established for young ladies to display themselves as a public spectacle for any gentlemen who were present, sort of like speed dating, but slower. If a lady caught the eye of a gentleman, he would inquire about the name and status of the lady so he could make his move. If she were interested, she had fewer and more subtle options to show her interest, such as "accidentally" dropping her handkerchief in front of him, so he could pick it up and present it to her.

The lady's day would then be filled with various social activities. One was the music lesson. A truly cultured lady should only practice on a graceful instrument (e.g., harp). Oftentimes she had her lesson in the presence of an attentive gentleman in order to impress him. Later a

friend might visit for conversation, which was also seen as an art typified by *"a gay dialogue in which each listens but little, yet speaks...in a rapid prompt and vivacious manner."* Another popular activity was cards, in particular the game of Whist. Given their otherwise idle lives, many men and women became addicted to cards and gambling. One woman was so hooked that, when attending a friend's deathbed, she brought along her cards, table, and friends.

Of course, the highlight of the lady's day would be when a gentleman came to court her. One picture of the time shows such a man professing his undying love to the lady in the garden, with her mother or aunt listening closely from behind some bushes (below).

The lady might also have the occasion to read love letters from her boyfriend. Some of the meaner spirited women would read them aloud to their friends for laughs. Napoleon's wife, Josephine Beauharnais, did this while he was on campaign in Italy and she was having an affair with a young captain back in Paris. She paid for it when he found out.

Madame de Pompadour

Madame de Pompadour was Louis XV's official mistress, a position that one only obtained after interview with the queen and her approval. Besides an official mistress, Louis had numerous

girlfriends for one-night stands. He especially preferred young virgins so that he could not contract venereal disease from them.

Louis met Madame de Pompadour at a masquerade ball where he and his friends were all disguised as well-trimmed yew trees. Even after he had moved on to other mistresses (whom she herself screened), she remained a close confidante of the king.

This was not necessarily a good thing, as she had a personal grudge against Frederick II (AKA The Great) of Prussia, who had a particular talent at arousing the ire of women, including empress Maria Teresa of Austria and Tsarina Elizabeth I of Russia. Apparently, Frederick had two greyhounds that were constant companions, even sleeping at the foot of his bed. He had named one of them Madame de Pompadour so he could say he had slept with Madame de Pompadour and she was a real bitch. The anger this inspired in the real Madame de Pompadour helped contribute to France turning against its former ally, Prussia, in the Diplomatic Revolution of 1756 and the subsequent conflict known as the Seven Years War. This may have been the source of Voltaire's comment: *"All the reasoning of men is not worth the sentiment of one woman."*

When Madame de Pompadour died in 1764, it is said Louis shed exactly two tears.

A brief history of women's body image and standards of beauty as defined by society

There is evidence of a biological standard of beauty, defined primarily by the ability to bear and nourish healthy children, although that standard has much wider parameters than cultures generally allow and can largely be summarized by the maxim: useful is beautiful.

Our earliest bits of evidence of standards of beauty are prehistoric figurines found throughout the Mediterranean and Europe and commonly referred to as "Fat Venuses". These small Paleolithic statuettes, probably don't represent primitive man's ideal of woman, but they suggest that more curvy or full-bodied

women were preferred. If the Venus of Willendorf (below), which is only four inches tall, were to scale, her bust-waist-hips measurements would be 96"-89"-96".

This makes sense when one considers that women, having more body fat than men, often had to nourish their young and stay alive for extended periods of time without food during the Ice Ages when winters were especially harsh, Presumably, the women who survived and had children that survived were typically large-breasted, making large breasts evolutionary winners.

By comparison, a woman with Barbie doll proportions would have some serious problems. Her 16-inch waist would also be four inches thinner than her head, leaving room for only half a liver and a few inches of intestine. Like her fragile 3.5 inch wrists, her 6-inch ankles would make supporting her body - despite so much of it missing - entirely impossible, requiring her to walk on all fours.

However, beauty has always been as much a matter of cultural preference as biology, and those preferences have changed at a somewhat dizzying pace. Sometimes beauty standards have even defied what was biologically useful, such as bound feet in traditional China, which rendered their victims virtually immobile. Generally, one can say the more affluent a society, or part of a society, has been, the more likely one would see diversions from what nature had intended, since “trophy wives” with no real needs for survival skills have been a luxury only the rich could afford. Thus as Europe’s economy recovered after 1400, wide swings in beauty standards took place more often from one era to the next.

Catherine de Medici, known as the fashion dictator of the 16th century, recommended an ideal waist size of 13 inches. By this time, she

could demand such crazy ideals because corsets had become the rage.

Between the 1500s and 1900s, women’s breasts went through radical mutations in fullness, flatness, position and cleavage. Eighteenth century Europe, in particular, switched breast vogues with wild abandon. However, women, armed with whalebone, iron and padding, tried their hardest to fulfill fad ideals.

The early corset ended just below the bust, pushing breasts up. The added lift was not enough for some, however. Toward the end of the 1700s, an early version of the Miracle Bra pushed the bust high — sometimes near the chin. Later, corsets would flatten breasts by squeezing the upper body. While made primarily of cloth, whalebone and metal, one was even made entirely of metal — the “coat-of-armor” corset.

Big hair is back. Nothing seemed to define fashion more than Big Hair during the Enlightenment. In England, this was largely a reaction against the Puritan style of women keeping their hair covered during the repressive era of Cromwellian rule. Much of this goes back to medieval Europe when it was customary for women to keep their hair covered as a matter of modesty. Even now, the expression “let one’s hair down” implies cutting loose from normal modest standards of behavior. Similarly, the continued use of veils by some brides reflects our culture’s long-standing concern with protecting women’s virtue.

During the Enlightenment, elaborate hairstyles were definitely in vogue, with women trying to outdo each other in magnificence as parodied in the picture below. Some women’s hair would be piled so high that they refused to go out on ballroom floors out of fear it would get caught in

the chandeliers and burn down. One German visitor remarked that a French woman's face was halfway between her toes and the top of her hair. In addition, women would incorporate various objects, such as birdcages with live birds, into their hairdos. For a while a model warship to commemorate a French naval victory was a fashionable hair accessory.

Note the men with big hair as well. In America, such dandies were referred to as *mararonis*, thus the line from *Yankee Doodle*

In the later 1700s, the trend swung back to simpler styles to keep in step with the Enlightenment's move to a more natural values as epitomized by Neo-classical and Romanticist art, then starting to become popular. Marie Antoinette, who was accused of over-extravagance, was actually an example of this more modest trend, her hair being toned down in portraits right before the French Revolution.

For a brief time during the French Revolution and Napoleonic era (c.1789-1815), women got a reprieve from the corset, as the tighter more restrictive fashions of the Old Regime were replaced by the looser, simpler, and "revolutionary" neo-classical style much as older political and social conventions were replaced. Women during this period were also more politically active, some of them expecting more rights, as reflected in Mary Wollstonecraft's "The Vindication of the Rights of Women."

However, the militaristic culture of the Napoleonic era and the conservative backlash against the Revolution after his fall led to a similar fashion backlash. More specifically, corsets made a comeback, along with bustles to accentuate the backside. Thus the nineteenth century was once again a period of lower status, not to mention difficult breathing, for women.

Young girls were sometimes forced to wear corsets, and those who complained were scolded. Besides, after a few weeks, pains (or all sensation) in the ribs and organs typically disappeared. Corsets eventually became controversial for health reasons, including fainting and muscle atrophy. Many women, however, defended corsets:

"(If) the various organs are prevented from taking certain form or direction, they will accommodate themselves to any other with perfect ease," said one woman in a letter to *Queen*, an 18th-century magazine.

After centuries of constrictive fashion, however, women in the 20th century began to choose comfort over the agony of 13-inch waists and bust pinchers. The flappers of the 1920s shocked their mothers by showing their natural shapes, while Coco Chanel (below) introduced clothing that felt as good as it looked.

For whatever reasons, along with the women's vote came shorter hairstyles and preference for smaller busts, causing critics to complain of the increasingly blurred distinction between men and women.

In the 1940s, the fuller figure came back into vogue, as seen in the pinup art popular with GI's during World War II. Marilyn Monroe, the sex symbol of the 1950s, had curves that were a far cry from the "thin is in" fashion of the 1920s.

The current ultra-thin ideal can largely be traced to Twiggy, the first “super-model”, a classic example of the media catering to the youth culture of the 1960s. Since then, women have been starving themselves in pursuit of ideals that for most are impossible to attain.

The Languages of Flowers and Fans

Say it with flowers, but know what you're saying. But just what are you saying when you give that special someone flowers? Following is a key to the symbolism represented by various flowers and colors of flowers.

- Yellow indicated disdainful love or infidelity.
 - Red represented passionate love or shame.
 - Green symbolized hope.
 - Blue stood for heaven.
 - Purple indicated power or royalty.
-
- Primrose, which blooms suddenly and in unexpected places, symbolized first love.
 - Roses were associated with love, but also beauty, heartbreak, joy, humility, etc.
 - Forget-me-nots were associated with true love from the story of a lover who falls in a river while picking some pretty blue flowers, and as he is swept away, calls " ...never forget me!"
 - Crocuses, in antiquity stood for passionate love, and in 1700s represented carefree youth.
 - Narcissus was associated with egoism, conceit, and not being able to love others from the Greek myth of Narcissus and Echo
 - Passionflower was associated with faith, religious superstition, susceptibility, or token of remembrance since it resembles

Christ's crown of thorns and nails.

The language of the fan. To a large extent, the fan was the 18th century equivalent of the cell phone, “texting” messages across a ballroom floor to one’s secret boyfriend. Below is an introduction to “fan speak”:

- 1) *Fan near the heart: You’ve won my love.*
- 2) *Closed fan touching the right eye: When may I see you?*
- 3) *The number of sticks shown answers: At what hour?*
- 4) *Threatening movements with a fan closed: Don't be so imprudent*
- 5) *Half-opened fan pressed to the lips: You may kiss me*
- 6) *Hands clasped together holding an open fan: Forgive me*
- 7) *Covering left ear with open fan: Do not betray our secret*
- 8) *Hiding the eyes behind an open fan: I love you*
- 9) *Shutting fully opened fan slowly: I promise to marry you*
- 10) *Drawing the fan across the eyes: I am sorry*
- 11) *Touching finger to tip of the fan: I wish to speak to you*
- 12) *Letting the fan rest on the right cheek: Yes*
- 13) *Letting the fan rest on the left cheek: No*
- 14) *Opening and closing the fan several times: You are cruel*
- 15) *Dropping the fan: We will be friends*
- 16) *Fanning slowly: I am married*
- 17) *Fanning quickly: I am engaged*
- 18) *Putting the fan handle to the lips: Kiss me*
- 19) *Opening a fan wide: Wait for me*
- 20) *Fan placed behind the head: Do not forget me*
- 21) *Fan placed behind the head with finger: Goodbye*
- 22) *Fan in right hand in front of face: Follow me*
- 23) *Fan in left hand in front of face: I am desirous of your acquaintance*
- 24) *Fan held over left ear: I wish to get rid of you*
- 25) *Fan drawn across forehead: You’ve changed*
- 26) *Twirling fan in left hand: We’re being watched*
- 27) *Twirling the fan in the right hand: I love another*
- 28) *Open fan in the left hand: Come talk to me*
- 29) *Drawing the fan through the hand: I hate you!*
- 30) *Drawing the fan across the cheek: I love you*
- 31) *Presenting the fan shut: Do you love me?*

THE RISE OF THE MODERN STATE IN ENLIGHTENMENT EUROPE

"It appears that God has created me, pack horses, Doric columns, and us kings generally to carry the burdens of the world in order that others might enjoy its fruits."-- Frederick II, "the Great", of Prussia

Introduction. Just as the Enlightenment *philosophes* saw a rational plan in the laws of nature and the universe, they also influenced rulers in building their states along rational lines. For the first time in European history, there was a general realization of the relationship between economic, administrative, diplomatic, and military factors in state building. Despite their vast differences, there was a general trend in both Eastern and Western Europe toward more tightly run bureaucratic states. Public works projects, such as roads, bridges, dams, and canals, multiplied in the hope of building the economy of the mercantilist state. New government departments also appeared in such areas as postal services, forests, agriculture, and livestock raising. States also took censuses and kept statistics in order to plan out policies better.

In order to understand the evolution of the modern state, one needs to understand that the feudal state was *patrimonial*. In other words, the kingdom was the patrimony (hereditary property) of a dynasty. Likewise, the various judicial and administrative offices that ran the kingdom at the provincial and local levels were the patrimonies of privileged families. The modern concept of kings and officials who were accountable for their actions and responsible for the welfare of their subjects was much weaker in the old feudal state, making the state more a federation of separate principalities that, in theory, owed allegiance to a common monarch. In the High Middle Ages, this concept of one monarch, among other things, provided at least some degree of order, helping lead to the rise of towns and feudal monarchies which supported each other and increased each other's strength. Over the years, a common language and culture along with the spread of nationalism after the French Revolution united many of these states into what we would call nations. The feedback between the rise of towns and kings produced two lines of

development that would help each other in the rise of the modern state.

First, the rise of towns and a money economy helped provide the basis for the Italian Renaissance and Protestant Reformation. Calvinism, in particular, saw all believers as equal in God's eyes, which discredited Divine Right of Kings, helped justify religious/political revolution, and lay the foundations for modern democracy in the Dutch Revolt and English Revolution. By the late 1600's the religious element was fading from theories of revolution. Such political writings as John Locke's *The Social Contract* pushed the idea of the ruler being responsible for the welfare of his subjects on legalistic rather than religious grounds. Secondly, kings were building strong nation-states that, by the 1600's, were assuming greater control over all aspects of the state. For example, the economic theory of mercantilism spurred rulers to work to develop the resources of their kingdoms.

Together these led to a growing realization of the interrelationships between administrative, economic, and political factors in the overall welfare of the state. As a result, more and more royal officials were trained professionals. They had to take competitive exams to gain their positions and did their jobs efficiently and impartially. Kings and their officials also paid more attention to building and maintaining public works such as roads, bridges, and canals to improve the economy. While the purpose of these reforms was to increase the tax base for the kings, they also benefited their subjects. Higher standards of administration made people see their officials as a bureaucracy of service rather than one of privilege. And since they were the king's men carrying out his will, people also saw their king as a public servant working for *their* benefit rather than as privileged owners of the state. Over time, this became the public expectation, which still predominates thinking about the state today. Frederick the Great's quotation at the top of the reading best represents this idea of the king as public servant. As a result, in the 1700's the term absolute monarchy gave way to the term "enlightened despot", a monarch who ruled according to enlightened principles rather than the divine right of kings.

The eighteenth century state still had problems. For one thing, it had a modern political administration

superimposed upon a feudal social order. Nobles were still the privileged social class, holding most of the important administrative and military positions. Peasants in Central and Eastern Europe were still downtrodden serfs. Even French peasants, who were free by previous standards, still were burdened with many feudal obligations.

In spite of this, the centralized states emerging in the Enlightenment were important in the evolution of our own modern states in two ways. First of all, the emergence of a professional bureaucracy, chosen largely for merit, not money or birth, provided the state with a modern administrative structure that continues today. Second, the idea of the rulers and officials being servants, not owners, of the state was central to the revolutionary ideas that swept Europe starting with the French Revolution in 1789. A closer look at several of the major states of eighteenth century Europe will give a better idea of their accomplishments and limitations.

France under Louis XV may at first glance have seemed like a strongly unified state. But it had serious problems at the center of government. First of all, the court at Versailles with its petty intrigues stifled the work of most capable officials. Instead of tending to their appointed duties, officials spent more time defending their positions at court. Under Louis XV there were 18 foreign secretaries and 14 controller generals, most of them eventually ruined by palace intrigue. Their average terms of office were between two and three years. At the center of this was the king, Louis, who was a somewhat intelligent, but weak-willed and disinterested man who let others run the government for him.

Another problem for the central government was the intense competition between the council of state (with whom the king made laws and policy) and the various ministers (justice, finance, war, navy, foreign affairs, and the king's household) who carried out, but often modified the king's policies. Given what court intrigue did to many of the ministers, one can imagine the confusion and lack of direction in France's central government.

By contrast, the provincial government was fairly efficient. The main figures here were the *intendants* that ran the 32 *generalites* (provinces) set up by Richelieu some 100 years before. He was in charge

of tax collection, justice, and policing his province, and he had a fairly free hand to carry out these duties as he saw fit. The intendant was the king's agent in the province and was the man most Frenchmen saw as representing royal authority. He also represented the interests of the people to the central government, and the king's ministers and councilors generally respected his opinion. In contrast to the unfortunate officials close to Versailles, the intendants generally kept their positions for decades, which allowed them to know their territories and peoples more thoroughly and better rule them. The intendants were often criticized for being too powerful and corrupt. There certainly was some corruption, but in general, the intendants represented efficient and conscientious government. Unfortunately, nobles, anxious to preserve and regain their ancient prestige, even took over more and more intendant positions as the 1700's progressed.

The intendants needed help at the local level. These lower level officials fell into three categories. The first category consisted of feudal officials who had bought or inherited their positions. Such men had little training or care for their work and were a burden to the intendants that were stuck with them. Next, there were subdelegates, who were poorly paid, poorly trained, and also of little use. Finally, there were what we might call true civil servants. These were specialists (engineers, architects, physicians, etc.) who had to take competitive tests to gain their positions. These were the men who usually carried out the directives of the intendants and kept the French state running. It was these officials who would survive the French Revolution and become the nucleus of the modern French civil service.

Maria Theresa of Austria

The Hapsburg Empire may have been an absolute monarchy, but it was a far cry from being a unified state. The War of the Austrian Succession (1740-48) especially pointed out the need to organize an administration such as Richelieu and Frederick

William the Great Elector had done for their respective states a century earlier. The central government in Vienna had a number of governing bodies whose functions overlapped, which led to great confusion. A full one-third or more of all taxes collected never made it to Vienna, so no effective budget could be made. Local government consisted of noble estates (assemblies) that granted or refused the central government its taxes. Nobles in Hungary owned 80% of the land and paid no taxes, leaving the full tax burden to the peasants. The nobles also maintained jurisdiction over the peasants on their lands. It was this mess that the Austrian minister, Count Haugwitz, set out to clean up. He did it at the central, provincial, and local levels. The central government was streamlined into five ministries: foreign affairs, commerce, war, justice, and internal affairs. Typical of the prevailing mercantilist philosophy of the day, the minister of finance was deemed most important in both France and Austria.

At the provincial level, an administrative board known as the *gubernium* largely replaced the power of the noble estates. In 1748, after the disasters of the War of the Austrian Succession, the estates recognized the need to reform the state and granted ten years worth of taxes to the central government. This meant that the empress could rule without the estates for the next decade. As their power withered, that of the *gubernium* increased. Thus the feudal estates were gradually replaced by a more modern system. Another important principle that took over here was that of the separation of powers within a government, specifically between the courts and the executive/legislative branches. This principle was pushed by the French *philosophe*, Montesquieu, and has remained an important part of the modern state down to this day.

At the local level, a Hapsburg official, the *kreishauptmann*, interfered more and more in the affairs traditionally left to the noble estates. The more such officials became involved in the daily affairs of the peasants, the more concerned they and the Hapsburgs were for their welfare and their ability to pay taxes. Therefore, the *kreishauptmann* became the virtual champion of the peasants against the nobles, preventing them from evicting peasants and taking their lands or forcing them to do extra servile labor.

Maria Theresa's government also effected a major fiscal reform to raise revenue. Even nobles and clergy had to pay regular property and income taxes. This distributed the tax load more evenly, but there were still gross inequities. The average peasant still paid twice the taxes that a noble paid. And Bohemia was liable for twice the taxes that Hungary was. Still, her reforms were a giant step forward for the Austrian Empire, and her system remained the basis for Hapsburg administration to the end of the empire in 1918.

Maria Theresa's son, Joseph II (above), carried the spirit of enlightened rule even further than she had. He was an enlightened ruler who was determined to use his power to make his people live according to enlightened principles whether they liked it or not. Joseph's reforms cut across the whole spectrum of the Hapsburg state and society. In the judicial realm, he had the laws codified, tried to get speedier and fairer trials presided over by trained judges, and outlawed torture, mutilation, and the death penalty. He ordered toleration for both Protestants and Jews and legalized interfaith marriages. Along the same lines, he relaxed censorship, restricting it only to works of pornography, atheism, and what he deemed superstition.

Joseph was a devout Catholic, but saw the Church as a virtual department of state that needed some house cleaning. Therefore, in 1781 he closed down many monasteries or converted them into hospitals and orphanages. He also required a loyalty oath from the clergy to ensure tighter control of the Church. He controlled and encouraged education, especially for the purpose of producing trained civil servants. Through a combination of incentives for families who sent their sons to school and punishments for those who did not, Austria under Joseph had a higher percentage of children in school than any other state in Europe.

Joseph's reforms extended to trying to make his subjects' lives easier. Although he failed to abolish serfdom, he did get the number of days per week that peasants had to work for their lords reduced from four to three and evened out the tax burden

paid by peasants and nobles. He tried to encourage trade and industry through high protective tariffs, tax relief, subsidies, loans, and the building of roads and canals. He rewarded immigrants, but severely punished those trying to emigrate from his empire. Sometimes, his decrees could interfere with the minutest aspects of people's lives, such as forbidding them to drink the muddy water of the Danube or to eat gingerbread and encouraging peasants to mix vinegar with their water.

By his death, Joseph had increased his empire's revenues from 66 million to 87 million florins, while virtually tripling the size of his army. Unfortunately, no amount of reform probably could have solved the Empire's most serious problem: the large number of different nationalities and cultures forcibly held under Hapsburg rule. Although there were attempts to impose German language and culture throughout the Empire, in the long run, the Hapsburg Empire was a virtual time bomb of nationalities waiting to explode and fragment into different states.

Prussia was the state that most people saw as the epitome of the enlightened despotate. To a large extent, poverty built the Prussian state of the 1700's. It created a tightly run and loyal officer class by forcing impoverished nobles into service to the state. It also forced Prussia's rulers to adopt the tight-fisted economic measures that became the basis of Prussian discipline and regimentation into this century.

At the center of this was Frederick II (above) himself, whose incredible energy, drive, and intelligence were more than equal to what all the ministers and rulers of any other state in Europe were capable of. Frederick clearly saw the interdependence of foreign, domestic, military, and financial affairs and was determined to direct all these affairs personally. Therefore, he served as his own foreign minister, finance minister, and general staff. (He even scouted enemy positions by himself, much to the worry of his officers.)

Frederick's workday started at 4 AM and extended to 10 PM. The vast body of work and responsibilities he undertook required an incredibly organized schedule and work routine. His civil servants in Berlin sent him details and data on specific matters, and he sent back orders he expected them to carry out punctually. His court at Potsdam had neither family, court etiquette, religious holidays, nor other distractions to impair the government's efficiency. The court and government resembled a barrack and were run with military precision. If any one man gave us the idea of the state serving the people rather than the other way around, it was Frederick the Great.

Frederick had little faith in either his troops or bureaucracy and subjected them to severe surveillance and discipline to make sure they did their jobs. Royal agents, known as *fiscals*, combined the duties of spies and prosecuting attorneys to keep the bureaucrats in line. Any examples of corruption led to immediate dismissal. Civil servants had virtually no civil rights (including that of a trial) and have been described as the "galley slaves" of the state. Even with the fiscals, Frederick felt he needed better information about his government and kingdom. Therefore, he had subordinates report to him about their superiors. He also made an annual tour of the kingdom from May to August, personally examining officials, interviewing private citizens, inspecting local conditions, and gathering immense amounts of information. There were few things of importance that escaped Frederick's notice for long.

Unlike the rest of Europe, where most public offices were either bought or inherited, Prussia required all of its civil servants to earn their positions by passing a civil service exam. Most candidates had a college education in jurisprudence and government management. All of them, regardless of class, also had to spend one to two years on a royal farm to familiarize themselves with the various aspects of agriculture, in particular the new scientific agricultural techniques being developed and the issues of lord-serf relations.

At the provincial level, there were 15 provincial chambers, each with 15 to 20 members. Since the members were responsible for each other's actions, there was little corruption at this level. The provincial chambers had two main duties: to collect

taxes; and stimulate the economy to raise the tax base. In true mercantilist spirit, they had sandy wastes reclaimed, swamps drained, and new settlements founded. They went to England and Holland to study commercial and agricultural methods there, sought out markets for Prussian goods, and arrested any vagabonds they found, since laziness and indolence were public offenses in Prussia.

At the local level there were the *steurrat* and *landrat*, who administered towns and rural affairs respectively. The *steurrat* ruled from 6 to 10 towns, and left them little in the way of home rule. In addition to collecting taxes, he fixed food prices, enforced government decrees, regulated the guilds, and kept the garrison properly housed. The *landrat* had much the same duties in the countryside, but was not so closely supervised by the central government, largely because the king had too little money to closely control the *Junkers* (nobles). The *landrat* was always a local noble and estate owner and was elected to his position by his fellow *Junkers* as often as he was appointed by the king. The *landrat* exercised all the functions of local government: tax collecting, administering justice, maintaining public order, and conscripting recruits for the army. As long as he did his job and did not abuse the peasants too severely, the central government largely left him alone.

Russia. Catherine the Great of Russia (above) also strived to be an enlightened despot, at least in appearance. However, Russia was too big and far behind the West to transform it into an enlightened society overnight. The court, to be sure, reflected the fashions and manners of courts in the rest of Europe. However, this was a mere facade to mask the still medieval nature of the rest of society in the countryside. Symbolizing this facade was the series of fake villages stocked with healthy prosperous looking peasants that Catherine's prime minister, Potemkin, set up to fool Catherine into thinking her realm was indeed on a par with the West. Unfortunately for Russia, parity with the West was

far from the case, and Russia would pay a heavy price for its backwardness in the years to come.

Frederick the Great's Daily Routine

Frederick's day started at 4AM, although he hated it. If he wouldn't wake up, he told his servants to throw a cloth soaked in cold water on his head. If, out of pity, they let him sleep, he would put them in the army. Frederick, like his father, suffered from a chronic stomach illness and was in constant pain, but hardly mentioned it. He also had little patience with others complaining of sickness, since he drove himself so relentlessly. His court at Potsdam had neither family, court etiquette, religious holidays, nor other distractions to impair the government's efficiency. The court and government resembled a barrack and were run with military precision. Similarly, he had no time for fancy uniforms, usually being dressed in a dirty and shabby uniform. His one luxury was a collection of 1500 snuffboxes, all of them full, which proved a torture for the English ambassador who was allergic to snuff and sneezed constantly.

Once out of bed, Frederick composed music while his hair was curled. He also practiced the flute at least four times a day, claiming that was when political ideas came to him. Frederick was an accomplished composer, whose compositions are still performed and recorded.

After that he examined his mail. The king had a vast knowledge of coats of arms, so he could save time by throwing the unopened letters of people who bored him into the fire. Personal friends' letters he answered personally, the rest going into one of three baskets: granted, refused, or consult further on it. At breakfast, the royal secretary came for the letters, for each of which Frederick gave a summarized answer in one sentence. There were three secretaries who had to have all the letters ready by 4PM.

At 10AM the king either directed military exercises, wrote personal letters, or walked in his garden with a book. His constant companions were two or three Italian greyhounds, who even slept on his bed with him. It was one of these dogs he named after the French king's mistress, Madame de Pompadour, arousing so much ire in the woman that it helped lead to the Seven Years War.

[Back to flowchart](#)

The king would then dine at noon with various writers, wits, and soldiers. Despite his stomach condition, he liked highly spiced food and drank lots of coffee and champagne. This would last until 3 PM, unless it was sunny (which he loved), in which case he would bolt his food so he could go for his afternoon walk. Frederick's walks were not popular with those who attended since he liked to amuse himself at their expense.

From 3PM to 10PM, Frederick was engaged in administrative work. After that came supper and then a concert. Besides being a composer, Frederick was also a good flautist, but had erratic timing, making it hard to accompany him. One of his personal highlights was when the composer Johann Sebastian Bach visited him.

Frederick and Voltaire. For a brief time, Voltaire stayed with Frederick at his Sans Souci palace (below). However the huge intellects and egos of the two men led to a falling out. Frederick claimed he had squeezed the juice from the orange and thrown away the peel, apparently meaning he got all the wisdom he needed from Voltaire before kicking him out. Voltaire later got his revenge in *Candide* by describing the abuses of the Prussian army, thinly disguised as the Bulgarian army.

THE FLOW OF ENLIGHTENMENT IDEAS

Introduction. Although the Enlightenment spawned ideas on a wide range of subjects from the sciences to religion and the state, it is important to see how all these ideas occurred in something of a sequence that fit together in a fairly unified way. This is especially crucial for us today, since we largely isolate the various academic disciplines from one another rather than see how they relate to one another. Perhaps the twenty-first century will see such a synthesis take place.

Starting with the scientific revolution, we need to go back to the Renaissance with new findings in astronomy and physiology that seemed to contradict old theories, especially those of Aristotle. At first these led to explanations that were still framed in the context of old theories, especially if another ancient authority, such as Plato or Pythagoras, could be used to back it up. However, these natural philosophers, as they were called, kept finding more and more evidence that seemed to contradict the old theories until they had to come up with new syntheses and theories of their own. We have looked at two of these processes in particular: Newton's synthesis in physics and astronomy, and Harvey's synthesis concerning the circulatory system.

In addition to creating the scientific basis for the industrial revolution in the 1800s, they also opened the way for new ideas outside of science. Key to this was the fact that the scientific revolution had discredited the Church and raised the belief in humanity's ability to reason. For some, this led to the philosophy of Deism, the belief that God exists but is not actively involved with this world, leading to the conclusion that humans can and must solve their own social, economic, and political problems. Out of this came a new branch of study, the social sciences.

In the realm of political science, a whole new body of ideas emerged concerning the state and our relationship to it: the belief in civil liberties for everyone (or at least all men), democracy, and the separation of powers within a government. Central to all of these was the idea that the state, instead of being a divinely ordained absolute monarchy, is an implied contract between ruler and subjects, each with mutual rights and obligations. In economics, the prevailing idea, as expressed in Adam Smith's *Wealth of Nations*, was free trade capitalism. In psychology there was the Blank Slate theory that our characters are purely the result of our

environment and experiences. This would spark a nature versus nurture debate that still goes on.

The new theories about the state had a very real impact on many Enlightenment rulers, such as Frederick the Great of Prussia and Joseph II of Austria, who were increasingly aware of the impact of their administrative, economic, and political policies on their own power. Therefore, following the prevailing philosophy of mercantilism, they started establishing better civil services by choosing more of their officials based on merit, sometimes determined by civil service exams. They also created more public works (roads, bridges, canals, etc.) to improve the economy and their tax base. Sometimes these mercantilist policies were too heavy-handed in how they were carried out, but in many cases they benefited society. Unfortunately, at this time, trying to impose these reforms on a society that still had many feudal features also impeded progress: such things as tax exempt nobles, hereditary offices (including the monarchy), and extra feudal dues burdening the peasants.

Of course, these reforms were done in most cases for the benefit of the king, but they also often benefited society as a whole, giving rise to the idea that the state was working for the benefit of the people instead of the other way around. Out of that idea came rising expectations for more benefits from the state. People even started feeling that when those expectations were not met, they had the right to rebel. That is exactly what would happen in France in 1789.

BALANCE OF POWER POLITICS IN THE AGE OF REASON (1715-1789)

"Dogs! Do you want to live forever?"-- Frederick the Great to his troops in the heat of battle.

Introduction. The period from 1715-1789 was one of transition between the religious wars of the 1500's and early 1600's and the wars of nationalism and democracy starting with the French Revolution. This was also the era of *balance of power politics* where Europe operated as an integrated system, so that one state's actions would trigger reactions from all the other states. As a result, it was hard for one state to gain an overwhelming position in Europe without everyone else, in particular Britain, ganging up to restore the balance. Finally, it was a period of intense competition between European states, a competition that would launch Europe into the two bloodiest centuries in all human history.

Diplomatic maneuvering (1715-1740). The death of Louis XIV in 1715 ended the bloodiest and most exhausting period of warfare up to that point in European history. The scale of bloodshed and expenditure was so massive that it would take several years before Europe would be ready for another major war. However, mutual distrust kept the various powers eyeing each other suspiciously and constantly maneuvering to maintain a stable or superior position in case war did break out. Spain and Austria conspired to take Gibraltar from England, causing Britain and France to ally to stop this plot. Britain, Austria, and Holland signed the Barrier Treaty in 1718, by which Austria got the Spanish Netherlands (modern Belgium) in return for manning the barrier fortresses against any future French aggression. Because of this maneuvering (or maybe in spite of it) peace ruled over most of Europe for nearly two decades.

The first major disturbance was the War of the Polish Succession (1733-39). The death of the Polish king led to rival claims by French and Austrian candidates, and these claims led to war. Austria and its ally, Russia, being closer to Poland, emerged victorious over France and Spain. The only compensation was that the Spanish Bourbons got control of Southern Italy and Sicily. The War of Polish Succession symbolized the growing importance of Eastern and Central Europe in diplomatic affairs. In fact, events surrounding two

of these states, Prussia and Austria, would dominate European affairs for much of the eighteenth century.

Frederick William I of Prussia (1713-40)

"No reasoning. Obey orders"
"Salvation belongs to the lord. Everything else is my business."
--Frederick William I of Prussia

Since 1640, Prussia had been quietly but steadily gaining strength. Under Frederick William the Great Elector (1640-88) and his grandson, Frederick William I (1713-40), Prussia evolved from a small war ravaged principality to a highly centralized independent kingdom. Its two pillars of strength were its highly disciplined and efficient army and bureaucracy. Prussia was a poor country, and Frederick William I did a masterful job of making the most from the least through a combination of intense economizing and severe discipline and regimentation of virtually every aspect of Prussian society. History has seen few skinflints of Frederick William I's caliber. He cut his bureaucracy in half, cut the salaries of the remaining civil servants in half, dismissed most of his palace staff, sold much of his furniture and crown jewels, and even forcibly put tramps to work. But he expected no more of his subjects than he did of himself as the first servant of the state, probably a legacy of his Calvinist upbringing.

Frederick William's main expense was the army, which is not surprising when one considers Prussia was surrounded by Austria, Russia, and France, all with large armies of at least 90,000 men. By his death in 1740, Prussia's army numbered some 80,000 men. Frederick William's pride and joy was his regiment of grenadiers, all of them over six feet tall (remarkably tall back then). His friends would give him any six-foot tall recruits they could find, while he kidnapped most of the rest. In spite of this military buildup, Frederick William I followed a peaceful foreign policy and left his son, Frederick II, both a large army and full treasury.

Prussian military discipline: flogging (top) & running the gauntlet. The Prussian army was notorious for its harsh discipline. While it was the most efficient army in Europe, it also had the highest desertion rate.

Frederick-William's son, Frederick, presents a fascinating contrast to his father. While the old king detested anything that suggested France and culture, his son treasured those very things. (To drive this point home, Frederick-William would dress condemned criminals in French clothes.) This made Frederick's childhood very difficult. On the one hand, he was required to wear a military uniform and live the life of an officer. On the other hand, he took every possible chance to learn music, speak French, and curl his hair and dress in French fashion, having to post guards to warn him of his father's approach so he could do a quick costume change..

This infuriated the king who often beat his son in fits of rage. Frederick-William would beat his son in fits of rage. Once he threw a dinner plate at him. On another occasion, he tried to strangle Frederick with a window shade cord and was only stopped by his servants. The king even told his son that if his (Frederick-William's) father had treated him as he treated Frederick, he would at least have been man enough to commit suicide.

The king's chronic illness did not help his temper. Neither did Frederick's tendency to tease his father and see how far he could push him. At one point, Frederick tried to escape from Prussia, was captured, court-martialed, condemned to death, and finally released after a lengthy imprisonment. It is a wonder that one of them did not kill the other. However, when Frederick William I died, father and son had been reconciled. It is interesting to see how similar to and different from his father Frederick II would turn out to be as king.

The War of the Austrian Succession (1740-48).

The French victory at Fontenoy (1744) during the War of the Austrian Succession

Frederick's eyes were turned toward the rich Hapsburg province of Silesia. The timing could not have been better for Prussia. Austria was in pitiful shape to fight a war, having just lost a disastrous struggle with the Ottoman Turks. Its generals and ministers were old men past their prime, while the administration was full of corruption and confusion. And to make matters worse, the old emperor, Charles VI had just died, leaving a young woman, Maria Theresa, to succeed him. Charles had gotten most of Europe's rulers to sign the *Pragmatic Sanction*, a document recognizing his daughter as the legal heiress. But many questioned the legality of Maria and her husband taking the throne, and set up the elector of Bavaria as an alternate candidate. This was the situation for the unfortunate Maria Theresa (below) when Frederick invaded Silesia. Just to add to her difficulties, she was pregnant at the time.

However, as Frederick William I had warned the young Frederick, wars were generally much harder to end than start, and this one did not stop at Silesia. France, Spain, Bavaria, and Saxony all joined Prussia, hoping to pick Austria clean. Austria's ally, Russia, was neutralized when Sweden joined the other side against it and Austria. Only Britain, which generally tried to maintain the balance of power to protect its trade, backed Austria. Unfortunately for Austria, Britain had a small army

and was mainly concerned with defending George II's principality of Hanover from neighboring Prussia. As if Frederick William I had been a prophet, a simple move into Silesia had triggered what amounted to a global conflict, with fighting in India and the American colonies as well as Europe.

Mollwitz, the first battle of the War of the Austrian Succession, was a bit embarrassing for Frederick. His army won, but not until he had fled prematurely from the field. After that, however, he showed a flair for brilliant generalship and decisive movements that were unequalled until Napoleon some fifty years later. His victory at Mollwitz won him Lower Silesia and left Maria Theresa, who had just given birth to a son, somewhat destitute. However, the young queen showed she had some spirit and fight of her own. She rallied the Hungarian nobles to her side, raised an army, and secured an alliance with England. Next, she made a secret truce with Frederick, giving him Lower Silesia if he would drop out of the war. Then, she surprised everyone by invading Bavaria and throwing her enemies, now without Frederick, off balance.

With Austria's fortunes restored, the war still dragged on for eight years. Frederick would occasionally re-enter the war, revive his allies with his brilliant leadership, and then be bought off with more of Silesia. At last, bloodshed and exhaustion led to the Peace of Aix-la-Chapelle in 1748. Frederick kept Silesia, while Maria Theresa had survived and saved the rest of her empire. However, she was burning for revenge against Frederick.

The "Diplomatic Revolution" of 1756. The first thing Maria Theresa needed to do was reorganize the Hapsburg Empire. Therefore, she centralized the government, reorganized finances, and built up the army. Next, she set about looking for allies against Frederick. First, she renewed her alliance with Russia, thus securing her eastern flank and endangering Prussia's at the same time.

With the Austro-Russian alliance already threatening Frederick with a two front war, he saw his choice for allies lay between France and Britain. France, his current ally, was slow-moving and reluctant to fight another war. England, on the other hand, already threatened his western border

and had signed a treaty agreeing to pay for Russian armies. Therefore, by secretly allying with Britain, Frederick felt he was neutralizing the threats to both his western and eastern borders, since Britain would now guard, not threaten, his western borders, and subsidize his armies, not Russia's.

Frederick felt that Russia could not fight without British money and that France would not mind his alliance with Britain to keep the balance of power in Germany. He was wrong on both accounts. Louis XV was furious about Frederick making a treaty with Britain without consulting him. As a result, France allied with Austria and agreed to finance Russia's war effort. This ended 250 years of hostility between France and Austria, bringing about a virtual diplomatic revolution in how the powers in Europe were aligned. Frederick, finding himself surrounded by enemies, took the initiative and invaded Saxony. The Seven Years War had begun. Now it was Frederick's turn to prove himself in the face of overwhelming odds.

Prussia' trial by fire: the Seven Years

The Seven Years War (1756-63) was actually two conflicts combined into one giant war. In addition to the continental war of Prussia against Austria, Russia, and France, there was also the struggle for colonial empire between Britain and France. The war thus assumed global dimensions, extending from Europe to North America, the West Indies, Africa, India, and the Philippines.

Prussia's struggle was especially desperate. Frederick, facing a three front war, was forced to race from one frontier to the next to prevent his enemies from combining in overwhelming force. Even then, he still was always outnumbered. The war started with two disastrous defeats, and it looked like Prussia was finished. Then amazingly, Frederick came back to win two brilliant victories in rapid succession against France and Russia. Britain committed itself to guard Hanover and pay for Prussia's army, thus neutralizing the French war effort on the continent.

France against Britain

Now it came down to a duel against Austria and Russia. The war raged year after year and fell into vicious cycle where Frederick would clear one frontier of enemies. Meanwhile, another enemy would invade Prussia elsewhere, forcing Frederick to rush there to expel this new threat. However, this only exposed another frontier to invasion, and the cycle went on. Against such odds, Frederick lost as many battles as he won. However, his iron will and determination to save Prussia gave him the strength to bounce back, gather a new army, and drive back each new invasion. The Seven Years War became something of a patriotic struggle for the Prussian people, who were called on in greater numbers to defend their homeland. Junkers (nobles) only 14 or 15 years of age rushed to enlist, as did many peasants. The civil service carried on throughout much of the war without pay. The heroic example of Frederick inspired many Germans outside of Prussia to praise him as the first German hero within memory able to defeat French armies. Even French *philosophes* sang his praises.

Equally amazing was Prussia's resilience and ability to keep raising new armies with remarkable speed. This was the result of the system of creating a reserve of peasants who trained in the off-season and could replace casualties in the regular army as they occurred. To Frederick's enemies, it seemed he was raising armies out of the soil. In a manner of speaking, he was. It proved to be Prussia's salvation and would point to a new and much more destructive way to wage war.

But the grim business of war dragged on and on. From Frederick's point of view, this was a war of attrition and exhaustion. If he could hang on long enough and inflict enough casualties, his enemies would tire of the war and go home. As luck would have it, the Tsarina Elizabeth died in 1762. Her successor, Peter, was an ardent admirer of Frederick. Not only did he abandon Austria, but also he offered Russian troops to help Frederick. But Peter was soon murdered by his wife, Catherine, who ascended the throne and pulled Russia completely out of the war. This left only Austria and Prussia, who were both exhausted by the war.

Meanwhile, Britain and France were locked in a colonial struggle, which took place over control of North America (known as the French and Indian Wars), the West Indies, India, and slave stations on the African coast. In each case, British financial and naval superiority proved decisive, cutting French troops off from home support while bringing British colonial armies overwhelming reinforcements. The resulting British victories cut French colonial trade by nearly 90% while British foreign trade actually increased. This both deprived France of the means to carry on the colonial war and gave Britain added resources for it, which led to more British victories, more British money, and so on. Even Spain's entry into the war on France's side in 1762 made little difference. By this time, the British war machine was in high gear under the capable leadership of Prime Minister, William Pitt. Therefore, British forces easily crushed the Spanish and took Havana in Cuba and Manila in the Philippines.

By the end of 1762, both sides were ready for peace. The resulting Treaty of Paris in 1763 was a victory for Prussia and Britain. Prussia, while getting no new lands, kept Silesia and confirmed its position as a major power. Britain stripped France of Canada and most of its Indian possessions, and emerged as the dominant colonial power in the world. Although Russia gained no new lands, it emerged as an even greater European power.

The Partitions of Poland

The Treaty of Paris had effects in both Eastern and Western Europe. In the East, the emergence of Russia as a major power was a matter of concern to other European nations. The country directly in Russia's path of expansion was Poland. At one point, Poland had been a major power in its own right that had picked on the emerging Russian state. Now the tables were turned. Russia was a growing giant, and Poland was crumbling to pieces, largely because of a powerful nobility and weak elective monarchy. Frederick also had his eyes on Poland, in particular the lands cutting East Prussia off from the rest of his lands in Germany. Since Russia, Prussia, and Austria were still exhausted from the Seven Years War, they agreed to divide part of Poland peacefully among themselves in 1771. However, their greed was not satisfied, and there were two more such partitions in 1793 and 1795, which eliminated Poland from the map. Since that time until the collapse of the Warsaw Pact in 1989), Poland has mostly lived under the yoke of foreign (mainly Russian) domination.

The American Revolution. In the West, the last major event before the French Revolution was the American War for Independence (1775-83). For once, Britain, the big colonial power, found itself ganged up on by France, Spain, and Holland. This war had two important results in Europe. First, it left France bankrupt. Second, it established a democratic republic that many Frenchmen saw as an inspiration.

In both cases, the result would be revolution in France, and that would have global repercussions.

The Toll of War on Frederick

The Seven Years War took as heavy a toll on Frederick as anyone else. However, it was his iron determination to fight to the bitter end that kept Prussia going, inspired other Germans, and made Frederick a virtual legend in Germany.

Frederick compared himself to someone afflicted w/dropsy who "from day to day marks the progress of his disease, feels the cold messenger of death in his limbs & calculates in advance the moment when his heart, too, will die."

However, he was determined never to give in, even when urged to do so by the British:

"Never will I survive the moment in which I am forced to sign a dishonorable peace; no eloquence, no inducement can drive me to subscribe to my own disgrace. I will either bury myself beneath the ruins of my country, or, if this consolation is too sweet for the fate which persecutes me, I shall put an end to my misery when I can endure it no longer."

Other Fronts, Other Wars

The Seven Years War was in a very real sense, a global conflict, with fighting taking place in North America, Asia, off the coast of Africa, and on the high seas. Outside of Europe, most of the fighting was between France and England over their colonial empires.

In India, fighting took place between the British East Indies Company and French East India Company. The inhospitable climate and distance from Europe led to both sides recruiting native troops, known as *sepoys*, and training and arming them in European fashion. Although it was the French who pioneered this strategy, the British emerged victorious and drove the French from India. In coming years, the British East Indies Company would conquer and rule most of India until the British government took it over in 1857.

In North America, European linear tactics of were of little use against the hit and run warfare

the French and their Indian allies used. However, the British adapted to these tactics to win the war and would later apply these lessons to forming lines of skirmishers to disrupt their enemies in the Napoleonic Wars.

Myth of the Minutemen

While skirmishers had their value, they tended to be over-rated by the Americans who won their freedom from Britain. The first clash in the American Revolution took place at Lexington and Concord in 1775. The colonial militia pretty much held their own in this running skirmish, giving rise to the myth that the irregular tactics of the minutemen won the war. In reality, it took the Continental Army, a regular army trained largely by European officers, and foreign aid from France to win the war.

[Back to flowchart](#)

THE POTATO AND ITS IMPACT

While one can hardly wonder how peasants survived the depredations of invading armies throughout history, in Europe, part of the answer seems to lie with the lowly potato. The potato is not native to the Eastern Hemisphere and was first noticed by Pizarro's men when they were fighting in Peru. The potato was a staple of the Incas' diet and was what saved many of Pizarro's men from starving on their return trip to Spain. It thrives in the cool damp climate found in the Andes as well as in parts of north-western Europe and can provide from two to four times the calories per acre than grain crops.

Unfortunately, the potato initially met resistance in Europe, because it required more work (i.e., hoeing) than grain crops, and its appearance raised the fear that it could cause leprosy. Some rulers in Europe would actually eat potatoes in public to show that it wasn't linked to such an affliction. However, it slowly gained acceptance and spread as a garden crop.

It gradually spread from northern Italy to the Rhineland along what was known as the Spanish Road, the route Spanish soldiers would take to get from Italy to the Netherlands and northern Germany. Since soldiers typically foraged for food, peasants were especially at risk during wartime. However, while the soldiers would take the grain that was stockpiled, they had neither the time nor desire to dig up something as disgusting to them as potatoes from the ground. And that saved a lot of peasants' lives during the Thirty Years War.

Tragically, the German peasants' problems were not over with the signing of the Peace of Westphalia in 1648, because another huge round of wars raged across Germany in the late 1600s and early 1700s thanks to Louis XIV's ambitions for power and glory. Luckily, the potato had spread across more of Germany, once again saving thousands of lives.

While something as mundane as the potato remained below the radar of most rulers, it showed up clearly in 1732 for the Prussian crown prince, Frederick, while at the siege of Philippsburg in

western Germany. Frederick was the epitome of the Enlightenment ruler, being interested in all the new sciences then emerging, including agriculture and clearly seeing the potato's potential. Therefore, when he ascended the throne as Frederick II (AKA the Great) in 1740, he ordered his peasants to plant it in their fallow fields, thus providing a valuable backup against famine and starvation.

Sixteen years later, it would prove to be one of the wisest things he ever did, because that was when the Seven Years War broke out, a war which proved to be the trial by fire for both Frederick and Prussia, having to face repeated invasions by both Austria and Russia, two powers that were each over twice the size of Prussia. During this war, he lost eight out of sixteen battles, but always had the resiliency and resources to come back after a defeat to drive the invaders out of his lands. The question baffling his enemies was how he and Prussia were able to survive the destruction of all these repeated invasions, and the answer to large extent was the potato.

After the Seven Years War, potato agriculture continued to spread across Europe, including to France by the time of its Revolution in 1789. One of the biggest innovations of the French Revolutionary and Napoleonic eras was the universal draft, which could field armies with hundreds of thousands of men to defeat the ring of enemies ganging up on France. Warfare waged on such a huge scale needed a corresponding jump in agricultural production to support it, and the potato again was at least part of the reason for that jump.

The march of the potato continued throughout the 1800s during the industrial revolution, this time sustaining the rapidly expanding industrial cities dotting the map. The potato did have its downside, namely the potato blight that hit Western Europe in the 1840s. While Ireland was especially hard hit, having no other major crops or a sympathetic government to back up the potato, other parts of Europe weathered the potato famine, often with relief from their governments.

THE ROOTS OF THE FRENCH REVOLUTION

"Walking up a long hill to ease my mare, I was joined by a poor woman, who complained of the times, and that it was a sad country. Demanding her reasons, she said her husband had but a morsel of land, one cow, and a poor little horse, yet they had a franchar (42 pounds) of wheat and three chickens to pay as a quitrent to one seigneur; and four franchar of oats, one chicken, and one franc to pay to another, besides very heavy tailles (income tax) and other taxes. She had seven children and the cow's milk helped to make the soup. 'But why, instead of a horse, do not you keep another cow?' Oh, her husband could not carry his produce so well without a horse; and donkeys are little use in the country. It was said, at present, that something was to be done by some great folks for such poor ones, but she did not know who nor how, but God send us better, 'car les tailles et les droits nous ecrasent' (for the taxes are crushing us).

"This woman, at no great distance, might have been taken for sixty or seventy, her figure was so bent and her face so furrowed and hardened by labor, but she said she was only twenty-eight. An Englishman who has not traveled cannot imagine the figure made by infinitely the greater part of the countrywomen in France; it speaks, at the first sight, hard and severe labor. I am inclined to think that they work harder than the men, and this, united with the more miserable labor of bringing a new race of slaves into the world, destroys absolutely all symmetry of person and every feminine appearance."-- Arthur Young Travels in France during the Years 1787, 1788, and 1789

The French Revolution, along with the Industrial Revolution, has probably done more than any other revolution to shape the modern world. Not only did it transform Europe politically, but also, thanks to Europe's industries and overseas empires, the French Revolution's ideas of liberalism and nationalism have permeated nearly every revolution across the globe since 1945. In addition to the intense human suffering as described above, its

origins have deep historic and geographic roots, providing the need, means, and justification for building the absolute monarchy of the Bourbon Dynasty which eventually helped trigger the revolution.

The need for absolute monarchy came partly from France's continental position in the midst of hostile powers. The Hundred Years War (1337-1453) and then the series of wars with the Hapsburg powers to the south, east, and north (c.1500-1659) provided a powerful impetus to build a strong centralized state. Likewise, the French wars of Religion (1562-98) underscored the need for a strong monarchy to safeguard the public peace. The means for building a monarchy largely came from the rise of towns and a rich middle class. They provided French kings with the funds to maintain professional armies and bureaucracies that could establish tighter control over France. Justification for absolute monarchy was based on the medieval custom of anointing new kings with oil to signify God's favor. This was the basis for the doctrine of Divine Right of Kings. In the late 1600's, all these factors contributed to the rise of absolutism in France.

Louis XIV (1643-1715) is especially associated with the absolute monarchy, and he did make France the most emulated and feared state in Europe, but at a price. Louis' wars and extravagant court at Versailles bled France white and left it heavily in debt. Louis' successors, Louis XV (1715-74) and Louis XVI (1774-89), were weak disinterested rulers who merely added to France's problems through their neglect. Their reigns saw rising corruption and three ruinously expensive wars that plunged France further into debt and ruined its reputation. Along with debt, the monarchy's weakened condition led to two other problems: the spread of revolutionary ideas and the resurgence of the power of the nobles.

Although the French kings were supposedly absolute rulers, they rarely had the will to censor the *philosophes'* new ideas on liberty and democracy. Besides, in the spirit of the Enlightenment, they were supposedly "enlightened despots" who should tolerate, if not actually believe, the *philosophes'* ideas. As a result, the ideas of Voltaire, Rousseau, and Montesquieu on liberty and democracy spread through educated society.

Second, France saw a resurgence of the power of the nobles who still held the top offices and were trying to revive and expand old feudal privileges. By this time most French peasants were free and as many as 30% owned their own land, but they still owed such feudal dues and services as the *corvee* (forced labor on local roads and bridges) and *captaineries* (the right of nobles to hunt in the peasants' fields, regardless of the damage they did to the crops). Naturally, these infuriated the peasants. The middle class likewise resented their inferior social position, but were also jealous of the nobles and eagerly bought noble titles from the king who was always in need of quick cash. This diverted money from the business sector to much less productive pursuits and contributed to economic stagnation.

Besides the Royal debt, France also had economic problems emanating from two main sources. First of all, while the French middle class was sinking its money into empty noble titles, the English middle class was investing in new business and technology. For example, by the French Revolution, England had 200 waterframes, an advanced kind of waterwheel. France, with three times the population of England, had only eight. The result was the Industrial Revolution in England, which flooded French markets with cheap British goods, causing business failures and unemployment in France. Second, a combination of the unfair tax load on the peasants (which stifled initiative to produce more), outdated agricultural techniques, and bad weather led to a series of famines and food shortages in the 1780's.

All these factors (intellectual dissent, an outdated and unjust feudal social order, and a stagnant economy) created growing dissent and reached a breaking point in 1789. It was then that Louis XVI called the Estates General for the first time since 1614. What he wanted was more taxes. What he got was revolution.

French gov't's revenues, expenses, and debt in the years leading to the French Revolution

Marie Antoinette's Peasant Cottage

Apparently, all those idle days of aristocratic life were so boring that Marie Antoinette had a fake peasant cottage built at Versailles where she could play peasant with her friends. Unlike most peasant cottages, it was furnished with Swiss style tapestries, mahogany chairs, stone slab floors, a library, and harpsichord. The queen even had molds of her breasts fashioned into bowls from which to feed milk to her perfumed sheep and goats.

While the cottage did provide a diversion for the queen and a rustic ambience to Versailles, it also had its more serious side, functioning as a real farm that provided dairy products and other produce for the royal table. It was modeled on a similar farm built by the Prince de Conde and was part of a more widespread attempt by France's aristocracy to experiment with more modern agricultural techniques along the lines advocated by reformers, known as the Physiocrats.

Social Classes in Pre-revolutionary France

A Sans Culottes woman as portrayed by Jacques Louis David

At the time of the revolution France had a population estimated at 28 million. Of those, 130,000 (0.5%) belonged to the First Estate (clergy) and 400,000 (1.5%) were in the Second Estate (nobles). Together, those two classes owned about 40% of France's land, twenty times

more than their rightful share if the land were evenly distributed. However, that land wasn't even fairly distributed within those classes, with there being a few fabulously wealthy clergy and nobles and a preponderance of poor to moderately well-off nobles and very poor parish priests.

The other 98% of the population, the Third Estate (those who worked) was further divided into a number of sub-groupings, each of which tried to maintain its status in the pecking order above at least some of the others. At the top, and in some cases wealthier than the richest nobles and clergy, were the bourgeoisie: rich landowners, bankers, and officials who still technically ranked below the nobles and clergy. Naturally, their ambition was to be accepted into the ranks of the higher nobility, who in turn tried to exclude them from their ranks in the spirit of the meanest high school teenagers. One common story was of the bourgeoisie woman invited to a nobles' dinner party, only to be sent to the kitchen to eat with the servants. The most common way to crack the ranks of the nobility was to buy offices and titles, which over 50,000 members of the Third Estate had done by the Revolution.

Next in line were the *petit bourgeoisie*: upper middle class professionals such as doctors, professors, and lawyers. They were educated, had read their Locke and Rousseau, and were especially anxious for change. Maximilien Robespierre, Georges Jacques Danton, Camille Desmoulins, and Jean Paul Marat were all lawyers from this group who would play prominent roles in the Revolution. They were also prime examples of the idea that revolutions are started by those who already have something and want more.

After the *petit bourgeoisie* came the *sans culottes*, basically the class of poor urban laborers, craftsmen, and shopkeepers. Their name literally meant "without knee-breeches", the fashionable short pants worn by the more well-to-do who could afford silk stockings to complement them. Instead, the *sans culottes* wore long trousers, which came to symbolize the

radical democratic ideals they stood for. They provided the "cannon fodder" of the revolution and exerted influence over its events far out of proportion to their numbers, probably representing only about 10% of France's population. Within their ranks the *sans culottes* had their own pecking order. At the top were skilled craftsmen, in particular furniture makers, while at the bottom were common laborers, most notably bakers' assistants, who were described by one contemporary as a "wild and savage breed of cavemen."

Then there were the other 85% of the population who lived in the countryside: the peasants. While on the whole they had gained their freedom from the two or three days of mandatory labor on their lords' land, they still suffered the burdens and indignities of numerous feudal dues and obligations, including having to pay to use the lords' mills and ovens. They, of course had their own pecking order, led by the 30% or so who owned their own land. The rest of them either rented or share cropped the lands of rich bourgeoisie, clergy, or nobles. Fixed rents were generally considered a better deal, since continuing inflation would gradually lower their value and burden.

The "Cult" of Franklin

Upon his arrival in Paris in December 1776 to solicit aid for the American Revolution, Ben Franklin was hailed as the "Apostle of Liberty". He was already seen as sort of a saint for his invention of the lightning rod. In addition Parisians saw his simple life style of living in a modest house outside Paris and wearing a trapper's fur hat instead of a powdered wig as a perfect example of how the colonists had attained a state of natural grace, combining the

best of European culture with living close to nature. Of course Franklin, who had become the object of a virtual cult, did nothing to correct the French public's perception of the colonists.

Prior to, Diderot's Encyclopedia listed ringing church bells as the preferred way to dispel electrical storms, which led to numerous deaths of bell ringers hanging on to ropes attached to the highest piece of metal in town. Thanks to the success of Franklin's lightning rod, Diderot changed the encyclopedia, advising readers to use lightning rods to divert dangerous lightning strikes. However, when a man in St Omer set up such a lightning rod in 1780, his neighbors sued him to take it down, thinking it would have the same effect as ringing church bells. The lawyer who successfully defended him was Maximilien Robespierre, while the prosecuting lawyer was Jean Paul Marat, both of whom would emerge as leaders of the Revolution.

ANALYZING THE FRENCH REVOLUTION AND REVOLUTIONS IN GENERAL

Introduction. When analyzing the French revolution and revolutions in general, there are several recurring aspects we should keep in mind. For one thing, revolutions tend to develop like a fever that starts mildly, but worsens progressively until it reaches "fever pitch" and then breaks. This cycle may recur several times before matters finally are resolved. A second theory is that revolutions start out rebelling against an absolutist or arbitrary power and end up setting up another arbitrary power in its place. The French Revolution certainly fits into both of these patterns. Finally, the revolutions that succeed do so because the ruling regimes are too weak willed to crush the opposition early before matters get out of hand. That was the case with England in the 1640's, Russia in 1917, and certainly with France in 1789. However, even a corrupt and decaying government, is if it acts decisively at the start, can usually crush a revolution before it can spread and grow.

The French Revolution. All this makes sense when one considers that a revolution is against an order that people have come to depend on over a long time. Most people, however dissatisfied, are still reluctant to get rid of that "security blanket" and take their chances with something new and untried. Therefore, successful revolutions, like fevers, start off small and moderate. This has its good and bad points. For one thing, their moderation makes them seem safer to more people and does not invite a severe crackdown by the authorities. In fact, at this early stage, a revolution may seem more like a reform movement than a revolution. That was largely the case with the very moderate National Assembly that took power in 1789.

However, the very moderation that makes a new regime such as the National Assembly so widely acceptable also creates problems in a couple ways. First of all, in order to seem legitimate, the government feels it must hang onto many of the very policies and symbols that had triggered the revolution in the first place. In the National Assembly's case, it was keeping the king as a figurehead and honoring his debt. In the Russian

Revolution it was keeping Russia in the First World War. In both cases, these policies, while making the new governments look more legitimate, also severely undercut their power. Second, the new regime's moderate policies keep it from taking the drastic measures necessary to solve the problems that led to revolution in the first place, since that would seem to betray the principles of the revolution. Despite these shortcomings, the new regime leads to high expectations that it will solve the nation's problems.

However, a major problem the new regime faces is that the transition to a new government will cause a good deal more confusion and turmoil before it starts turning things around. The new regime's failure to solve the nation's problems quickly just adds to the frustration of people who expect a quick fix to the country's problems and do not understand that solutions to such deeply rooted problems take time. This leads to a vicious cycle that will drive the revolution to a crisis stage.

First of all, more radical elements will exploit the government's problems and weaknesses in order to seize power. In France those "radicals" were the Girondins, who were still relatively moderate. They in turn found themselves faced with many of the same problems the original National Assembly had as well as high expectations that they would solve them. Unfortunately, the more radical the revolution gets, the more alarmed neighboring countries become about the prospects of the revolution spreading. Also the more turbulent the revolution, the more tempting it might be for outside powers to intervene for their own greedy purposes. This results in the other countries ganging up against the revolutionary country, as happened to France in 1792. Naturally, internal anarchy makes the revolutionary regime ill prepared for war and it starts losing. This creates more internal turmoil, giving a new group of radicals the opportunity to gain support and seize control, which is what the Jacobins did in France. This feeds back into alarming foreign powers who increase outside pressure on the revolution, thus triggering more confusion and turmoil, and so on.

At some point, this mounting feedback between internal anarchy and military defeat leads to three things. First of all, the revolution reaches a crisis stage where someone has to take firm control of

affairs if the nation and revolution are going to survive. In the French Revolution, the Jacobins organized France into what was in essence a police state under the "reign of terror". However these measures, including a universal draft that led to huge armies by the standards of the day, did provide the internal order and productivity necessary to support France's armies.

However, the revolution has also unleashed two other factors that will help save it. One of these consists of new ideas and symbols, in particular nationalism, which inspired the French people to fight, sometimes with inspired fury, for a nation they now saw as their own, not the king's. Finally, the revolution freed the French to think in innovative ways, especially in the form of new military tactics introduced by a new generation of officers who had taken the place of the departed nobles. This combination of nationalism, new military tactics, and police state measures saved France in the crisis of 1793-94. But the revolution was not finished yet.

As stated above revolutions tend to go from arbitrary power to arbitrary power. This happened with Cromwell's military dictatorship in the English Revolution and with Lenin's dictatorship in Russia. It also happened in France. With the passing of the crisis of 1793-94 there was a backlash against the radical Jacobins and their reign of terror. A more moderate government, the Directory, took over and found many of the old problems (e.g., food shortages and inflation) re-emerging. It also found a new coalition of foreign enemies ranged against it, even more scared of the revolution after its recent, nearly miraculous comeback. In such a situation, the solution lay with the army, much as it did with Cromwell's New Model Army in England and Lenin's Red Army in Russia. Likewise, in France, it was an ambitious young artillery officer, Napoleon Bonaparte, who seized power and established a military dictatorship.

On the surface, it may seem that Napoleon killed the French Revolution and that nothing had been gained. However, one should keep in mind it was powerful revolutionary forces that brought him to the top and gave his army the power to march across and dominate Europe. Napoleon may have tamed the revolution's more chaotic aspects and

stifled its more radical innovations (especially in the way of democracy), but he also consolidated it. He kept and expanded its administrative and economic reforms. He codified into law its principles of social and legal equality for all men. And he shamelessly used the concept of nationalism to inspire his armies in battle. He also provided the stability necessary for economic growth and the further rise of the middle class. And it was the combination of repressing parts of the revolution and fostering others that gave Napoleon and France the power to conquer or dominate nearly all Europe by 1807.

Whether or not he meant to, Napoleon also spread the revolutionary ideals of liberalism and nationalism across Europe where they took root and grew into a force largely responsible for his eventual defeat. Foreign powers armed the masses and invoked the power of their own nationalism to defeat Napoleon by 1815. Long after Napoleon the ideas of the revolution imbedded in the law codes he had imposed upon Europe continued to take root and grow, first in Europe, and then by way of Europe's colonial empires, across the globe. Then it was the turn of non-Europeans to use the powerful ideas of the French Revolution to overthrow European rule in much the same way that Europeans had used those same ideas to overthrow Napoleon. When put into that kind of perspective, one can see what a powerful force the French Revolution has been in modern history.

The Cult of the Nation

Even before the French Revolution, Europeans were conceiving of the nation in personal terms, portraying it as a young and pure woman for which they would willingly fight and die as martyrs, much as early Christians had been martyred for the Church. The French even had a name to further humanize their symbol: Marianne (above).

Below are several quotations from various men of the 1700s expressing this quasi-religious devotion.

“A nation can only regenerate itself in a bath of blood.”—Diderot

“I long to die for such a true cause; I wish to expire on the bed of glory; I wish to perish at my post.”-- Kasimir Pulaski

“We are ready to let ourselves be buried under the ruins of our liberties”—Etienne Claviere, Genevan revolutionary

“Yes, this delightful land which we inhabit and which nature caresses with love is made to be the domain of liberty and happiness...I am French, I am one of thy representatives...Oh, sublime people! Accept the sacrifices of my whole being. Happy is the man who is born in your midst; happier is he who can die for your happiness.”-- Robespierre

The apotheosis (transformation into deities) of heroes of the nation was another major element of the Cult of the Nation, being bestowed on such leaders as Ben Franklin, Voltaire, and George Washington, whose apotheosis is celebrated in the dome of the Capitol building,

Paintings of heroes who died in the nation’s defense were typically portrayed in the same way as Christian martyrs previously had been depicted. Particularly notable was *The Death of Barra* (below) a painting done in 1881 glorifying the legendary death of a 13-year old French boy who died defending Napoleon’s cavalry horses from brigands. Some 500,000 copies of this painting were distributed to French schoolboys to inspire their patriotism

THE START OF THE FRENCH REVOLUTION (JULY, 1789 JULY, 1790)

Hopes ran high for widespread reforms when Louis XVI called the Estates General to Versailles in the spring of 1789. While Louis' main concern was to get more taxes to cover France's mounting debts, the delegates from the Third Estate (mostly middle class lawyers and businessmen) came with notes (*cahiers*) from their constituents urging such reforms as taxing the clergy and nobles to even the tax burden. However, before these issues could be addressed, a more basic problem arose: voting procedure.

The First and Second Estates (clergy and nobles respectively) wanted bloc voting where each estate's votes collectively counted as one vote. This would give the nobles and clergy two votes to one for the Third Estate (representing the middle and lower classes who comprised 98% of France's population). Therefore, the Third Estate, whose delegates equaled the combined number of noble and clergy delegates, wanted one vote per delegate. Since a number of liberal clergy and nobles would probably vote with the Third Estate, this would give the Third Estate an effective majority of votes.

The decision belonged to Louis, whose weak and indecisive nature let matters get out of control. On June 17, the Third Estate, seeing the king's indecision, put pressure on him by withdrawing along with many poor delegates from the clergy and declared themselves the National Assembly with the exclusive right to grant taxes. When Louis locked them out of the Assembly Chamber, they withdrew to an indoor tennis court and took what became known as the Tennis Court Oath, vowing never to separate until they had formed a constitution. Somehow, a meeting about taxes had turned into a movement to form a new government. On June 27, Louis gave in and ordered the First and Second Estates to merge with the National Assembly. The Revolution had begun.

Two weeks later, on July 10, Louis, under pressure this time from the nobles, ordered troops to surround Paris and Versailles. The next day he fired a popular finance minister, Neckar, who had advocated taxing the nobles. These acts, plus continued food shortages triggered demonstrations

in Paris that culminated in the storming of the Bastille (7/14/1789), an old prison with so little value that Louis himself had plans for tearing it down. Despite this, the Bastille was a symbol of oppression and its storming has been celebrated ever since as France's Independence Day.

All across France the Bastille's fall touched off the Great Fear, waves of violence in which armed bands of peasants killed nobles and royal officials, burned chateaus, and destroyed records of feudal obligations. This created several effects. First, concerned property owners in cities throughout France took the lead from Paris and formed their own National Guard units to protect themselves and their property. As a result, France now had two armies: the king's royal army and the revolution's National Guard. Also, the mounting violence and chaos started a wave of nobles emigrating to other countries. Successive waves of emigration would bring stories of ever mounting turmoil in France that would stir up foreign fears, hostility, and eventually full scale military attempts to overthrow the revolution. The resulting wars would rage across Europe for a quarter century.

Finally, fear of violence also seems to have affected the National Assembly. On the night of August 4, 1789, nobles and clergy surrendered their feudal rights and privileges in a remarkable show of generosity (or fear). In one fell swoop, feudalism had been abolished in France, although the final draft of the document did give compensation to the nobles and clergy and delayed dismantling the feudal order.

In much the same spirit, the National Assembly issued the "Declaration of Rights of Man and Citizen" (8/27/1789). This remarkable document declared for all men, not just Frenchmen, the basic ideals of the revolution: liberalism (the belief in civil and political rights and liberties for all men) and nationalism (the belief that a people united by a common language and culture should control its own destiny). These two principles have proven to be two of the most powerful ideas in modern history.

Center stage now moved back to the Paris mob of laborers and small shopkeepers, known popularly as the *sans culottes* from their wearing long pants rather than the more fashionable short breeches

(culottes) of the upper class. Partly inspired by the Great Fear and the acts of the National Assembly, but even more by continued food shortages, they marched on Versailles and brought the king and National Assembly back to Paris to ensure they would relieve the suffering of the urban poor. From this point on, the *sans culottes* would exact an ever more powerful and radical influence on the French Revolution, a power and influence far out of proportion to their numbers.

However, the Revolution at this point was still a fairly mild and civilized affair controlled by moderate middle class delegates. It was the enlightened ideas of such philosophes as Rousseau and Voltaire plus the growing need for reforms, not pressure from the *sans culottes*, that mainly influenced the constitutional monarchy they established in July, 1790. Power mostly resided in the National Assembly, with the king having only a weak temporary veto on its actions. In order to weaken old feudal loyalties, France was broken up into 83 new provinces known as *departements*, the basis of France's administration to this day. Jury trials were established, torture was outlawed, and a more humane form of execution, the guillotine, was introduced. Internal tolls were abolished, and a standard system of weights and measures, the metric system, came into use. The new constitution definitely had a narrow middle class bias, as seen by its measures to improve trade plus its property qualifications for voting that shut out all but 4,000,000 Frenchmen from full citizenship. It was a combination of the new government's more progressive measures and shortcomings that would lead to more radical reforms.

One problem the National Assembly did not solve was the huge royal debt that had started the revolution in the first place. Since the king was kept as constitutional figurehead of the government in order to make it look legitimate, the National Assembly could not repudiate the royal debt and still seem credible. Therefore, it came up with one of the more innovative policies of the revolution: confiscation of Church lands, the value of which would back up government bonds called *assignats*. The National Assembly originally sold 400,000,000 francs worth of *assignats* to pay off its most urgent debts.

Unfortunately, many people saw the *assignats* as money and used them rather than hard cash to pay their taxes. As a result, the Government, finding itself still in need of cash, issued more *assignats* and the cycle started all over. There were two main results of the government's Church policies. First of all, the flood of *assignats* triggered an inflationary cycle that destabilized the French economy and political structure. By the end of the revolution, the *assignats* were only worth 1% of their face value. Second, many people were angry over the state's control of the Church that extended to electing priests and making them swear a loyalty oath to France. Both of these would combine to unleash forces making the revolution more radical and violent.

Dress Codes and other Annoyances

Sometimes it's the little irritants in life, like dress codes, that lead to conflict. Among other things, Third estate deputies resented restrictions in the fanciness and color of the clothes that they could wear (black) compared to the clergy's vestments and the nobles' silk fabrics, swords, cloth-of-gold waistcoats, and white plumed hats. In addition, the Third Estate was usually not even allowed to meet in the same room as the other two estates.

Or, if there were a common assembly, such as opened the Estates General on May 4, 1789, they had to wait until the First and Second Estate members had entered and sat down to the left and right of the podium before they could enter and sit in the back. When the king entered everyone would stand and remove their hats until the king had been seated. Then the nobles and clergy could sit and replace their hats while the Third Estate remained standing for some time. In a sense, the first act of the Revolution was when the Third Estate sat at the same time as the other two estates. It was probably a good thing they did, because the initial meeting of the Estates General was so long that Neckar needed help finishing his own three hour long speech.

The King

Louis XVI was just the wrong person in the wrong place at the wrong time. He wasn't evil, even being a devoted family man. But he wasn't much of a king either. Seen as being fat, dull, and stupid, he was the unwitting butt of jokes in his own court. He was so nearsighted that he couldn't recognize anyone more than three paces away. Instead of a kingly gait, he shambled along like a peasant behind a plow. Much more than ruling, he was interested in locksmithing and probably would have been more content if he had been born a simple locksmith.

But Louis' real passion was hunting and he considered a day without shooting a stag as a day lost. Yet he reportedly was too lazy for the chase and would have deer driven by his window where he could shoot them. He was also an obsessive list keeper and during his reign (1774-89) he claimed to have killed 189,251 game and 1274 stags. On July 14, 1789, the day the Bastille fell, he entered one word in his diary: "Nothing," referring to the number of animals he killed that day.

Like Louis XIV, he had a huge appetite, so he was fat, but also quite strong, sort of a gentle giant. A cartoon of the time showed Henry IV meeting his descendant, Louis XVI transformed into a pig wallowing in a wine barrel.

He was also reluctant to order the execution of humans. As a result, when he ordered the Swiss Guards to stop firing against the mob attacking

his palace, he was captured and eventually executed. Worst of all, especially for him, Louis was terminally indecisive letting matters get out of control so that even a simple squabble over voting procedure would lead to revolution and his overthrow.

The Queen

Marie Antoinette was the youngest daughter of the Austrian Empress, Maria Theresa. Although spoiled and somewhat flighty, she was hardly the monster that public opinion and later historians made her out to be.

However, Louis' indecisiveness, her foreign birth, and traditional prejudice against women in power (or perceived to be in power) led people to believe she was a spendthrift misleading the king and France to ruin. Although hardly a saint, she also wasn't the witch of popular imagination.

In fact the court was trying to tone down its image to keep in line with the late Enlightenment's sensitivity to nature and the simple life. Therefore, the official public image we get of Marie Antoinette through the brush of her official court portrait artist, Elizabeth Vigee-Le Brun, is one of a devoted mother instead of a decadent queen.

Unfortunately for Marie, the seclusion of court life gave the French public little opportunity to see this side of her. Only recently have historians begun to reconstruct a more accurate portrayal of this woman.

The First Hot Air Balloon Flight

In place of high society parties, Versailles was host to more events of public interest. Probably the most notable of these was one of the first hot air balloon flights. The king was so concerned about the safety of the balloon's inventors, Joseph and Jacques Montgolfier, two paper mill owners, he wouldn't let them fly with the balloon. Instead, the first passengers were a rooster, a sheep, and a duck.

The Montgolfiers did perform the first manned air balloon flight (above) and the first hydrogen balloon flight, also in 1783. All these events drew huge crowds from Paris and other surrounding towns. The first flight, on June 4, 1783, ascended 6,562 feet in the air.

Not that everyone was thrilled. Peasants, not aware of these balloon achievements, attacked the balloons when they landed in their midst, figuring it must be some sort of alien invasion.

The Revolution Begins: the Tennis Court Oath

On June 17, the Third Estate, seeing the king's indecision over the voting issue, put pressure on him by withdrawing along with many poor delegates from the clergy and, in the spirit of Rousseau, declaring themselves the National Assembly with the exclusive right to grant taxes, since only they paid them. When Louis (an accomplished locksmith) locked them out of the Assembly Chamber, they withdrew to an indoor tennis court. After a day of trying to organize

and get over 500 delegates to agree on one common statement (a remarkable accomplishment in its own right), they took what became known as the Tennis Court Oath, vowing never to separate until they had formed a constitution. It was immortalized in Jacques Louis David's painting (above)

Somehow, a meeting about taxes had turned into a movement to form a new government. On June 27, Louis gave in and ordered the First and Second Estates to merge with the National Assembly. The Revolution had begun.

On June 22, 1789 Louis called everyone together and announced reforms (maybe even taxing the nobles). He ended by "asserting" his royal authority and then left, followed by clergy & nobles. However, the Third Estate refused to leave.

When informed of this, the king sent troops to clear out the protestors. However, joining the Third Estate were 47 nobles sympathetic to their demands. Since custom demanded that nobles at Versailles wear swords, their presence and the threat of violence convinced Louis to let the Third Estate stay.

The scene now shifted to Paris.

Paris before the Revolution

If one city epitomized the 18th century, it was Paris. With a population of 600,000 crammed into an area of six or seven square miles, it presented sharp contrasts between the luxury of the rich and the abject poverty of most people. Being so big by the standards of the day, it struck visitors as almost another planet.

One prominent feature of the city was its fourteen bridges. The busiest and most populous bridge was the Pont Neuf which had 178 stalls and shops where you could get anything money could buy. That also made it very dangerous at night, so the stalls and shops were destroyed in 1756. The Pont Notre Dame had 68 three-story buildings, including 14 goldsmith shops. Those were torn down for safety in 1786. Along the right bank the Seine, one could find more luxury marts.

Population was especially dense in the center of the city on the Ile de la Cite, and in surrounding areas. Living conditions for workers here were particularly bad, with one room for both living and working. There was also the Cour des Miracles behind a cemetery, where, after a hard day of begging, fraudulent beggars would remove their disguises and emerge transformed as if by miracle.

The city was also crowded with churches and monasteries. There was a series of royal edicts prohibiting construction beyond certain points so the population didn't outgrow the food supply, but Paris continued to grow despite these and also without any central planning, which led to various problems and occasional riots.

The major geographical feature making Paris possible was the Seine River, which allowed the transport of vital supplies of food and building materials. To expedite distribution, different ports were reserved for different goods: stone, wood, fresh fish, grain, wine, etc. Of course, all this was jeopardized in times of intense cold, drought, or flood, so such a huge city was especially at the mercy of the forces of nature.

The city's water supply also came from the Seine, which in 1760 supplied sixty fountains, although it needed ten times that number. In response, those who could afford to either dug wells or bought from water carriers. Running water was unknown except to a few very rich and was not even halfway common until 1800.

Streets, were still narrow, winding, dark, and filthy, basically just a maze of alleys and cul-de-

sacs that couldn't handle traffic, commonly leading to fights between two parties each claiming it had rank over the other. There were only two major east-west boulevards and a few more running north-south.

Buildings were asymmetrical and poorly built, causing them to sag, bulge, and sometimes collapse. Because lateral space was so limited, people built up, so that sunlight rarely reached even the windows facing street. A law passed in 1783 mandated the streets to be at least 10 meters wide and building no taller than the width of the street, but no one listened.

Most people walked since coaches and sedan chairs were too expensive. Still, there were too many carriages for the crowded streets, and they often ran people, especially children, down. Many people were of the opinion that life on the streets was depriving children of much needed exercise, leading to bodily deterioration and early deaths.

Besides being crowded and dangerous, Paris' streets had filth everywhere.

Proprietors were supposed to sweep in front of their houses and garbage, which was supposed to be collected daily, instead steadily piled up, attracting vermin of every kind and producing astounding odors. Adding to the smell were open burial pits, an estimated 2,000 decomposing bodies a year, and blood running out the doors of butcher shops and horse skinning establishment into the street gutters, which were just open trenches in the middle of the streets. Another sanitary problem and hazard was ordinary household waste thrown from chamber pots with alarming frequency. Passing police patrols were popular targets. In response, wide brimmed hats, thick boots, and walking to the outside to protect a lady against filth splashing up from the street became customary.

Some streets did have certain social and professional distinctions, but neighborhoods and houses typically had various classes mixed in, social distinction determining the story one lived on: the higher the story, the lower the status and likelihood of escaping a fire.

Getting lost on Paris' streets was another major problem, so ten-foot metal signposts were set up in 1728... and quickly knocked down or stolen by cranky Parisians. So street signs were engraved into buildings' cornerstones. In 1775 buildings were numbered and reflecting oil street lamps were put in to replace the older and more cumbersome candlelit lanterns. By 1789, the city had 3528 lampposts, which proved convenient for lynching. The first sidewalks were also installed in 1789, but that didn't stop the revolution.

The Bastille (July 14, 1789)

On July 10, Louis, under pressure this time from the nobles, ordered troops to surround Paris and Versailles and the next day fired the popular finance minister, Necker. These acts, plus continued food shortages, triggered demonstrations in Paris.

In order to protect their property from the growing turmoil, Parisians formed armed patrols that "would spring up across France's cities and become its revolutionary army, the National Guard.

Adding to the hysteria were radical leaders such as Camille Demoulin who stood on a café table and stirred up growing fears of royal troops attacking Paris and the National Assembly.

On July 14, the *sans culottes* made their move.

The initial target for the crowd of about 8,000 was the Hotel Invalides, which had 30,000 muskets, but no powder. So they moved on to the Bastille, an old prison of so little value that Louis himself had plans for tearing it down. However, along with being a symbol of government repression, it had 30,000 pounds of gunpowder stashed there two days earlier. It also was supposedly full of political prisoners waiting to be freed, always a popular issue in such times.

After milling around for a while in the July heat, which just made the *sans culottes* hotter, hungrier, thirstier and madder, someone cut the chain to the drawbridge of the outer curtain, which fell on a fellow demonstrator and killed him. As the crowd stormed in, the garrison opened fire, killing 94 people.

After a while, De Launay, the Bastille's commander, sent out a note threatening to blow up a large part of the city along with himself, the Bastille, and his garrison, something his men weren't too wild about. For whatever reason, they negotiated a surrender and safe conduct for the garrison.

Despite the promise of a safe conduct in return for surrendering the Bastille, its commander, De Launay (left), and 6 other soldiers were beheaded by the mob, their heads then carried on pikes across the city.

Caesar's return. Despite all the fuss about political prisoners being held in the Bastille, the mob forgot to free them until later that night. By that time, the man to whom the keys to the prison had been surrendered had gone home, so the crowd had to batter down the doors, finding

only seven prisoners, none of whom could be counted as “political”.

Four of the “political” prisoners were in there for forgery, one for debauchery, and one thought he was both Caesar and God. When the sans culottes freed him and carried him in triumph through the streets, he must have thought he was enjoying a Roman triumphal march with all the adoring Roman citizens cheering him for conquering Gaul (aka France) and massacring or enslaving its inhabitants.

Inspired by the storming of the Bastille earlier that day, people on the outskirts of Paris attacked, sacked, and burned the royal customs barriers that taxed any goods or produce coming into the city. Interestingly, the Parisian women at one station paid what they considered a fair price for the food instead of stealing it.

Two days after its storming, the Bastille was demolished, its bricks being turned into miniature models of the old fortress and sold as souvenirs.

On July 17, Louis came to Paris where crowds cheered him as he toasted the Revolution and donned the revolutionary Phrygian cap worn by the Sans Culottes. These hats were derived from liberty caps given by Romans to freed slaves. The red, white, and blue cockade on the side represented Paris (red and blue) and the Bourbon dynasty (white). Liberty caps could also be seen atop every liberty tree and flagpole, during the Revolution.

The Great Fear and End of the Feudal Order (Summer, 1789)

The Great Fear that swept through much of the French countryside in the months following the fall of the Bastille. It was a paranoid and hysterical reaction to rumors that the nobles and Queen were going to sabotage the Revolution.

Poor communications and the absence of hard fact led to wild rumors spreading across France. Even a cloud of dust stirred up by cattle coming in from the fields could raise an alarm across the countryside that armies of brigands hired by the nobles were coming to attack the peasants.

Similarly, even sunsets were mistaken for burning villages. Peasants would stand guard over their fields against any counter-revolutionaries who might try to sabotage the crops

One of the more bizarre rumors during the Great Fear was that the queen was plotting to blow up the National Assembly, sneaking the gunpowder in under her skirts. That would require remarkably big skirts or the invention of C4 explosives.

The violence finally subsided when it was time to harvest the crops. Revolutions are fine, but you still have to eat.

The end of feudalism on the night of August 4, 1789 was brought on by a combination of fear, altruism, and even jealousy between the first two estates. It started with rich liberal nobles who could afford to lose feudal dues. Then a bishop denounced the nobles’ hunting rights, inspiring a duke to call for the end of tithes, pluralism, and other church privileges. Caught up in the moment, various nobles voluntarily gave up the

privileges of their own offices, making them open to merit. Others caught the fever and by 2 AM had swept away the entire feudal order in a fit of revolutionary fervor (and Great Fear).

One can imagine the hangover of regret the next day as nobles and clergy awoke to the realization that they had thrown away all their hereditary rights. In addition, their fellow nobles and clergy might not be overjoyed at the news. Therefore, they tried to soften the blow by making the peasants pay compensation to their lords for the lost labor and privileges. However, the momentum of violence in the countryside propelled peasants to claim equal rights, refuse to work for the nobles, and seize land as their own.

The March of the Heroines (10/5-6/ 1789)

Center stage now moved back to Paris. Although the harvest had been good, it had not reached Paris yet. So the Parisian women took the lead and marched on Versailles to demand food. Women were often at the front of demonstrations, since the king's troops were less likely to fire on them. But these weren't dainty little ladies. When they marched on Versailles (ten miles in the rain, no less), they killed and beheaded guards who tried to prevent their entrance.

Once there, they stormed into the gallery of the Hall of the Constitution at Versailles where the National Assembly was meeting. The next day they broke into the palace and headed for the queen's quarters, tracking her to the king's quarters, where they had the royal family cornered for nearly an hour before being convinced to leave by the king promising to return to Paris with them.

Therefore, a procession of the Heroines, now accompanied by 15,000 National Guardsmen, escorted Louis "the baker," his family, and the National Assembly from Versailles to Paris to ensure they would relieve the suffering of the urban poor. From this point on, the *sans culottes* would exact an ever more powerful and radical influence on the French Revolution, a power and influence far out of proportion to their numbers.

France Goes Metric, but America Doesn't

In 1790, the French Academy determined to simplify weights and measures in France, declaring it should be one ten millionth the measure of the distance from the equator to the North Pole along the Paris meridian. After that, all they had to do was make that measurement. Amazingly, when Jean Delambre and Pierre Méchain completed their survey in 1799, they were only about 0.023% off in their measurement. The next year, France officially went metric.

Currently, the U.S., Liberia, and Myanmar stand alone in the battle against global metric tyranny. Not that there haven't been efforts in the U.S. Most notably, Congress passed the Metric Conversion Act of 1975 "to coordinate and plan the increasing use of the metric system in the United States". Metrication was not mandated however, and the U.S. Metric Board (USMB) lacked the power to enforce metrication. Despite public service announcements and road signs listing both miles and kilometers, the USMB had no real backing from Congress and was disbanded in 1982.

However, the Omnibus Trade and Competitiveness Act of 1988 mandated use of the metric system by government agencies, as well as aiding businesses in the conversion. The military generally uses the metric system since it often has to coordinate actions with other militaries.

In 1998, the Mars Climate Orbiter was lost because, despite requirements that all sub-contractors use the metric system, Lockheed

Martin, provided thruster performance data to the team in pound force seconds instead of newton seconds. As a result, instead of orbiting at a height of 150 kilometers, it descended to 57 kilometers and burned up in the Martian atmosphere.

Priests as Civil Servants

Figure of a clergyman trapped under the Phrygian cap, symbol of the Revolution

The Civil Constitution of the Clergy was the document requiring France's clergy, now state employees, to swear an oath to France that superseded their oath to the Church. Most clergy (130 of 134 bishops and 46,000 of 70,000 priests) refused to take the oath. Those taking the oath were referred to as juring priests, those refusing as non-juring. Some parishes had both juring and non-juring priests. People more loyal to the state would attend masses held by juring priests. Those more devoted to the Church went to masses held by non-juring priests.

THE REVOLUTION HEATS UP (JULY, 1790-- SEPTEMBER, 1792)

At the first annual celebration of the revolution 50,000 National Guardsmen from all over France and 300,000 Parisians witnessed the king taking an oath of loyalty to the new constitution. However, Louis was not loyal to the revolution since it severely restricted his power and even prevented him from leaving Paris to attend Mass in the country. On June 20, 1791, the king tried to escape to the Austrian Netherlands and seek refuge with the Hapsburgs. Unfortunately for Louis, everything went wrong. Detachments of royal troops failed to meet him in time. Then, despite Louis' disguise as a German servant, a postmaster at Varennes recognized him from his portrait on the assignats. The postmaster called out the National Guard who captured Louis and escorted him back to Paris. Whatever faith most people may have had in their king before was now shattered by his attempted betrayal of the revolution.

Louis' foiled flight was a turning point in the revolution. First, it further alarmed foreign royalty about the mounting revolutionary threat in France. Second, it widened the rift between the radicals who wanted a republic (democracy without a king) and the bourgeoisie (upper middle class) who wanted to keep the king as figurehead to maintain the moderate respectable image of the revolution. To protect Louis and their position, they claimed the king had not fled but had been kidnapped. At the same time they suspended Louis' powers. But the damage had been done. In July, a demonstration of 50,000 Parisians demanding Louis's abdication turned violent and the National Guard killed 50 demonstrators. The revolution was starting to fragment.

On September 30, 1791 the National Assembly dissolved itself after over two years of leading the revolution. One of its last acts was to exclude its members from re-election to the new National Assembly, thus bringing in new blood, but also eliminating many experienced leaders from participation as well.

The elections of 1791 showed how fragmented the revolution was becoming. On the left wing (sitting to the left of the speaker's platform in the assembly) were the radicals led by the Jacobins who wanted a more strongly centralized republic. Next to them and controlling the most votes were the Girondins who also favored a republic, but with more provincial freedom from central control in Paris. Just to the right of them were moderates who were happy with their gains from the revolution and resisted further change. To the far right were the monarchists who wanted to restore the feudal order and the king's power. These were not so much organized political parties as they were loosely organized networks of political clubs united by a common political philosophy.

While the Girondins had been able to exploit the moderates' problems in order to gain power, they soon found themselves faced with the old issues of food shortages, inflation, and debt. A new problem was also surfacing that would soon overshadow the rest: war. Ironically, this was the one issue most people agreed on, but for widely different reasons. Louis and the monarchists saw war as a chance for Austria and Prussia to crush the revolution and restore the king to power. The Girondins saw it as an opportunity to discredit Louis and spread the revolution across Europe. War could also divert attention from France's internal problems. Many Frenchmen saw war as a means of preventing nobles from returning to reclaim their lands and feudal rights. Austria and Prussia wanted war to prevent the revolution from spreading outside of France. With everyone in such agreement, France declared war on Austria and Prussia (4/20/1792). This triggered a series of wars between France and the rest of Europe that would last, with few breaks, for 23 years.

The government was optimistic about the war. It should have known better. The combination of old and new debts plus inflation triggered by the *assignats* had left the treasury in shambles. Likewise, the incomplete transition from the royalist army to a national one had left the army in disarray. Royalist and National Guard units operated separately from one another. Noble officers had either fled or were of suspect

loyalty. And the troops, while enthusiastic, were poorly trained, supplied, and led.

The result was a total fiasco as French troops fled at the first sight of the enemy. Charges of treason flew everywhere, especially against Louis, who probably was plotting with the enemy. An ultimatum ordering the French not to harm the king seemed to confirm suspicions of his guilt. On August 10, 1792, 9000 Parisians and National Guard troops stormed Louis' palace of the Tuileries. Louis, hating the sight of his own people's blood being shed, ordered his Swiss Guards to cease-fire. The mob massacred the guard, looted the palace, and turned Louis over to the Paris Commune who threw him into jail. The National Assembly, under heavy pressure from the *sans culottes*, agreed to new elections for a convention to form a new constitution. The monarchy was abolished and replaced by The First Republic, which would see the revolution through its trial by fire.

Louis' Flight to Varennes

Since Marie Antoinette was from Austria, Louis and his family were to travel disguised as servants of a German baroness to the Austrian Netherlands. Helping them was Count Hans Axel von Fersen, most likely the queen's lover, who arranged for a coach to help them escape. This is where things started going wrong, because Marie Antoinette insisted on a more luxurious coach so she could take the "minimum" two maidservants. They found such a coach, but it was much slower than the original one Fersen had found. Then the queen had to go shopping for new clothes and perfume, which delayed the trip even more.

They finally slipped out through an unguarded gate in the Tuileries palace and were soon rolling toward a rendezvous with a detachment of royal cavalry who would escort

them to the border. Of course, before rapid communications like the telegraph or telephone, trying to coordinate travel schedules from two distant starting points was virtually impossible. Thus, the inevitable delays occurred, with the cavalry arriving at the rendezvous point well ahead of Louis' party. The sight of a large number of cavalry just hanging around town aroused suspicion among the locals as to why they were there. They claimed they were waiting for a payroll train, but it had gone through long before. Not knowing when or even if Louis would arrive, the cavalry finally had to depart, leaving the king without protection against any random son of a postmaster armed with a portrait of the king.

That son of a postmaster was a man named Drouet who, unfortunately for Louis, was a staunch supporter of the revolution, had been to Paris to celebrate the fall of the Bastille, and therefore recognized Louis from his portrait on an *assignats* note. Just to make sure, he brought a judge who had served Louis at Versailles to positively identify him. When the judge knelt to acknowledge his king, the game was up and Louis was arrested at Varennes, just thirty miles short of his destination.

The royalist troops did come back to rescue the king, but were delayed nearly an hour when one of them fell into a hole in the forest. When they finally arrived, Drouet, backed up by a large number of national guardsmen stuck a pistol in an officer's chest, convincing the troops to surrender. (Drouet later revealed that the gun wasn't loaded.)

While it took one day to reach Varennes, it took four to return the king to Paris, as he was escorted by thousands of national guardsmen proudly showing off their prisoner. A strange funereal silence met Louis as he entered the city, indicating any previous sympathy and support he had before was now mostly gone.

On July 17, 1791 some 50,000 Parisians assembled, with 6,000 signing a petition

calling for the king's abdication. When the Marquis de Lafayette brought out the National Guard, the mob started throwing stones, and the troops opened fire, killing fifty men and women.

The Revolution was starting to eat its own children.

Louis "real" intended victim. For some reason Robespierre, the rising Jacobin and future leader during the reign of terror, was convinced that Louis' attempted flight was a plot aimed to kill him. The National Assembly wasn't convinced.

The National Assembly met in the old royal riding school with spectators perched above the speaker's platform in the center and factions of delegates arranged from most radical on the left of the platform to the most conservative on the right. This was the source of our terms right and left wing.

War and the End of the French Monarchy (1792)

The French should have known better than go to war at this time, and a few people, like Robespierre did. The French army was actually two armies poorly mashed into one. One force was the National Guard, poorly armed, led and disciplined militia with little or no military experience.

The other force was the old royalist army, whose morale and discipline had severely slipped in the past two years. Many of its officers, mostly nobles, had fled France, while those that had stayed were under constant suspicion of disloyalty. Aggravating this situation was the practice of charging generals defeated in battle with treason and executing them, not the greatest incentive for continuing with a career in the French army. Adding to

the turmoil was the fact the two parts of the army disliked and distrusted each other.

Despite these problems, war was at first greeted as an opportunity to win glory for France and its revolution, as seen by the young men below marching enthusiastically off to war. Soon, however, the realities of how poorly prepared France was for war became apparent as the French suffered a string of defeats.

The royal family did its best to undermine the revolutionary regime and war effort. Marie Antoinette wrote to her lover, Count von Fersen, asking him to stir up foreign support against the current regime, possibly the only time a queen has asked her boyfriend to declare war on her. Louis used his veto to keep his Swiss Guard, a possible source of support for the invaders, from being disbanded. Similarly, he blocked the movement of 20,000 National guardsmen for the defense of Paris. No wonder the sans culottes decided to storm his palace and overthrow him.

The icing on the cake came after another French defeat, when the Prussian Duke of Brunswick warned the French not to harm Louis or else they would suffer the direst consequences. Given the circumstances, he couldn't have been more effective in getting Louis overthrown and executed. The sans culottes struck on August 10th, 1792.

When they did attack, National Guard units supposedly defending the king had mostly left. Only the king's Swiss Guard provided significant resistance before being overrun (top picture). The mob tore up their red uniforms and made flags of them, which was the origin of red flags symbolizing revolution.

THE REIGN OF TERROR (SEPTEMBER, 1792-OCTOBER, 1795)

Events moved quickly after the fall of the monarchy and quickly got out of hand. For one thing, the weakened National Assembly, still the government until new delegates were elected for the convention, had lost most of its authority to the *sans culottes*. This, combined with growing panic and suspicion of treason with each military defeat, led to large-scale arrests of nobles and non-juring priests (those refusing to take the loyalty oath). Fear of a counter-revolution led by prison inmates triggered the September Massacres (9/2-7/1792) when armed mobs broke into jails, set up makeshift courts to condemn prisoners, and then turned them over to thugs for execution. By the time the September Massacres had swept through Paris and France, between 1200 and 1500 prisoners had been murdered. Only about a quarter of them had originally been jailed on political charges.

Symbolic of the switch from monarchy to republic was a new calendar of twelve months with three 10-day weeks each. It started with Day I, Year I (9/22/1792) and stayed in effect for ten years. This new calendar was largely an attack on the Church and symbolized the revolution's complete break with the past. However, it was quite unpopular with the mass of French people who remained devout Catholics, showing how out of touch with the feelings of most French people the radicals in Paris were becoming.

Another break with the past came with the execution of Louis, whose fate hinged on the growing struggle between the Girondins, who wanted to limit Paris' influence on the revolution, and the radical Jacobins, who supported the *sans culottes* and used them in turn for support and intimidation. The Jacobins' call for putting Louis on trial forced the Girondins into the impossible choice of either giving in to radical pressure to try him or seeming like they were defending a very unpopular king. Louis' correspondence with the enemy sealed his fate as all the delegates voted him guilty of treason, and a narrow majority voted for execution. On January 21, 1793, Louis was executed and over 1200 years of French monarchy came to an end. In the process, the Girondins were quickly losing support to the Jacobins. Mounting

problems of war, inflation, and food shortages would finish them off.

On September 20, 1792, the French Revolutionary armies won their first battle of the war at Valmy against a Prussian army largely preoccupied with the Second Partition of Poland and also ill from eating too many grapes. Inspired by this rather lackluster victory, French armies moved forward and overran Savoy, Nice, the Austrian Netherlands, and Holland. This prompted the National Convention to declare a revolutionary struggle to liberate all people from the tyranny of kings. Naturally, this alarmed kings across Europe and united them in The First Coalition to stop the French radicals. What had been a somewhat half-hearted fight of France against Austria and Prussia, now escalated into total war against practically all of Europe.

The tide of events once again quickly turned against France. Allied armies defeated the French, whose top general, Demouriez, and minister of war defected to the enemy. Meanwhile, western France was rocked by a major revolt of peasants protesting the revolution's church policies and military draft. As enemy armies closed in on France, the economy nearly collapsed. Inflation was rampant and the assignats fell to 50% of their face value. The resulting grain shortages triggered food riots in Paris by the *sans culottes* and the Jacobins, who called for strong price controls. Events were spinning out of control, and with each bit of bad news, the Girondins' position became more dangerous. Finally, on June 2, 1793, a crowd of 80,000 armed *sans culottes* and National Guardsmen overthrew the Girondins. The Jacobins took control and established a dictatorship under the Committee of Public Safety, a group of nine men whose most famous member, Robespierre, symbolized the reign of terror about to unfold.

The Jacobins had their work cut out for them. Rampant inflation and food shortages were wrecking the economy, while France was beset by revolts from within and foreign invasions from without. It was said that Paris and one-fourth of France were fighting three-fourths of France and the rest of Europe. Given these circumstances, the Jacobins assumed dictatorial powers and initiated a number of extraordinary measures to save France.

The government took control of vital resources and production of munitions to ensure adequate military supplies for its armies. Paris alone was producing 1000 muskets a day. Strict wage and price controls were imposed to stifle inflation. Massive forced loans helped finance the effort. Newspapers were strictly controlled to maintain morale. People wore wooden shoes to save leather for French soldiers' shoes. Even scientific research was directed toward the war effort as the famous chemist Lavoisier found a better formula for gunpowder.

The Revolution freed and inspired the French to create powerful new symbols and ideas, in particular nationalism. For the first time in history a people sharing the same language, culture, and government had found a unifying spirit to inspire them in the common defense of their homeland. For this was the France of the French people, not the French king, and that fact motivated the French soldiers to fight with a spirit totally lacking in mercenaries serving merely for money. Nationalism was what allowed these much larger French armies to forage, because desertion was less of a problem or threat to generals who knew their men had a cause to fight for. This, in turn, freed French armies from cumbersome supply lines, making them more mobile despite their numbers.

Probably the most significant changes came in the military realm (covered in FC.105D). For one thing, the crisis of the Revolution forced the Jacobins to institute a universal draft of unmarried men for the army, while married men produced and transported weapons and women made tents and uniforms. This created a huge army compared to the relatively small and expensive mercenary armies that other countries fielded.

However, the draft had importance for French armies that went far beyond numbers. For one thing, the recruits were too numerous and too quickly mobilized to be trained with the strict mechanical discipline and precision of professional armies. Similarly, the huge size of these new armies also complicated the task of supplying them.

Luckily, the powerful new ideas of the Revolution, especially nationalism, meant soldiers were fighting for their own homeland and were less prone to desertion as a result. Therefore, they could be trusted to forage for supplies and return to

camp. This reduced the need for supply lines and increased the speed and mobility of French armies.

French officers, many of whom had been junior officers that had risen through the ranks to command positions left vacant when noble officers had fled France, also had to come up with innovative new tactics and formations to make optimal use of the large armies they commanded. Therefore, they used massed firepower and charging in blocks or columns of men through strategic points of the enemy line. Together, the mobility, new tactics, and spirit of nationalism saved France from the armies of the First Coalition.

Not surprisingly the strict repressive measures used by the Committee of Public Safety were unpopular and met heavy resistance, especially outside of Paris. Therefore, the Jacobins launched the famous Reign of Terror. Special officials, known as Representatives on Mission, went to the army and provinces to maintain the war effort and enforce the government's will with deadly efficiency and the guillotine. They raised money, seized supplies for the army, drafted recruits, cleaned up the army and local governments, crushed revolts, and killed anyone who got in their way. (An estimated 500,000 people died in the Vendean uprising in western France.) Paris especially suffered from the Terror since the Jacobins were caught in a vicious cycle. The more enemies they killed, the more reprisals from the victims' friends and families they feared. This inspired more executions, more fear, and so on. As one observer watching the Jacobins turn on their former allies and devoted revolutionaries put it, the revolution was eating its own children.

Vendean rebels surrender to government forces. Ironically, the biggest issue causing revolts, the draft, also led to their defeat, since few wanted to fight, especially outside their home districts.

By the summer of 1794, the Committee of Public Safety's drastic measures had accomplished their purpose. They had suppressed the revolts, stabilized the economy, and secured France's borders. To many, the end of the crisis should have signaled the end of the government's repressive measures. But the Jacobins were caught up in their own cycle of repression and paranoia that merely intensified the Reign of Terror. Nearly 1400 people fell victim to the guillotine in Paris alone between June and July 1794. The Jacobins, increasingly out of touch with the feelings of most French people outside of Paris, shut down churches or turned them into "temples of reason" for their new Deistic style religion, the Cult of the Supreme Being. Growing fear and dissatisfaction with the Committee of Public Safety's Republic of Virtue finally led to a conspiracy known as the Thermidorean Reaction, which ousted Robespierre and his colleagues (7/28/1794).

The revolution now started to wind down, but its effects did not. The results of the French Revolution can be summarized by the revolutionary motto: "liberty, equality, and brotherhood." Briefly put, liberty referred to the right of all men to live freely with certain guaranteed rights such as free speech and religion. Equality referred to the equality of all men before the law as opposed to the inequities of the old feudal system that the revolution had swept away. Brotherhood (nationalism) referred to the right of a people united by a common language and culture to be autonomous and live under its own laws and government.

In October 1795, a new constitution and government, the Directory, took over, but not without incident. An uprising against the new government threatened it before it even took over. A young artillery officer, Napoleon Bonaparte, was called in to save the day. With his famous "whiff of grapeshot," he saved the new government and launched his own career, which would spread French power across the continent. French power would not last, but the seeds of the revolution's liberal and nationalist ideals that were planted in the process would take root and transform the face of Europe and eventually the world.

The September Massacres (Sept., 1792)

The September Massacres started when a crowd stopped six carriages carrying thirty non-juring priests to prison, hauled them all out and killed them on the spot. Then they started pulling prisoners out of the jail and executing them after quick judgments that were supposed to resemble trials. From September 2nd to 6th, between 1247 & 1368 prisoners were killed this way.

These executions were certainly a brutal event, but they need to be put into context. Despite the Duke of Brunswick's warning that the French would pay dearly for harming the king, they had done just that by storming his palace and locking him up. One can imagine the growing fear as the French army went down in defeat and disintegrated while enemy forces were closing in on Paris. Besides the enemies without, there were also potential enemies within, namely nobles and clergy who opposed the revolution. Thus it was fear, more than brutish human nature, which drove the violence.

Not that there weren't atrocities, such as that told of one executioner who, after withdrawing his sword from a prisoner's chest, reached into the wound, tore out the heart, and put it in his mouth as if to eat it while the crowd cheered him on. Similar scenes reportedly took place during the Cultural Revolution in China in the 1960s.

However, the violence was not totally indiscriminate. The mob did focus on clergy and nobles who were seen as likely collaborators with the enemy. Therefore, the debtors' prison was left alone. There were even trials, of a sort, and some people were even acquitted.

Showing Revolutionary Spirit

A revolutionary clock
converting the day to 10 hours

Revolutionary spirit was displayed in all sorts of ways. Revolutionaries replaced kings, queens, and jacks with revolutionary virtues on playing cards. Parents would name their children after Greek and Roman heroes, while more radical revolutionaries named boys Squitch, Duck, and Dandelion in honor of the peasantry. Girls were named Cow, Carrot, and Rhubarb. There was even serious discussion of legislating the informal use of *tu* (you) in conversation instead of the formal *vous* typically associated with the upper classes.

Metric time. The Revolution's metric calendar also had 10-hour days with minutes and seconds in multiples of 10. There was even a decimal clock in the Convention. At first the days of the week were named after plants, animals, and tools. They were later replaced with numbers.

A close shave. Sometimes, it's the little irritations in life that especially touch us off, such as a scratchy beard. Traditionally, peasants would shave on Sunday, their one free day of the week. However, with the new 10-day decades (i.e., weeks) they only shaved once every 10 days, giving their beards three more days to grow to that scratchy, irritating phase, a constant reminder of another reason to hate the revolution.

The End of the Royal Family (1793)

Louis' trial and execution. Unfortunately for Louis, his enemies did find incriminating correspondence with Austria, leading to his conviction by a vote of 693 to 0. The vote condemning him to death was much closer, with 361 voting for immediate execution, 288 for another sort of punishment, such as prison or exile, and 72 for death, but with a number of reservations or conditions that would delay his fate. On January 21, 1793 Louis was executed and France turned its back on 1200 years of history and a political order that many still believed was divinely ordained. As one person put it: "On that day, everyone walked slowly, and we hardly dared look at one another."

Marie Antoinette met her fate nine months later. Her trial was a grueling 16-hour affair with the foregone conclusion of guilt all along. The main charge was conspiring with foreign powers (which she did), but also committing incest with her 8-year old son (which is less likely).

Getting on the cart that would take her to the guillotine, she remarked how shabby it was, apparently having learned nothing about choosing vehicles since the Varennes episode. Before burying her, the gravediggers took a lunch break, giving Madame Tussaud a chance to do a wax sculpture of her head for her wax museum.

The young royal prince, Louis, would meet an even crueler fate, being beaten to death by his jail-keeper, Simon the Cobbler.

Building a Revolutionary Army

Real Sans Culottes. In 1793 the war effort was faltering badly. Thousands of volunteers, disillusioned by the war, quit after serving their first term, and the French armies dropped from 400,000 to 225,000 men. One problem plaguing morale was an unfair draft that favored the rich who could buy replacements for themselves. The troops were also poorly fed and equipped, many without boots, and some even without pants, having to pin cloaks around themselves. As the radical leader, Georges Jacques Danton, put it upon seeing such soldiers: "Those are real Sans Culottes."

Corruption also hampered the war effort. While civilians wore wooden shoes to save leather for the soldiers' shoes, corrupt contractors used paper for the soles of soldiers' shoes, which wore out almost immediately. Shoemakers then did not differentiate between right and left shoes.

Lazare Carnot (below) was the minister of war whose administrative abilities organized the French revolutionary army into the most effective fighting force of its time. Thanks to his efforts and the Jacobins' drastic measures, the French army grew to 800,000 men.

The Amalgame. In 1793, Carnot instituted a system known as the Amalgame, where one old royalist battalion (below left) and two National Guard battalions were combined to make up one regiment. The principle of promotion by merit along with combining experienced troops with less trained ones rapidly trained and developed the French army into Europe's best fighting force.

Cleaning house. At the battle of Hondschoote near Dunkirk (9/8/93), the French general, Houchard proposed retreat, but the Jacobins' Representative on Mission ordered attack and the French won. Houchard and 22 other (mostly noble) officers were then executed for treason. Incidents like this cleared the way for younger officers with new ideas.

Democratization of the ranks. Not every radical reform tried by the Revolution worked, however. Backed by government representatives, troops were encouraged to disobey their officers, with predictably disastrous results. Adding to the chaos was the fact that from 1793-4 the Jacobin government executed 84 generals and dismissed 352 more. By the end of, 1793, nobles made up only 3% of the officer corp. The average age of new generals in the 1790s was just thirty-three.

Cold steel to the extreme. As the French adopted more massed infantry tactics, the minister of war, Joseph Servan de Gerby, had nearly half a million pikes produced for the army. Luckily for the French, the Generals thought the combined firepower and thrust of the musket and bayonet were superior to only pikes.

The Death of Marat

The incident touching off the Terror was the murder of the popular Jacobin leader, Jean-Paul Marat, by the Girondin sympathizer, Charlotte Corday (below). The anger this aroused among the Sans Culottes allowed the Jacobins to seize control of the Committee of Public Safety and institute the Reign of Terror against their enemies. Marat's death was immortalized in a famous painting by Jacques Louis David (above).

Agents of the Terror

In the first months of Jacobin rule, representatives on mission were virtually unrestrained in their use of power, leading to some of the worst atrocities associated with the Terror. In the early months of 1794, the most notorious of the representatives were recalled to Paris. Following are some of the more notorious representatives of mission and their accomplishments:

- Joseph le Bon, when told he was being too merciful for Committee of Public Safety's tastes, "shortened" 542 people in the following weeks. Supposedly, he would mimic the expressions of guillotined victims to amuse his wife at dinner. He himself was "cut short" in 1795
- Jean Baptiste Carrier, considering trials a waste of time, bound prisoners' hands and loaded them onto barges, which he then sank in the Loire R. In four months he disposed of 4000 "undesirables" this way.
- Joseph Fouché, sent to Lyons which had rebelled and been retaken, began a program of vengeance with a mock religious ritual led by a donkey wearing a bishop's mitre and dragging a Bible and crucifix tied to its tail. Fouché then started lining criminals up in front of trenches and mowing them down with cannon fire.

After several hundred of these, he resorted to the more leisurely guillotine. He also defaced the cathedral and destroyed hundreds of beautiful homes in Lyons, which he renamed The Liberated City. Robespierre recalled Fouché for being too brutal, but he escaped punishment, later becoming Napoleon's Minister of Police where he could do some real damage.

A New Religion for the Republic of Virtue

Inspired by such men as the fanatical ex-priest, Joseph Fouché, the Hébertists, a group even more radical than the Jacobins, tried to replace Christianity with their own quasi-Deistic religion called the Cult of Reason, which saw Nature as the priest of the Supreme Being, the universe as his temple and virtue as his worship. They even briefly closed the Catholic Church, putting signs over cemeteries declaring, "Death is an eternal sleep."

The primary purpose of this cult was to provide a moral basis for the utopian Republic of Virtue that was to replace the decadent values of the old regime. Much like the Bolsheviks during the Russian Revolution in 1917, the goal was to create a whole new man as well as world. The logic reconciling the Republic of Virtue with the Reign of Terror was that, if the basis of popular government in times of peace is virtue, in times of revolution, it is virtue and terror. For terror without virtue is tyranny, while virtue without terror is powerless and disastrous.

Figuring the masses would need some sort of visible icon to relate to, they created a Goddess of Reason, portrayed by a live woman to avoid the appearance of idolatry. It was done largely in the hope it could replace the Virgin Mary in people's hearts. It didn't.

Not surprisingly, the Cult of Reason gained little popular support and Robespierre was shocked by its atheistic slant. Therefore, he modified it into the Cult of the Supreme Being, which believed in a more active god and the immortality of the soul, making it a bit less out of touch with popular Catholic beliefs.

Robespierre described the Supreme Being as follows: “He did not create kings to devour the human race. He did not create priests to harness us, like vile animals, to the chariots of kings and to give to the world examples of baseness, pride, perfidy, avarice, debauchery, and falsehood. He created the universe to proclaim His power. He created men to help each other, to love each other mutually, and to attain to happiness by the way of virtue.”

Inaugurating this cult in June 1794 was the Festival of the Supreme Being (above), an event designed by the artist, Jacques-Louis David who even had a fake mountain built for it. After a chorus of blind children sang a hymn to divinity, an effigy of Atheism was burned, only to have a monument to wisdom emerge from its ashes.

Mimicking the Christian Sabbath, the Cult was to be commemorated at the end of each 10-day decade in the revolutionary calendar. Instead of baptizing their children in the name of the Father, Son, and Holy Ghost, many French baptized them in the name of “Liberty, Equality, and Brotherhood,” the motto of the revolution. Other religions were also outlawed, a violation of the principle of freedom of religion, which contributed to the eventual fall of Robespierre and the Jacobins and immediate repudiation of the Cult.

Thermidor and its aftermath (1794-5)

Robespierre who led the Jacobins and the Committee of Public Safety during the Terror. Like Cromwell and Lenin in their respective revolutions, he was a man of simple, almost Spartan, tastes, but a fanatical ideologue, concerned only with carrying out the revolution, no matter what the cost.

The flurry of executions at the height of the Terror claimed some of the revolution’s most illustrious leaders, including the radical leaders Georges-Jacques Danton and Camille Desmoulins. Danton, an extremely popular leader whose face had been trampled by pigs as a child, offered such a powerful and eloquent defense that he could be heard across Seine. Afraid of the trouble he might stir up, the Jacobins had him silenced and quickly executed.

By late July 1794, only 117 of the original 750 members of Convention still attended, the rest either being killed, in hiding, having fled Paris or just avoiding meetings of the Convention. People in general stopped attending executions (normally a popular public entertainment) since they were so commonplace. Similarly, Paris’ social life nearly died as well, since people were afraid of being seen in the wrong place at the wrong time, wherever and whatever that might be that week. A cartoon satirizing the indiscriminate violence of the Terror by showed a forest of guillotines with Robespierre finishing off the only potential victim left, the executioner.

Therefore, when Robespierre left town for a few days, members of the Convention formed a plot to overthrow him and the Jacobins. On July 27, 1794 (Thermidor by the revolutionary calendar) they struck. Robespierre’s right-hand man, Louis de Saint-Just, the so-called Angel of Death was giving a speech when the conspirators pushed him from the podium, denounced Robespierre and called for his arrest. Robespierre and his cohorts fled to the Hotel de Ville where he was arrested. There is still a dispute about whether Robespierre’s shattered jaw (below) came at the hands of the conspirators or from a botched suicide attempt that night. Being declared an outlaw, he was

executed without trial the next day along with 21 of his associates. The Reign of Terror had finally ended in what has been known ever since as the Thermidorean Reaction.

The Thermidorean Reaction led to a more widespread reaction called the "White Terror" where Muscadin, gangs of richer youths armed with metal canes, attacked Jacobins in the street. Meanwhile, in the countryside fanatical gangs calling themselves the "Companions of Jesus" massacred any Jacobins they could find. Much like the September Massacres, they would also empty prisons of suspected terrorists and execute them.

Luckily for France, the war effort was going well, with Prussia and Spain making peace and Holland surrendering in 1795, leaving only Britain and Austria from the First Coalition still fighting France. The aftermath of Thermidor also saw the tight restrictions of Jacobin rule ended and the return of personal liberties. However, this also allowed the return of inflation and financial turmoil. Finally, in October 1795, three years after forming the Convention, a new government, the Directory, took power. Even this transition to power was violent, as a royalist insurrection leading 25,000 people threatened to topple the new government before it even took over. The leaders of the Directory turned to a young artillery officer, Napoleon Bonaparte, who mowed down 2-300 of the rebels and scattered the rest with a "whiff of grapeshot."

No one realized it then, but the future would belong to this young artillery officer.

THE RESULTS OF THE FRENCH REVOLUTION

Although it would take until 1871 for the French Revolution to play out, it was triggering profound effects in France and the rest of Europe as early as 1789. One touchstone by which to analyze the Revolution's results is its motto: "Liberty, Equality, and Brotherhood. The power of these three ideas would quickly spread to the rest of Europe, especially after Napoleon's final defeat in 1815, and eventually across the globe.

Liberty refers to the basic civil rights we often take for granted as being the natural rights of people everywhere, such as speech, press, assembly, religion, and voting for officials and laws, etc. The last of these, voting, was typically among the last to be extended to all members of society, in particular women.

Equality meant that everyone should be equal before the law, rather than face unjust double standards. At times, some of the more subtle effects of such an idea can magnify across history. This was especially the case with inheritance law in France. Since all men were seen as equal before the law, primogeniture was outlawed, giving all sons equal shares of an inheritance, and even daughters a portion, although less than the sons got. The problem with splitting up family lands into several smaller plots was that repeatedly dividing it into ever-smaller plots would make it impossible for all the heirs to support their families. Therefore, French peasants in the 1800s had a lower birthrate to avoid splitting family lands. This, however, reverberated over the following century in several ways. For one thing, few French people emigrated to places like the Americas compared to other European peoples. Likewise, there were fewer people available for factory work, which slowed France's rate of industrialization. Also, the unification of Germany in 1870 prompted rapid industrialization and population growth that rapidly passed up France in both categories. By 1900 this would generate mounting worries in France about the growing threat of Germany that would help lead to World War I.

Brotherhood (AKA nationalism) was the idea that a people united by a common language; history, culture and geography should have the sovereign

right to choose their own destiny. This would also prove a mixed blessing. On the plus side, nationalism included everyone sharing the traits just mentioned, bringing them into both a larger and more cohesive group. However, it also tended to exclude people not sharing the same nationalistic traits.

Another good news/bad news aspect of nationalism was the competition of the nation state with older institutions, in particular the family and religion, for the loyalty of its citizens. While some argued legalizing divorce and implementing civil marriages and mandatory public education helped nations get past some of the more regressive attitudes and narrow loyalties of the family and religion, the state has had difficulty adequately replacing those institutions in terms of moral and ethical education, social stability, and providing social services that used to be the task of church and family.

Nationalism, by weakening the bonds and influence of family religion, has often been blamed for both domestic and foreign problems. Domestically, many would say the nation state has contributed to rising crime rates and social misbehavior. In foreign affairs, nationalism's exclusive nature has helped create, especially through public education, a sense of superiority over other nations, who reciprocate with their own feelings of superiority. By 1914 such attitudes would raise international tensions in Europe to levels that would trigger two disastrous world wars in the twentieth century.

NAPOLEON AND HIS IMPACT (1799-1815)

Few men have dominated an age so thoroughly as Napoleon Bonaparte dominated his. In many ways he was like Adolph Hitler: charismatic, a master psychologist and politician, and ambitious to the point of self-destruction. Both started wars that led to vast destruction and a new political order. Both men shaped their times, but both were also products of their times who went with the currents of their respective histories and adeptly diverted those currents to suit their own needs. And ultimately, both were dismal failures.

To a large extent, Napoleon's career was a result of the military and political forces he inherited from the Revolution and exploited for his own purposes. In military affairs, he was lucky to inherit the military innovations of the French Revolution, such as mass conscription which made possible the use of block tactics in order to attack in column and eliminated the need for supply lines, thus making French armies much more mobile. Therefore, the two characteristics of Napoleonic warfare, massed firepower and mobility were already present when he started his career. However, it was Napoleon's genius that knew how to use them effectively.

Politically, France had suffered a full decade of revolutionary turmoil by 1799, making the government unstable and corrupt. Church policies were unpopular, especially since they had triggered rampant inflation. People longed for a more political stability and secure lives. Therefore, the interplay of military innovations that made Napoleon a national hero and the secure government he promised allowed him to seize power in 1799. Further military victories, once again against the Austrians in Italy helped him consolidate his hold on power and declare himself emperor of France in 1804.

While we mainly think of Napoleon as a general, he was also a very active administrator whose internal reforms both consolidated some accomplishments of the French Revolution and suppressed others. One way to assess his government of France is to see how it conformed to the revolutionary motto: "Liberty, fraternity (i.e., nationalism), and equality". As far as political and civil liberties were concerned, Napoleon largely

suppressed them with strict censorship and the establishment of a virtual police state in order to protect his power.

However, he saw equality as a politically useful concept that he could maintain with little threat to his position. After all, everyone, at least all men, were equally under his power. Furthermore, he codified France's laws, which made men equal under the law while maintaining their legal power over women. Therefore, any hopes women may have had of the Revolution improving their legal position were thwarted by Napoleon.

Napoleon saw nationalism as indispensable to maintaining the loyalty of the French people to his regime. After all, it was the spirit of nationalism that had inspired its armies in a remarkable series of victories that had especially benefited Napoleon and allowed his rise to power. The trick was for Napoleon to build a personality cult around himself so that the French people would identify him with France itself and therefore make loyalty to him equivalent to loyalty to France. However, by identifying national loyalty with one man, Napoleon inadvertently weakened the inspirational force of nationalism and thus his own power.

Napoleon's internal policies strengthened France and allowed it to dominate most of Europe after a series of successful military campaigns (1805-7). Naturally, he established French law and government in the countries he overran, mistakenly thinking the administrative and legal reforms of the revolution could be separated from the ideas of Nationalism and Liberalism (liberty and equality) that had given those reforms life and substance. Therefore, Napoleon's imperial rule inadvertently spread these ideas of Nationalism and Liberalism.

This had three effects, all of which combined to overthrow Napoleon. First, the empire's non-French subjects picked up the ideas of Nationalism and Liberalism and used them to overthrow, not support, French rule. Second, subject rulers adopted French military and administrative reforms to overthrow French rule.

Finally, Napoleon's power and success up until 1808 apparently blinded him to his own limitations. Therefore, he got involved in a long drawn out war in Spain (1808-14) and launched a disastrous

invasion of Russia (1812). This led to the formation of a new coalition that finally defeated and overthrew him in 1815. The victors met at the Congress of Vienna, hoping to restore the old order as it had existed before the Revolution.

However, despite his intentions, Napoleon had effectively planted the seeds of Nationalism and Liberalism across Europe, and these ideas would spread in new waves of revolution by mid-century. Europeans would take these ideas, along with the powerful new technologies unleashed by the Industrial Revolution, to establish colonies across the globe by 1900. Ironically, these European powers, like Napoleon, would fall victim to the force of these ideas when their subjects would use them in their own wars of liberation after World War II.

Napoleon's Elephant of Revolutionary Oblivion

Even a dictator as shameless as Napoleon realized he had to pay the French Revolution its due. To that end while also commemorating his own victories and obliterating any lingering ideas about the superiority of democracy, he decided to build a great elephant on the site of the Bastille. Why he chose an elephant isn't quite clear, but he intended it to be cast in bronze and be big enough for visitors to climb an interior staircase to a tower on its back, (Maybe its trunk could serve as a slide back down.) However, Napoleon's wars co-opted the bronze for the statue to make cannons and the elephant was cast in plaster. After Napoleon's empire collapsed, the Elephant of the Bastille was left to rot, becoming overgrown and infested with rats and other sorts of vermin. Despite petitions for its removal, it remained in place until 1846, when its tattered remnants were finally removed.

Film note: Napoleon's elephant is a major background prop in the film *Les Misérables*.

THE RISE OF NAPOLEON (1795-1804)

"Clear policy consists of making nations believe they are free."-- Napoleon

Napoleon's career largely resulted from the military innovations he inherited from the French Revolution, such as mass conscription which made possible the use of block tactics in order to attack in column and eliminated the need for supply lines, thus making French armies much more mobile. The Revolution also provided him with young officers who had largely developed these new tactics and were willing and able to successfully implement them on the battlefield. Therefore, the two characteristics of Napoleonic warfare, massed firepower and mobility were already present when he started his career.

Napoleon Bonaparte himself was barely French, his homeland Corsica having just become part of France two years before his birth in 1769. He attended a French military school and, while not a great student, picked things up quickly and finished a three-year program in one year. His Corsican accent and wild appearance set him apart from his classmates. Although sociable, he liked to be alone a lot. At an early age he exhibited the qualities that would earn him and France an empire: remarkable intellect, puritanical self discipline, a virtually inexhaustible energy level, and a willingness to plan things out in such detail as to leave nothing to chance. He admired Caesar, Alexander and Charlemagne and, like them, exhibited the quick decisive manner that made them all great leaders.

At age sixteen, Napoleon became a second lieutenant in the royal artillery, but his non-noble and Corsican origins left him little chance of promotion. All that changed with the French Revolution. In 1789, he went back to Corsica to fight for its independence. After quarrelling with the leader of the revolt, he returned to France and joined the Jacobins. In 1793, the young Bonaparte became a national hero by leading the recapture of the French port of Toulon from the British. The next year Napoleon's ties with the Jacobins and their fall in the Thermidorean Reaction landed him in jail for several months.

It was in 1795 that Napoleon got his big break when his famous "whiff of grapeshot" mowed down rebels in the streets of Paris and saved the new government, the Directory, from counter-revolution. This event catapulted Napoleon into the command of the Army of Italy, a ragtag army without enough shoes or even pants for its men. Nevertheless, he led this army against the Austrians in a lightning campaign that showed all the hallmarks of Napoleonic generalship: rapid movement, the ability to outnumber the enemy at strategic points with men and massed firepower, and a knack for doing the unexpected to keep his enemy constantly off balance. Napoleon drove with characteristic speed through northern Italy and then into Austria, forcing it to sign the Treaty of Campo Formio. However, this victory and the prospect of renewed French offensives alarmed kings all over Europe who formed the Second Coalition of Britain, Austria, Prussia, and Russia against France.

Napoleon saw Britain as his main enemy, because it funded France's other enemies and also had a powerful navy protecting its coasts. As a result, Napoleon came up with a bold, if ill conceived, plan: conquer Egypt and use it as a stepping-stone to invade British-held India. At first, all went well. Napoleon's fleet eluded the great British admiral, Lord Nelson and landed in Egypt in 1798. The French decisively beat the Mamluke army and soon ruled Egypt. Then things fell apart. Lord Nelson found the French fleet and demolished it in the Battle of the Nile, thus stranding the French army in Egypt. Napoleon tried a daring march to Istanbul by way of Syria, but his artillery was captured and he had to return to Egypt with his sick and demoralized army. While the French languished in Egypt, Napoleon got word of political turmoil in France. He thereby abandoned his army (which later surrendered to the British) and slipped across to France. He then took part in a daring plot to overthrow the government. The conspiracy succeeded and Napoleon became First Consul of France in 1799.

Consolidating his power. The government that Napoleon and his allies set up, the Consulate, was a mockery of democracy and aptly reflected the above quotation. People elected delegates who chose other delegates who chose other delegates from whom were appointed legislators who had no power anyway. So much for the legislature. As for

Napoleon's fellow conspirators, Ducos and Sieyes, they were shoved into the background and forgotten within a month, leaving Napoleon firmly in charge of France. However, his position was far from secure, because France was still ringed by the Second Coalition.

Napoleon first attacked Austrian forces in northern Italy, which he barely defeated at the Battle of Marengo (1800). This victory allowed Napoleon to return to France in triumph and further consolidate his position there. Meanwhile, his generals finished up the war against Austria, taking the Austrian Netherlands, northern Italy, and the left bank of the Rhine for France.

That left Britain to face France. Since Britain's navy and France's army were virtually unbeatable by the other side, and several neutral nations including the United States and Sweden had armed themselves against both Britain and France, the two big powers made peace in 1802. Prussia and Russia soon followed suit. Peace settled over Europe, at least temporarily.

Napoleon next turned his attention to Germany in order to settle a number of land disputes. Germany was still a patchwork of secular principalities, free cities, and church states. Since the Church tended to favor Catholic Austria against revolutionary France, Napoleon eliminated all but one church state and 44 out of 50 free cities, giving their lands to various German princes who now saw Napoleon as their benefactor.

Having fought his enemies to a standstill and made France the most feared and respected power in Europe, Napoleon could now pursue his next goal: becoming emperor of France. This was a tricky situation, since the French people might not take kindly to getting a new king so soon after getting rid of the old one. Using the title of emperor rather than king would partly ease people's misgivings and also give them a sense of France's imperial superiority over the rest of Europe. Napoleon approached the title in stages, first getting himself elected consul for ten years, then for life, and then, after a fake assassination plot to make people realize how much they loved him, emperor.

The coronation in 1804 was a splendid affair with even the pope coming to crown Napoleon.

(Napoleon actually decided to crown himself and just let the pope watch.) The next day the emperor gave bronze eagles to his regiments as standards reminiscent of the Roman Empire. He even created a new nobility of dukes and counts from his officers in order to make a court that rivaled the splendor of other European courts.

The Napoleonic state. While Napoleon is mainly remembered for his military campaigns and conquests, much of his importance lies in his government of France and how it consolidated the gains of the Revolution. For one thing, he kept the Revolution's administrative reform of dividing France into 83 *departements* whose governors (*prefects*) he appointed centrally. He centralized the tax system (still used today) and established the Bank of France to stabilize the economy of France. The Revolution's system of free but mandatory education was kept and expanded with military uniforms and discipline being imposed. Napoleon also consolidated many of the Revolution's social and legal advances into five law codes. His civil code maintained the equality of all men before the law, but reasserted the power of the husband over the wife, thus negating some of the influence women had exerted during the Revolution.

Although not a religious man, Napoleon recognized the attachment of most French people to the Catholic Church and how the Revolution's policies against the Church had caused discontent and revolts. Therefore, in 1801 he made peace with the Church, recognizing it as the religion of the majority of Frenchmen and giving the clergy the right to practice their religion within the "police regulations" of France. Those regulations kept confiscated Church lands for the state and still paid the clergy their salaries. Regardless of that, Napoleon gained a great deal of popularity through his Church policy without giving up anything of essence.

Napoleon may have consolidated some gains of the Revolution, but he repressed others, for his "police regulations" in many ways amounted to a police state. Such civil rights as freedom of speech and press were now things of the past as 62 of 73 newspapers were repressed, and all plays, posters, and public conversations had to meet strict standards of what Napoleon thought was proper. Enforcing all this was Napoleon's minister of

police, Joseph Fouche, formerly one of the Jacobins' representatives on mission during the Terror. He was a slippery character who had survived the Thermidorean Reaction and attached his fortunes to those of Napoleon. Fouche's spy network (one of four in France) kept him informed on just about everyone of importance in France (including Napoleon's own personal life). Fouche himself claimed that wherever three or more people were talking, one of them was reporting to him. By 1814 he had an estimated 2500 political prisoners locked away. Napoleonic rule certainly had its darker side.

Napoleon's Character

The earliest known portrait of Napoleon (1785)

Corsica was a rough mountainous island constantly beset by family feuds. Until a year before Napoleon's birth, it was under Genoese rule. However, a rebellion on the island (supported by Napoleon's father) was too much for Genoa to handle, so it sold Corsica to France in 1768. Thus, Napoleon, who was born the next year, was barely French.

The Loner. Being in essence a foreigner (Italian) at Brienne Military Academy probably set him apart from the French nobles' sons at the school. That and a basically solitary nature caused him to keep to himself. He graduated from a three-year program in one year, forty-fourth in a class of fifty-two.

Napoleon had a seemingly inexhaustible level of energy, going on just a few hours of sleep a night and getting up to a steaming hot bath. He also had a lot of nervous energy, habitually carving away at furniture while dictating. (His mother must have sent him outside to play a lot.)

He also had remarkable intelligence and powers of concentration. He could dictate five or six letters simultaneously for eight or nine hours straight. Of course, this was before the invention

of the ballpoint pen, so taking dictation involved a lot of sharpening one's quill and dipping in ink. Therefore, Napoleon would dictate part of letter one, and while that secretary was catching up, dictate part of letter two, then three, four and five. By that time, secretary one had caught up and Napoleon would pick up his train of thought for that letter and dictate a bit more, go on to letter two, and so on until all the letters were finished. He probably spent more time as an administrator than general, dictating between 54,000 and 70,000 letters in his lifetime. He himself admitted that he probably worked his main secretary, Meneval, to death.

Added to these qualities were a puritanical self-discipline and drive to plan out each battle in meticulous detail. As he himself put it: "Every operation must be done according to a system because chance cannot bring success."

Concerning his belief in luck he said: "Is it because they are lucky that great men become great? No, but being great, they have been able to master luck." Napoleon said his preparation for battle was like a woman in labor, although there are no reliable accounts of him actually giving birth.

Napoleonic warfare

It's not surprising that the first of the great modern revolutions would produce the first great modern general. Or, more properly, we should say generals, because Napoleon inherited the military reforms pioneered by preceding generals during the Revolution and relied on other brilliant generals to carry out his orders successfully. However, there were several qualities that distinguished him in particular.

1) The use of quickness and mobility over precise maneuvers was a concept developed during the Revolution when the huge numbers of raw recruits complicated the task of supplying and training French armies, leading respectively to foraging, which increased mobility, and looser formations that required less precision in the ranks. Mobility and massed formations are two qualities rarely combined in armies. Napoleon took these qualities and further perfected them. Key to this was his uncanny ability to figure out

the number of marches it took to concentrate all his forces at one point.

2) The use of massed firepower from artillery just added to the potency of Napoleon's armies. Keep in mind that he started his career as an artillery officer, and the value of cannons never left his consciousness. Crucial to this was the development of lighter field artillery before the Revolution, thus making massed cannon fire on battlefield possible.

When he invaded Russia in 1812, Napoleon took 1000 artillery with him. Many of those cannon barrels, captured by the Russians, can be seen piled up in the Kremlin.

3) The army corps system may have been Napoleon's most important innovation, although it also drew upon ideas put forth since the Seven Years War. Since the armies were so large Napoleon divided them into separate corps, each of which was a self-contained army with its own infantry, cavalry, artillery, and logistics services. Army corps would advance separately along a parallel path and within one or two days march from one another, allowing them to quickly concentrate upon one point of attack.

Spreading out like this allowed the army to feed more effectively off the land and enhanced the army's mobility. It also created a front up to 130 miles across, thus confusing the enemy as to where the main attack would concentrate. To further confuse the enemy, the French used a large screen of cavalry in front of the army mask its movements. Thus opposing leaders would be forced to scatter their forces to meet any possible attack, thus giving the French the element of surprise.

In the first illustration, an army moves in separate corps no more than one day's march

apart. A cavalry screen precedes it to mask its movement and locate the enemy.

In the 2nd illustration, the enemy has been located & the various corps converge to envelop it.

A corps was designed to hold off an enemy attack until the rest of the army to come to its rescue. Its commander had general orders for advancing, but was left a lot of autonomy in handling his corps as different situations arose. Thus the effective functioning of this system required excellent officers, such as the French Revolution had supplied and Napoleon made use of in his early career before they were largely killed off.

Napoleonic Censorship and Propaganda

One modern aspect of Napoleon's dictatorship was his use of censorship and propaganda. Since he couldn't control everything said in Paris' 73 different newspapers, he shut all but 11 of them down. As for any remaining newspapers, books, and other public media, Napoleon expected the following from his censor, Citizen Ripault:

- A daily report of all articles that might affect public opinion
- Analysis every 10 days of all books and pamphlets bearing on moral or political questions
- Similar analysis of any play within 48 hours of production
- Similar analysis of all bills, posters, advertisements and public conversations

One mass medium he especially exploited for propaganda purposes was the striking of a continuous series of medals commemorating his victories. Starting with his first victory in Italy in 1796, where he portrayed himself as Hercules fighting the many-headed hydra (above), Napoleon progressively positioned himself in the public mind as France's greatest hero and the one man who could win military victories, thus setting up the coup where he seized power in 1799.

Interestingly, Napoleon even struck medals commemorating his defeats. Of course, this gave him the opportunity to give his version of those setbacks. For example, one medallion (below) portrays his defeat in Russia as purely the result of natural forces beyond his control (i.e., the Russian winter), showing Boreas the North Wind as the real culprit. Similarly, he explains/excuses his fall from power in 1814 as the result of “adverse fortune” turning her back on him, not any mistakes he might have made.

Public education was another important aspect of information control. In 1807-08, French schools were reorganized under the central authority of the University of France (i.e. the state). As Napoleon put it: "There will be no political stability so long as there is no teaching body based on stable principles. So long as children are not taught whether they must be Republicans or Monarchists, Catholics or Free Thinkers, and so on, that State will not constitute a nation, but rest on vague and shifting foundations, ever exposed to disorder and change.

While the Church did not determine curriculum, Napoleon did have a place for the clergy in his schools: to keep children in line by instilling in them the fear of God. Therefore, religion was a basic feature of public education and the cornerstone of religion was Napoleon's catechism for all French children.

Consider the following question and answer from that catechism:

"Question: What should one think of those who fail in their duties to our emperor?"

Answer: According to the apostle, Saint Paul, they would resist the order established by God Himself and would make themselves deserving of eternal damnation."

Napoleonic Trivia

The real ride across the Alps. While David's famous painting shows Napoleon crossing the Alps on stallion rearing up on its hind legs precariously close to a dropoff, the real crossing was a bit less heroic. Instead of a horse, Napoleon rode a more sure-footed mule.

"The Little Corporal" was a nickname Napoleon earned in the middle of the battle of Lodi (1796), when he dismounted to lay some artillery pieces to cover the French assault over the river, a job that corporals usually performed. On the 2nd day of the Battle of Arcola (11/15-17/1796), Napoleon supposedly seized a standard and led an assault across a bridge, thus adding to his legend. In addition, he knew thousands of his troops by name, which helped his popularity with the army. Even more important, he was a winner, and soldiers love to follow a winner.

Grapeshot was a particularly nasty anti-personnel weapon fired from cannons, consisting of a container, such as a canvas bag, full of pellets. It was shot to land in front of enemy troops where it would break open and spray its victims with the pellets, much like buckshot.

Battlefield urinals. In the heat of battle, a musket could heat up from constant firing to the point it would detonate in a soldier's face before he could fire it. In order to cool it down and keep it from exploding, a soldier would urinate down the barrel. Another good reason to stay hydrated in addition to all the parched throats from the smoke of musket fire.

General mortality rates. Much of Napoleon's success relied on his excellent officer staff. However, The combination of smoke and poor communications forced even generals to lead from the front. Naturally, officers riding on horses and dressed in bright uniforms made them

conspicuous targets and subject to unusually high casualty rates. For example, at the Battle of Borodino in Russia, 12 French generals were killed and another 27 wounded.

The Draft. Each year, as his wars dragged on, increasingly younger recruits were called up to replace the soldiers buried on battlefields across Europe. Overall, there were some 3,000,000 conscripts called up to serve in Napoleon's armies. Between 1801 and 1804, 60,000 men were called up each year. In 1805 that number rose to 210,000 as the War of the 3rd Coalition started. By the end of his regime, Napoleon was reduced to calling up 14-year olds. Not old enough to shave, but old enough to die for their emperor, they were known as the Marie Louise Boys after Napoleon's current wife and empress.

As the annual number of conscripts rose, so did the number of deserters and shirkers. Some got married to escape service. Others mutilated themselves, a common tactic throughout history.

Contrary to popular belief, not all of Napoleon's soldiers adored their emperor.

Josephine: Napoleon's one true love?

Josephine Beauharnais was Napoleon's first wife, and possibly the only true love in his life. The daughter of a plantation owner in Martinique whose lands were ruined by a hurricane, she went to France, where she married the aristocrat, Francois, Vicomte de Beauharnais, by whom she had two children, Eugene and Hortense. Unfortunately, Francois was killed during the Terror and Josephine was briefly imprisoned. Being an adept social climber, she became the mistress of several influential political figures, including Barras, one of the leaders of the Directory. In 1795, she met the rising general, Napoleon, became his mistress, and married him although he was six years her junior and she

doesn't seem to have liked him that much as the picture below seems to suggest.

On the other hand, Napoleon was very much in love with her. During his first Italian campaign he sent her passionate love letters 127 days in a row, writing in one: "I awake full of you. Your image and the memory of last night's intoxicating pleasures has left no rest to my senses." Meanwhile, back at home, Josephine was having an affair with another officer, entertaining him and her friends by reading Napoleon's love letters out loud.

Napoleon did get his revenge. Upon finding out about the affair, he kicked Josephine out of the house. After begging him to take her back and promising to be a good wife, she was allowed back in. Napoleon, however, was hardly the ideal husband, having multiple affairs over the years before divorcing Josephine for a younger woman and dynastic purposes.

Napoleon's Egyptian Fiasco

The Egyptian campaign was a poorly planned affair from the start. Napoleon landed a good distance west of his target, Alexandria. However, he failed to provide adequate supplies for the march, losing a large number of men from dehydration and heat exhaustion before he even fought a battle. This forced the French to plunder the countryside, which led to bad relations with the Egyptians, which in turn confined French control to only part of the Nile Delta. Even Napoleon hinting he might convert to Islam did little or nothing to improve the situation.

Napoleon met the defending Mamelukes at the Battle of the Pyramids (7/21/1798), supposedly telling his men, "Soldiers, forty centuries look down upon you!". As splendid, fierce, and brave

as the Mamelukes may have been, they were no match for the firepower of the French army, which lost only 29 dead and 200 wounded compared to thousands of Mamelukes. As a tribute to their bravery, Napoleon maintained a regiment of Mameluke cavalry after returning to France.

The Battle of the Nile. Two things worked against the French when the British Lord Nelson caught up with Napoleon's fleet. One was the British cannons had flintlocks that would fire immediately instead of fuses that had to be lit. This allowed British gunners to time their firing with the roll of their ships more precisely, giving them better aim. The second problem was Napoleon's neglect to supply the fleet properly, forcing French crews to subsist on half rations. Thus the French crews were weak and sick when the British showed up and couldn't even escape to Corfu, which would have at least saved part of the French navy.

During the Battle of the Nile, the French ship Orient exploded when fires reached its powder magazine. Its 15-ton rudder was hurled 1000 meters away from the ship. Blazing bits of the ship fell all around, setting the British ships, Alexander and Franklin both on fire, although sailors managed to quench the flames. A chunk of mast landed on the Swiftsure that was big enough to be made into a coffin (that was later presented to Nelson).

The entire French squadron was either destroyed or captured in this battle, with only three ships capable of being refitted for British service. In human terms, the British suffered 213 killed and 677 wounded, while the French lost between 2000-5000 killed and wounded. One British seaman reported ' An awful sight it was, the whole bay was covered with dead bodies, mangled, wounded, and scorched, not a bit of clothes on them but their trousers.'

A desperate attempt to get home. Having been cut off from France, Napoleon tried the unlikely scheme of marching through the Ottoman and Hapsburg empires to get home. However, his artillery was captured while crossing a river, and the British helped the Turks repulse him at the old Crusader capital of Acre. Therefore, the French had to retrace their steps back to Egypt, where they were still cut off by the British navy.

In order to stretch his supplies for his own troops on the march back to Egypt, Napoleon had 2,441 Turkish prisoners executed. He tried to get his doctors to execute them by overdosing them with opium, but the doctors refused. Despite paintings showing Napoleon doing such things as bravely visiting soldiers stricken by plague in the pesthouse of Jaffa (below), one of his surgeons sent the French government a formal complaint, charging his commanding officer with criminal neglect of his own wounded.

The Rosetta Stone

Although the French invasion of Egypt proved a costly fiasco, it also triggered an intense fascination in anything Egyptian and led to the discovery of the Rosetta Stone and translation of Egyptian Hieroglyphics.

The Rosetta Stone was a bilingual inscription in Greek and Egyptian from 196 B.C.E. that allowed Francois Champollion to crack the code and decipher Egyptian hieroglyphics. The key clues were cartouches, oval boxes containing Hieroglyphics that corresponded in position to the proper names Ptolemy and Kleopatra in the Greek inscription. Champollion then found other examples of those hieroglyphics in the text and used those and words in the corresponding positions of the Greek text to decipher more

symbols, and so on. It took years to completely decipher the Egyptian text, but this was the start.

Napoleon's Irresponsible Younger Brother

Lucien Bonaparte, Napoleon's younger brother was a flighty, irresponsible spendthrift and woman chaser that Napoleon made Minister of the Interior. It was Lucien who rigged the election in 1800 ratifying the new constitution for the Consulate. While the real tally apparently was 3.5 million against and only 1.5 million in favor, Lucien's math came up with 3,011,007 for and only 1562 opposed. This would serve as the model for counting votes in future elections under Napoleon.

Lucien's administrative ineptitude, corruption, public ostentation, and extra-marital affairs extended well beyond counting votes, providing Napoleon's minister of police, Joseph Fouche, with a very thick file. In fact, when Fouche read a summary of this file to Lucien and Napoleon, the younger Bonaparte resigned.

However, something had to be done with him, so he was sent as ambassador to Spain, where, influenced by a huge bribe, he negotiated a poorly written treaty. When Napoleon rejected this treaty, Lucien fled Spain at night so he could keep the bribe. He then published a pamphlet comparing Napoleon to various dictators. His final break with Napoleon came over an affair he was having while his wife died in childbirth. A resulting illegitimate child and quick civil marriage led to a scandal and his exile to Italy.

French society and fashion after the Terror

Revolutions are more than just political events and France during this era was no exception. During the Terror not even prostitutes dared go out at night, and no one had fun (except maybe kids playing with toy guillotines), unless attending propaganda plays put on by the government is considered fun.

After the Terror all that changed, and, much like Restoration England following Cromwell's rule, France experienced a period of excess in reaction to the previous repression. Paris was once again "Fun City", while public depravity supposedly

reached new heights, as men no longer tipped their hats to ladies, obscene graffiti appeared everywhere, and illegitimate births proliferated along with absurd costumes in Paris and 10-day old (i.e., one revolutionary week) beards in the countryside.

The great tradition of French restaurants was one legacy of the Revolution, as private chefs of the now defunct nobility opened cafes to cater to the new rising middle class with money.

Theatre was very popular, especially after the repression of Jacobin rule. Tickets were cheap, so that citizens of all classes might go one or two times a week. Under the Napoleonic dictatorship with its censorship of newspapers, the enthusiasm normally given to politics was channeled into devotion to popular actors.

When a particularly popular actor came onstage his devotees went wild while devotees of another actor were visibly annoyed.

The only thing more popular than attending the theatre seemed to be fighting to get in.

Also popular in the aftermath of the Terror was a craze for dancing. It seemed that everyone loved to dance, dance, dance, and wherever a large enough space was available, dance halls were opened: gardens, palaces of former aristocrats, and unused convents. Paris had hundreds of dance halls, and even the church of St. Sulpice on the Left Bank was painted yellow and had a wooden dance floor erected over the gravestones of its cemetery.

Adding to the frenzy in 1797 was the introduction of a scandalous new dance, the Waltz, which one person described as "a dance of familiarity demanding the amalgamation of two dancers." Making it more scandalous yet were the scanty fashions of the day.

And fashion was where one saw real revolutionary changes. One fashion for women whose relations had been guillotined during the Terror was to wear crossed belts on their backs or thin red ribbons around their necks.

Another way to commemorate friends or relatives guillotined in the terror was to adopt the haircut of the condemned to clear the neck of any hair that might interfere with the guillotine blade. Either all the hair was cut short and choppy, as was quickly done to the condemned before execution, or cut in the "dog's ears" style with long shocks of hair left to fall down the sides of the face while the hair on the back of the neck was cut to the hairline.

Along with these fashion statements came a new type of event: the victims' ball. Only those with a document attesting that its bearer had a spouse or close relative who had been killed in the terror were admitted. Such soirees were so popular that some people even forged documents for admission. Instead of bowing to their partners, men (and some women), would jerk their heads in imitation of the moment when the guillotine came down on one's neck.

Fashions changed at a dizzying pace so that fashion journals (which were already published every five days) couldn't keep up. Leading socialites, such as Madame Recamier (portrayed below by David) and Josephine Beauharnais, called the shots in women's fashions in much the same way movie stars do today.

The dominant fashion of the age was the Neo-classical look, supposedly based on the dresses worn by women of ancient Greece and Rome. Neo-classical gowns, often of the flimsiest materials, clung to the wearers' bodies, revealing their charms in unheard of ways.

At the extreme edges of fashion were young members of the nouveaux riches, the women known as the Merveilleuses ("marvelous ones"), while their male counterparts were referred to as Incroyables ("incredible ones"). They especially enjoyed flouting older social conventions, often for the shock value, by sporting outrageous and exaggerated looks.

The Incroyables liked to mimic the look of untidy old age with spectacles, unkempt hair, baggy trousers and absurdly high collars. Some of them, known as the Muscadin for their heavy musk cologne, roamed the streets in gangs carrying bludgeons and canes with which to attack Jacobins.

The more extreme Merveilleuses would adorn their hair with giant bows and headgear that looked like oversized baseball caps. And even this was too conservative for some who bared even their breasts or wore gowns of transparent materials, despite the warnings of doctors about

the health hazards, since France's climate was not like that of Greece. Their only concession might be to wear a shawl.

A new social order. Despite the Revolution's egalitarian ideals, no one could change the fact that some people are sharper and more ambitious than others. Therefore, after the Thermidorean Reaction, a new social order emerged in France. Many of the new aristocrats belonged to a newly rich (*nouveaux riches*) middle class that had made their fortunes during the Revolution or even off of it: government contractors for the army, smugglers getting such valuable commodities as sugar through British blockade, and speculators buying cheap assignats and abundant Church lands to sell later for profit.

When the Catholic religion had been under attack by the Jacobins, some astute businessmen cornered the market on Bibles and religious books, selling them for outrageous profits when religion was reestablished.

These new aristocrats mimicked the older nobles' tastes to excess, exhibiting exorbitant waste and extravagance on clothes, jewels, and furniture. Some hostesses, one of whom was called Madame Free and Easy, even changed their furniture to match the gowns they were wearing that night.

But the real nobility under Napoleon was the military, and France was permeated with a martial spirit from top to bottom.

- Schoolboys went to classes in uniforms.
- Operas were presided over by dragoons with drawn swords.
- Furniture was decorated with eagles and other military insignia.

France virtually worshipped its defenders, who often took undue advantage of this, elbowing civilians aside and monopolizing the ladies. Any civilians failing to make way might be beaten up. Soldiers even dueled openly in the streets endangering innocent by-standers.

Napoleon even created a new imperial nobility from his officers. His brothers became princes, while his ministers became grand imperial dignitaries: Grand Elector, Grand Chancellor, Grand Marshal of the Palace, Grand Admiral, etc. In 1808 he created new counts, dukes and barons, endowing them with revenue producing property. Although this was an aristocracy of merit, most titles were hereditary.

Women's (lack of) Rights under Napoleon
Whatever aspirations and apparent gains women may have seemed to gain during the Enlightenment and Revolution were quickly dashed by Napoleon. The following quotations pretty much sum up the emperor's attitude toward women.

- "A bride must be made to realize that on leaving the tutelage of her family she passes under that of her husband."
- "Women should stick to knitting."
- "The husband must possess the absolute power and right to say to his wife: 'Madam, you shall not go out. You shall not go to the theater, you shall not receive such and such a person; for the children you will bear shall be mine.'"

Besides his own personal opinions about the place of women, Napoleon may also have seen lowering their status compared to men as a way of helping men reconcile themselves to his exalted status over them by giving them someone to look down on. As a result, wives had no rights in administration of common property. They were forbidden to give, sell or mortgage property and could acquire property only with their husbands' written consent.

"A Tearless Eye"

It was Napoleon's minister of police, Joseph Fouché, who really kept France under lock and key. After murdering nobles and fellow clergy

for the Jacobins, who recalled him because his methods were too violent even for them, he murdered Jacobins for the Directory as their minister of police.

Therefore, it wasn't too hard for Fouché to make the transition to working for Napoleon when he overthrew the Directory. It didn't seem to bother Napoleon either. According to Talleyrand, Napoleon's foreign minister, Fouché was a man "with a heart as hard as a diamond, a stomach of iron, and a tearless eye".

Among those on Fouché's payroll were Napoleon's personal secretary, his wife, Josephine, and the personal chef of Louis XVIII (in exile in Britain). Fouché sometimes knew even more about Napoleon's personal life than he did. For example, he once shocked Napoleon with the knowledge that he was having an affair with an opera singer, Maria Grassini. What even Napoleon didn't know, but Fouché did, was she was having another affair behind Napoleon's back with a violin player. As Talleyrand put it, Fouché minded his own business, and everyone else's too.

Fouché did miss one attempted assassination on his boss in 1800. Luckily, Napoleon's carriage driver was drunk and inadvertently swerved away from the bomb as it exploded. After a good dressing down from Napoleon, Fouché went to work to find the culprits. He traced the horseshoe of one of the exploded horses to its blacksmith, and from there tracked down the would-be assassins.

However, no one had anything on Fouché, who neither drank, nor smoked, or chased other women. His wife shared his values and insensitivity to others' suffering. Ironically, he was a doting husband and father who let his kids run wild at home.

Napoleon Becomes Emperor

Jacques-Louis David's portrayal of Napoleon's coronation as emperor

Having fought his enemies to a standstill and made France the most feared and respected power in Europe, Napoleon could now pursue his next goal: becoming emperor of France. This was a tricky situation, since the French people might not take kindly to getting a new king so soon after getting rid of the old one. Using the title of emperor rather than king would partly ease people's misgivings and also give them a sense of France's imperial superiority over the rest of Europe. Napoleon approached the title in stages, first getting himself elected consul for ten years and then for life.

Realizing the move to emperor was a bit trickier, Napoleon decided he had to make the French people realize how much they loved him. So he engineered a fake assassination plot against himself. To that end, French double agents got British funds to support French assassins in a murder plot that was miraculously "discovered" just before it was sprung! As the French people were recovering from the shock of almost losing their savior and hero, Napoleon sent them to the polls to elect him emperor.

In the "election" he won by another resounding "landslide".

The day after his coronation, the emperor gave bronze eagles to his regiments as standards reminiscent of the Roman Empire. He even created a new nobility of dukes and counts from his officers in order to make a court that rivaled the splendor of other European courts.

Invading Britain

Napoleon planned to invade Britain in 1805 using a fleet of over 2000 gunboats without keels, which were cheaper to build, but unable to withstand the harsh conditions of the English Channel. The ideas of digging a tunnel under the channel or transporting an army by hot air balloon were so far-fetched that even Napoleon didn't consider them. Napoleon's invasion fleet cost France and its subject states a ton of money, largely due to corruption, officials claiming they had 2343 boats, when there were only 1730, of which only 672 were actually seaworthy.

Naval Warfare in the Age of Napoleon

Although the essential nature of naval warfare (i.e., sailing ships delivering broadsides of cannon fire against one another) had remained largely unchanged since 1600, incremental improvements had taken place. Frame-first construction based on blueprints was now used, producing faster and more streamlined hulls. Sails and rigging had become progressively more sophisticated, and artillery was increasingly more powerful and deadly.

The Spanish ship, *Santissima Trinidad* (above), was probably the finest warship of its day. This was largely because Spain's empire gave it access to mahogany, which was stronger than the oak other nations used for their ships. A first rate ship such as the *Santissima Trinidad* might require as many as 5,000 trees to build, with each tree yielding 800 board feet. It weighed 1400 tons and had a two-foot thick hull that stood as high as a five-story building. It also had four gun decks, and 144 guns, 30 of which could hurl a 32-pound cannon ball through a three-foot thick hull at a range of 1.5 miles.

Terms of service. In the British fleet, discipline and living conditions were harsh, while pay and

provisioning were irregular. Large crews were necessary just because most work had to be done by hand. Stores, ammo, provisions and cannons had to be loaded on ships by hand. There were dozens of sails to furl and unfurl, pumps to keep bilge water at a safe level, and extra pumps during battle to put out fires and wash blood off the decks. Since the powder magazine was located in the middle of the ship removed as far as possible from enemy fire (and fire in general), much of the crew was involved in running individual charges from there up to the gun decks.

As a result of these labor needs (900 people on Lord Nelson's flagship, the HMS *Victory*), many sailors were pressed into service from foreign ships, which was a leading cause of the War of 1812) and an undeclared war between France and the U.S. (1798-1800). Adding to France's problems was the fact that many of its best naval personnel had left during the Revolution. Nelson's flagship alone had 70 foreigners, one of them French. Despite regulations, a number of women also served: running powder, tending the wounded, and several even helping "man" the guns at Trafalgar. Along those lines, there would be several "ships' boys" aboard some of whom were on career tracks and advancing to junior officer positions at a very young age.

Communications. Without radios and the ability to move quickly between ships to transmit orders, communication and coordination was limited to signaling by code with semaphore flags. Below is Lord Nelson's final message to his fleet before the battle of Trafalgar.

Tactics. The French and Spanish, still thinking of ships as fighting platforms, packed them with marines, which often created confusion and fights between soldiers and sailors. Along those lines, they usually fired at masts and rigging to slow enemy ships for boarding. The British, in contrast, fired at hulls to sink enemy ships and kill their personnel. British crews were also trained to lie down until ready to fire. The British used flintlocks on their cannons more due to the heavier rolling of their ships.

Breaking the line at Trafalgar. For over two centuries, the standard way of fighting naval battles had been to line up two fleets parallel to one another and slug it out with broadsides. Poor communications and the inability to closely coordinate movement of ships prevented much variation from this pattern.

However, at Trafalgar, the British admiral Nelson had his ships sail between the French and Spanish ships. This had several advantages. First, his ships advancing perpendicular to the enemy line of fire presented smaller targets for them to hit at more oblique angles. Secondly as each ship passed between the prow of one ship and stern (back) of another, it could fire cannons from both sides of the ship against a largely undefended part of the enemy ships. Finally, an entire line of British ships doing this at point blank range, one after the other, would totally devastate the respective sterns and prows of the enemy ships.

The new British tactic of breaking the line proved decisive at Trafalgar, with the French and Spanish losing 19 ships and the British losing none. After this, Britain had undisputed mastery of the seas. However, victory came at a heavy cost for the British, as its great admiral, Lord Nelson was killed by a sniper firing from the ratlines of an enemy ship. Therefore, news of this great victory was met with very mixed emotions in Britain. One of the major centers in London is still named Trafalgar Square in honor of this battle.

The Face of Battle at Sea.

Fighting on the gun deck of a warship was probably as close to Hell on earth as one could get back then. As opposing fleets approached, sailors withdrew their guns into the ships for firing. To maximize their effect, cannonballs were heated red hot and had to be loaded with hand tools. The guns, which got extremely hot

after several shots, also to be manhandled back into position.

The combined effects of a broadside were devastating, even for those firing the cannons. Since the gun decks were only 6' high, the tremendous crash of the guns firing often led to permanent deafness, while the acrid smoke from the black powder quickly filled the confined space.

For those on the receiving end, things were much worse. A single volley of 32-calibre cannon could obliterate a hull and clear a deck of its gunners, tear cannons loose, and send 100's of deadly splinters flying through deck, each one a lethal weapon in its own right. Guns blasted loose from their moorings would roll over and crush sailors blinded by the smoke. Floors made slippery with blood and filled with frightfully cut up bodies further complicated any efforts to continue, while the screams of the wounded were added to the already deafening roar of cannons.

The middle orlop deck was the safest place on ship, but also the most ghastly, since that was where the surgeons operated. Typically it was painted white to reflect what little light there was, but the floor was red to hide the river of blood flowing from the surgeon's table. On the ceiling of a Spanish ship there was a crucifix, the last thing many sailors ever saw. The horrible nature of the wounds often left the ship's surgeon with little to do except amputate limbs or turn the patients over to a priest for last rights. The low ceilings forced surgeons to work on their knees at makeshift tables.

War of the Third Coalition

Icebreakers. During the Battle of Austerlitz, as Russian and Austrian troops were retreating over an ice-covered marsh Napoleon had his artillery fire to break the ice and drown the fleeing soldiers.

Taking his lumps.

No one got beaten up more by Napoleon than Francis I of Austria (1792-1835). Having lost two wars in Italy to the Little Corporal, he lost big time again at Austerlitz and had to surrender lands containing another 3,000,000 of his subjects. Before it was all over, he would lose another war and more land to Napoleon, then get dragged in on the wrong side of the invasion of Russia in 1812. In addition Napoleon declared the Holy Roman Empire defunct. However, seeing something like this coming, Francis had created a separate imperial crown for the Hapsburgs, so the Hapsburg Empire could limp along for another century.

“The only man in Prussia.”

The indecisive Frederick-William III of Prussia refrained from joining Austria and Russia against France until after Napoleon had defeated them at Austerlitz and formed the Confederation of the Rhine, which also infringed on some Prussian territories. Not until then did Frederick-William decide to join the war. However as quickly as Prussia entered the war, its forces were shattered by Napoleon's blitzkrieg (1806). This sparked Napoleon's caustic remark calling Frederick-William's wife, Louise of Mecklenburg, who showed much sterner resolve than her husband during this crisis, the only man in Prussia.

“What a massacre! And for no outcome.”

While Napoleon claimed a glorious victory at Eylau with only 7600 casualties, it was at best a bloody draw. More likely there were 25,000 French killed & wounded as opposed to 15,000 Russians. Marshal Augereau's corps alone, when caught in the flank by the devastating fire of 70 Russian cannons, lost over 12,000 of its 14,000 men in a matter of minutes.

After Eylau, French soldiers no longer spontaneously yelled out “Vive l'empereur” As one French commander put it: “What a massacre! And for no outcome.”

To replenish his ranks for a new campaign in 1807, Napoleon called up not just the class of 1807, but also 80,000 boys from the class of 1808, a disturbing trend that would continue.

[Back to flowchart](#)

NAPOLEON'S YEARS OF TRIUMPH AND FALL (1805-1815)

"Great empires die of indigestion."—Napoleon

The rest of Europe saw Napoleon's imperial crown as part of a plan to rule all of Europe. This triggered the war of the Third Coalition of Austria, Britain, and Russia against France and Spain (1803-1807). Once again, Napoleon was faced with his old nemesis, Britain, that "nation of shopkeepers" (to quote Adam Smith) whose navy shielded them from his military might. If only the British navy could be removed, Napoleon could slip across the Channel with his army and bring Britain to its knees. His plan for removing the British fleet was to lure it to the West Indies with the combined French and Spanish fleets. This would leave the Channel open for the French to cross. However, the British commander, Nelson, guessed this plan and managed to blockade the French and Spanish fleets in the Spanish port of Cadiz. When they tried to break out, the British crushed them in the Battle of Trafalgar (1805). Britain remained safe as its navy still ruled the waves.

Seeing his failure at sea, Napoleon marched his army eastward where he met the much larger combined armies of Austria and Russia at Austerlitz. Concentrating his forces in the center, he drove through and split the Russian and Austrian armies, winning possibly the most brilliant victory of his career (1805).

Austerlitz gave Napoleon the power to declare the Holy Roman Empire defunct, making him the heir apparent of Rome's imperial grandeur. He also used this opportunity to form the Confederation of the Rhine from the German princes grateful to him for the lands he had given them before. The Confederation consisted of about half of Germany and formed a large buffer zone on France's eastern border. This upset Prussia who had been sitting on the sidelines, but now decided to join the war. However as quickly as Prussia entered the war, its forces were shattered by Napoleon's blitzkrieg (1806).

Finally, there was Russia. After a bloody indecisive battle in the snow at Eylau, Napoleon won a decisive victory at Friedland. Now he could impose

his kind of peace on Europe. Negotiations between Napoleon and Czar Alexander I were conducted on a raft in the middle of the Nieman River while Frederick William III of Prussia had to await his fate along the shore. The settlement for Prussia was not kind, taking nearly half of its land and population to help carve out the Grand Duchy of Warsaw, a revived Poland that owed its existence and lasting loyalty to Napoleon. France and Russia recognized each other's spheres of influence, but France certainly emerged as the dominant power in Europe. Besides France, Napoleon directly ruled Belgium, Holland, the West Bank of the Rhine, the Papal States, and Venice. Then there were the states that were nominally free but lived under French law, administration, and usually French rulers who happened to be Napoleon's relatives: the kingdom of Naples, the Kingdom of Italy, Switzerland, the Confederation of the Rhine, the Grand Duchy of Warsaw, and Spain (after 1808). Finally, there were Napoleon's allies who had to follow him in war: Austria, Prussia, and Russia. Only Hitler ever came this close to ruling all of Europe.

The Continental System and Spanish Ulcer. One power Napoleon could not reach was Britain, whose navy safely sheltered it against any continental invasion. The ill-fated invasion of Egypt and the Battle of Trafalgar both bore this out. But Napoleon was determined to bring Britain to its knees, and this time decided to strike the "nation of shopkeepers" where it would hurt the worst: the wallet. With most of Europe under his control, Napoleon imposed the Continental System to stop all European trade with Britain. Hopefully, this would strangle Britain economically and force it to come to terms. And while it did hurt Britain, it also hurt the rest of Europe wanting to trade for Britain's cheaper industrial goods. By a combination of bribing officials, forging documents to mask the British identity of merchant ships, and outright smuggling, the Continental System leaked like a sieve. Even Napoleon secretly bought British goods.

One big leak in the system was Portugal, which refused to join the embargo against Britain. Napoleon decided to plug this leak by taking over Portugal, which he did in several months. However, in order to reach Portugal, French troops had to cross Spain. Therefore, Napoleon decided to

replace the Bourbon dynasty ruling Spain with a French regime led by his brother, Joseph, figuring the Spanish people would prefer French rule to that of the corrupt monarchy. However, Napoleon had completely misread the spirit of Spain.

On May 2, 1808, a popular revolt in Madrid and the severe French repression following it triggered a general uprising that spread like wildfire across Spain. What Napoleon had figured to be a simple operation turned into a full-scale war that dragged on for five years. The Spanish revolt was the first example of another country's nationalism being turned against France, although it was led largely by priests and nobles who stood for the conservative values of the old regime.

The Spanish method of fighting was ill suited to Napoleon's style of warfare. Instead of meeting the French in large pitched battles on Napoleon's terms, the Spanish launched hit and run raids to cut enemy communications and supply lines and ambush stragglers and foragers. Such warfare (called *guerilla*, meaning "little war") tied down some 360,000 French troops in Spain and Portugal. The desperate fighting for the town of Saragossa alone cost the French 60,000 casualties. Even a simple messenger going to France required an escort of several hundred cavalry. This war came to be called the "Spanish Ulcer" since it slowly bled the life out of the French army. Napoleon himself said the invasion of Spain was the worst mistake of his career.

Making matters worse for the French was British help led by Sir Arthur Wellesley (the future Duke of Wellington) and Sir John Moore. Wellesley in particular was a capable commander who knew how to use the stark Spanish landscape against the French, tying them down to long supply lines that were vulnerable to guerilla raids. Bit by bit, the French forces were worn down and driven back. In 1813 the last French army in Spain was defeated and driven out, leaving behind Joseph's silver chamber pot as a victory trophy to commemorate the "Spanish Ulcer".

Another shock came to Napoleon in 1809 when Austria, apparently inspired by the Spanish revolt, declared war on France again. Napoleon won the war quickly, but not before Austrian forces, showing their own nationalist spirit, inflicted a

sharp defeat on the French. In the ensuing peace, Austria lost still more land and population as the price of daring to fight France. Napoleon also claimed an Austrian princess, Marie Louise, as his bride, hoping she would provide him with a legitimate heir to his throne as well as give him ties to established royalty.

This short war against Austria should have indicated to Napoleon that the tide of revolution was starting to favor France's enemies. Both Austria and Prussia were adopting French innovations such as drafting subjects into their armies, while Prussia went so far as to abolish serfdom. Speeches by such men as Johannes Fichte urged the unification of a strong Germany against France and showed a strong undercurrent of nationalism developing there. However, it was events further east that would be Napoleon's real undoing.

Napoleon's invasion of Russia. There were several reasons for Napoleon's decision to invade Russia in 1812. Czar Alexander I felt snubbed by Napoleon's marriage to an Austrian princess (even though Napoleon had first asked the Czar for a Russian princess and been snubbed). Mutual jealousy between the two rulers, and Russian resentment of Napoleon's revival of Poland (as the Grand Duchy of Warsaw) and the Continental System, which was costing it valuable trade with Britain, also contributed to war.

Whatever the reasons, Napoleon was determined to crush Russia. However, instead of relying on the typical Napoleonic blitzkrieg, he decided to use the weight of numbers, some 600,000 men drawn from all over his empire, to crush his foe. In June 1812, the Grand Army of France entered Russia.

While most people hearing of Napoleon's Russian campaign think of the horrible Russian winter and march out of Russia, the march going in was rough too, with summer heat, flies, and dust plaguing the French and their allies all along. The Russian scorched earth policy of burning anything of use to the French before they could get it also wore them

out. Garrison duty, desertions, and even suicides from despair over the endless march reduced the French army to 125,000 men by September when the Russian General Kutuzov was finally forced to make a stand at the village of Borodino some 70 miles west of Moscow. What ensued was the fiercest, bloodiest, and most horrible day of fighting in the Napoleonic era, and possibly in history up till then. Once again Napoleon discovered that nationalist fervor was not something that could be confined to the French people. After a full day of hammering mercilessly at each other, 40,000 Russians and 20,000 French were lost, including 39 French Generals who were killed or seriously wounded. Even though the Russians eventually retreated, with those sorts of losses, nobody could really claim a victory.

The Russians left Moscow to the French, but little else in the way of food and other supplies. Soon after its occupation, Moscow mysteriously went up in flames, thus denying the French any shelter as well. Napoleon, hoping the Czar would come to terms, waited until October 19 to leave Moscow and head home. By then it was too late. The Russian winter was quickly setting in.

By Russian standards it was not such a bad winter. But for an army that had brought mosquito nets for continuing its campaign into India, it was a disaster. Men froze from exposure to the elements and starved as supply lines broke down and the surrounding scorched earth yielded little or no food. Many of the French horses died simply because Napoleon had refused to let them be shod for ice. With each day, the situation became more desperate and the retreat degenerated into a rout. At the Berezina River, total chaos ruled as the mob of French soldiers crowded frantically onto two bridges to escape oncoming Russian forces. One of the bridges broke under the weight of the crowd and thousands drowned or were crushed in the ensuing panic. An island that formed over the pile of bodies still stands as a grim reminder of the French disaster in Russia. Of 600,000 men who invaded Russia, only 55,000 made it back. Napoleon's message to the French people upon returning to France was: "His majesty's health has never been better."

The end of the Napoleonic Empire. Napoleon's defeat in Russia was a signal to the rest of Europe to rise up against French rule, and Austria, Prussia,

Russia, and Britain formed a new coalition to liberate the continent. Napoleon still had some fight left in him and raised new armies to defend his empire. However, the emperor was not as sharp as he used to be and he wasted men on needless marches and countermarches. The year 1813 saw heavy fighting as the allies pushed the French back across Germany. The decisive battle came at Leipzig in the "Battle of the Nations" where 300,000 allies and 190,000 French desperately fought for three days. When France's Saxon allies turned on them in mid battle, the French were forced to retreat through Leipzig. Unfortunately, the one bridge providing an avenue of escape was prematurely blown up, and thousands of French soldiers either surrendered or were drowned. The remaining French forces quickly retreated across Germany while the rest of Napoleon's empire in Holland, Italy, and Spain threw off the yoke of French rule. In fifteen months of disastrous campaigning, Napoleon had lost one million men.

Yet he refused to accept a settlement that would leave him with France. Maybe he hoped for an upsurge of nationalist fervor such as had happened during the crisis of the Revolution in 1793. In this he was sadly disappointed, because France was worn out by nearly a quarter century of warfare. The ranks were now filled with the "Marie Louise Boys", called that since they were too young to shave, but not too young to die for their emperor. While Napoleon showed flashes of his old brilliance in hurling one invading army after another back from French soil, it was still too little too late. On April 13, 1814, Napoleon was forced to abdicate. The man who just recently had ruled most of Europe now had to leave France in disguise to save himself from mobs of French people bitter over having suffered so much from his wars.

However, Napoleon was not quite through. The allies had generously given him the tiny Mediterranean island of Elba to rule, even with an army of 900 men. In 1815 he escaped to France, seized power, and fought one last battle against the Anglo-Dutch and Prussian armies near the Belgian village of Waterloo. It was a poorly run battle on Napoleon's part and ended in total defeat for the French. This time Napoleon was exiled to the island of St. Helena off the southern tip of Africa. He died there in 1821. . His legend has continued to grow to the present day.

The Spanish Ulcer

Francisco Goya's painting of the outbreak of the Spanish revolt on May 2, 1808

The Spanish revolt was the first example of another country's nationalism being turned against France, although it was largely led by priests and nobles who stood for the conservative values of the old regime.

“Godless” is how many people in Europe viewed Napoleon and the French. After all, one of the primary targets of the Revolution had been the Church. Therefore, it was to be expected that the fight against Napoleon became a virtual crusade to save the Church.

And “holy wars” tend to be among the most vicious.

The Spanish method of fighting (called guerilla, meaning "little war") was ill suited to Napoleon's style of warfare. Instead of meeting the French head-on, they launched hit and run raids to cut enemy supply lines and communications while ambushing stragglers and foragers.

Spanish guerillas wore no uniforms and often included women and children, making it hard to tell friend from foe. This made French soldiers extremely nervous and prone to lash out in retaliation against any citizens. Of course, many of their victims would be innocent bystanders, triggering more Spanish attacks, more retaliation, and so on. Each time this cycled around, the rage and resentment on each side would grow, making this a very frustrating, mean and bitter war.

In a series of 85 etchings known as The Disasters of War, Francisco Goya depicted war as no artist

before him ever had. Goya pulled no punches, showing its stark brutality, idiocy and meaninglessness. Even today, the graphic realism of these etchings shocks us out of our complacency about the true nature of war. Goya didn't even back off from the subject of rape by French soldiers or the savagery that women themselves could exhibit in retaliation.

The countryside was especially hard for to control since, any stragglers and foragers were subject to attacks by roving bands of guerrillas, some only armed with knives. Supply trains had to be protected by large forces of French troops. Even getting a message to France required an escort of several 100 men. Eventually, Napoleon had 360,000 soldiers committed to Spain.

And even that wouldn't be enough.

Saragossa. One of the major struggles the Spanish campaign was the struggle for Saragossa, which was defended by 32,000 regulars and 50,000 men, women and children.

Every house was loop-holed.

Every street was barricaded and peppered with mines.

Avenues of fire were cleared and artillery placed behind barricades to sweep the streets.

What happened here seemed to anticipate the horrors of urban warfare over a century later during World War II in such cities as Stalingrad, Warsaw, and Berlin. A French soldier caught in this fighting probably described it best:

"When we broke into a house we had first to inspect it thoroughly from bottom to rooftop. We learned from experience that a sudden interrupted resistance could be a warlike ruse. Often as we were installing ourselves on one floor, we would be shot at point-blank range

from the next floor up through openings made beforehand in the ceiling. The nooks and hiding places we frequently found in these old-fashioned buildings facilitated such murderous ambushes.

Above all we had to keep a watch on the rooftops. With their serge shoes, the Aragonese would circulate as easily and with as little noise as cats and were therefore able to return to make unexpected forays well behind the front line of operations. It was a veritable war of aerial fighters."

"If the enemy disputed the entry to a room, we would pierce loopholes facing his own and there would be shooting from both sides. As the room separating the combatants quickly filled with smoke, this enabled a sapper to crawl forward on his stomach and make his way under the enemy's musket barrels. The sapper would then stand up, beat with all his might on the musket barrels with an iron bar and force the Spaniards to pull their muskets back. Our grenadiers would then move forward, throw grenades, fill in the loopholes and force the enemy to seek refuge in another, more distant room, where a new battle would begin."

Saragossa was besieged 4 times and cost France 60,000 men. Street fighting in the second siege took approximately a week. Of Saragossa's 82,000 people, 54,000 died before the city fell.

The war in Spain came to be called the "Spanish Ulcer" since it slowly bled the life out of the French army. Napoleon himself said the invasion of Spain was the worst mistake of his career.

Even priests took part in the fighting to stop the "godless" French.

The Spanish did have help, especially from Britain whose navy could keep it supplied. However, the British force of 40,000 regulars was no match for Napoleon. However, the situation changed when war with Austria forced Napoleon to leave Spain.

The British general, Sir John Moore, seized this opportunity and suddenly turned on the French, defeating them in the mountains and snow near Corunna. Although the British won the battle, Moore was killed. His replacement, John Wellesley, better known to history as the Duke of Wellington, would carry on the struggle.

As much as anything, the somewhat dry and barren terrain of Spain and Portugal proved a decisive factor in the Peninsular War. Wellesley's strategy was to build a vast system of earthworks at Torres Vedras along Portugal's west coast and force the French to besiege him there.

While their navy could easily supply the British, the larger French army had to rely on long supply lines to survive. Such supply lines were especially vulnerable to the hit-and-run tactics of the Spanish guerrillas, forcing the French to commit large numbers of troops to protect them.

Nowhere did the term "Spanish Ulcer" apply better than here, as the French strength slowly bled away.

The final defeat of the French forces took place at Vittoria in 1813. Among the spoils of battle, the British took Joseph Bonaparte's silver chamber pot. The following year, the French were finally expelled from Spain.

The Wounded

"I have 300,000 men to spend."--Napoleon

General Kleber who served with Napoleon in Europe called him “the general who consumes 6000 lives a day”. Despite constant pleas from his doctors, Napoleon never created a permanent army medical corps.

On the eve of Austerlitz, the chief surgeon didn't even have a single bandage.

In the Russian campaign wounded soldiers had to be bandaged with tree bark.

Sometimes dirty cannon swabs were used for bandages, often infecting patients with tetanus.

One group of sixty doctors arriving at a field hospital and seeing its appalling conditions immediately went home.

In 1809, Napoleon finally authorized the first permanent field service with ten companies of army nurses (1250 men) and a few ambulances. But it was too little too late. After the Battle of Essling, surgeons had to put the wounded in lean-tos of river reeds covered with coats taken from dead soldiers. They were fed butchered cavalry horses cooked in helmets hammered into pots.

The wounded would be put next to patients with infectious diseases, thus complicating their chances of recovery. The lucky ones would be put on a layer of straw. More often they were just laid in the mud. One wounded officer was put on a pile of straw-covered dung. Many casualties were adolescents whose bodies weren't developed enough to withstand the shock of being wounded along with exposure to infectious diseases.

Orderlies with 3 weeks training had to carry out hundreds of amputations with passing surgeons just marking with a piece of chalk where to cut. Most of those patients died agonizing deaths. All accounts mentioned the horrible stench of a battle's aftermath.

Huge flies soon covered soldiers not rescued from the battlefield, filling their wounds with maggots that ate them away inch by inch.

The victims were unable to do anything except watch and go mad. The bodies of the dead left unburied in the summer heat would swell with gases until they burst. Many soldiers' accounts mention the sound of these bodies exploding after a battle.

Russia

"A single blow delivered at the heart of the Russian Empire, at Moscow the Great, at Moscow the Holy, will instantly put this whole blind apathetic mass at my mercy." --Napoleon

While most people associate Napoleon's Russian campaign with the horrible Russian winter and march out of Russia, the march going in was rough too, with summer heat, flies, and dust plaguing the French and their allies all along. The Russian scorched earth policy of burning anything of use to the French before they could get it also wore them out. Even fresh drinking water was a rare and valuable commodity.

Hardly traveling lightly. One French colonel brought books, maps, a carriage, two wagons, twelve horses, and six servants. Some officers, believing they were going on to Persia and India, even took mosquito nets instead of winter clothing.

As one French soldier described the march:

"Of all the unpleasant things we had to endure one of the most unbearable was the thick dust which enveloped us on the march, much of the way in very dry weather. I recall that at one stage, so as to prevent anyone taking a wrong turning, a drummer was stationed at the head of each battalion and his job was to beat the drum all the time. This fact alone will indicate just how dense the clouds of dust were."

"Not a soul in sight, not an inhabitant in the villages we passed through. One would have said

that even the animals wanted to escape notice." — French soldier

Even fresh drinking water was a rare and valuable commodity.

"These exceptional marches added to the great shortages we had to put up with, thinned our ranks to an unexpected degree, and thousands of men disappeared within a very short time. Hundreds killed themselves, feeling no longer able to endure such hardship. Every day one heard isolated shots ring out in the woods near the road. Patrols were sent to investigate, and they always came back and reported a cuirassier, an hussar, an infantryman, a Frenchman, or an ally had just committed suicide."-- French veteran

"We passed through the smoking ruins [of Smolensk] in military formation with our martial music and customary pomp; triumphant over this desolation, but with no other witness to our glory than ourselves."

On September 7, The Russians finally made a stand at Borodino in probably the most terrible battle of the Napoleonic wars.

"...on every side one saw nothing but the dead and dying. When I rode over to congratulate one young officer, Monsieur de Gramont, on his good bearing, I witnessed some terrible things. He told me that he had nothing to complain of and that all he wanted was a glass of water. He had barely finished speaking when a cannonball cut him in two. I turned to another officer and said how sorry I was about poor de Gramont. Before he could reply his horse was struck dead by a cannonball. And a hundred other incidents of this kind. I gave my horse to a cuirassier to hold for half a minute and the man was killed. I was covered with earth thrown up by shells."--French Captain at Borodino

"When a Russian soldier has been killed, you still have to push him to make him fall down." — Napoleon

"Those Russians let themselves be killed like machines...They are citadels that have to be demolished with cannon"-- Napoleon.

The carnage was so great that soldiers piled the bodies of the fallen into protective walls. After a full day of mercilessly hammering at each other, 40,000 Russians and 20,000 French were lost, including 39 French Generals who were killed or seriously wounded. Even though the Russians eventually retreated, with those sorts of losses, nobody could really claim a victory.

That night an icy rain added to the misery of the wounded and the number of dead.

On September 14, 1812 the French entered Moscow, only to find it completely abandoned. As they marched through empty streets they were *"filled with wonder at the sight of such complete solitude, they responded to the awe inspiring silence of this modern Thebes by a silence equally solemn....These warriors shivered inwardly at the lonely echo of their horses hooves among the deserted palaces."*

Although there was enough shelter left, it was often used in ways that further angered the Russian people. Most notably, the French used Uspensky Cathedral to stable their horses, something the Russians saw as a sacrilege.

Soon after its occupation, Moscow mysteriously went up in flames, most likely on orders from the Russian governor to deny the French food and shelter. The fire destroyed as much as two-thirds of Moscow.

Looting after the burning of Moscow just made the situation even worse for the French.

"Enormous fires had been lit in the middle of the fields, in thick cold mud and were being fed with mahogany furniture and gilded windows and doors. Around these fires, on litters of damp straw, ill protected by a few boards, soldiers and officers, mud stained and smoke-blackened, were seated in splendid armchairs or lying on silk sofas. At their feet were heaped or spread out cashmere shawls, the rarest of Siberian furs, cloth of gold from Persia and silver dishes in which they were eating coarse black bread baked in the ashes and half-cooked, bloody horseflesh."

The Retreat. On November 9, the French reached the ruins of Smolensk finding few supplies left there. Army regulations dictated that supplies could only be given to military units, not individuals. Therefore, thousands of soldiers that had lost contact with their units were denied what little food that existed.

"When they [the garrison in Smolensk] saw in Napoleon's wake a mob of tattered ghosts draped in women's cloaks, odd pieces of carpet, or greatcoats burned full of holes, their feet wrapped in all sorts of rags, they were struck with consternation. They stared in horror as those skeletons of soldiers went by, their gaunt, gray faces covered with disfiguring beards, without weapons, homeless, marching out of step, with lowered heads, eyes on the ground, in absolute silence, like a gang of convicts."—French soldier

During the crossing of the Berezina River, a Russian shell hit one of the bridges, triggering a panic in the French army. Soldiers in front were pushed into the gap in the bridge and into the freezing river, with others being pushed on top of them. Eventually a mound of bodies formed that let others cross to the far side. Eventually,

an island formed over those bodies and remains there to this day.

The bravest of the brave. Only Marshall Ney, musket in hand, led a heroic rear guard action against overwhelming Russian forces while the rest of the French army had disintegrated into headlong flight. Ney, called the bravest of the brave, was the only French leader whose reputation was enhanced by the Russian disaster. After disappearing with 7,000 men, he re-merged a week later with only 1,000 survivors.

The retreating French and their allies were also attacked by peasants avenging the destruction of their lands and churches by the "godless French"

At night, soldiers would fall asleep by campfires that would melt the surrounding snow. After the fires went out, the water would refreeze, leaving only frozen corpses by morning.

Some soldiers would burn houses just to get warm, while others, crazed by the cold, reportedly threw themselves into the flames.

Only 50,000 out of 600,000 men, made it home. Napoleon sent this message to reassure the French: *"The emperor's health has never been better."*

A Ground-level View of Waterloo

Napoleon's final battle at Waterloo, while maybe his most famous fight, was hardly a masterpiece of strategy. The emperor wasted much of the day with fruitless cavalry attacks against the British infantry squares, interspersed with artillery bombardments that caused frightful casualties. While it was the cavalry charges that captured the artists' and public's imagination, it was the artillery that did the real damage.

As one British veteran recalled: *"We had 3 companies almost shot to pieces, one shot killed and wounded 25 of the 4th company, another of the same kind killed poor Fisher, my captain, and 18 of our company...and another took the 8th and killed or wounded 23...At the same time poor Fisher was hit as I was speaking to him, and I got all over his brains, his head was blown to atoms."*

British troops considered the French cavalry charges a relief, since they were ineffective against solid infantry squares and forced the French artillery to stop their much more deadly work. One officer referred to these "repeated visits from [the] Cuirassiers. I do not say attacks, because these cavalry columns on no occasion attempted to penetrate our square, limiting their approach to within 10 or 15 yards of the front face, when they would wheel about, receiving such fire as we could bring to bear upon them, and, as they retired, en passant, that from neighboring squares.

Concerning the attacks by the French cavalry, one British officer referred to these "repeated visits from [the] Cuirassiers. I do not say attacks, because these cavalry columns on no occasion attempted to penetrate our square, limiting their approach to within 10 or 15 yards of the front face, when they would wheel about, receiving such fire as we could bring to bear upon them, and, as they retired, en passant, that from neighboring squares."

"...the horses of the 1st rank of cuirassiers, in spite of all the efforts of their riders, came to a standstill, shaking and covered with foam, at about 20 yards distance...and generally resisted all attempts to force them to charge the line of serried steel."

"No actual clash was made upon us. Now & then an individual more daring than the rest would ride up to the bayonets, wave his sword about & bully; but the mass held aloof, pulling up within 5 or 6 yards; as if, though afraid to go on, they were ashamed to retire. Our men soon discovered they had the best of it, & ever after would, when they heard the sound of cavalry approaching, appear to consider the circumstances a pleasant change (from being cannonaded)!"

The Murder of Napoleon?

Although the official autopsy report said Napoleon died of stomach cancer, like his father, there has been a popular theory that he was murdered, more specifically, gradually poisoned with arsenic mixed with his wallpaper paste. Since arsenic stays in the body, it built up to toxic levels by inhaling minute amounts of it over time until it killed Napoleon. The evidence supporting this is arsenic found in his hair follicles. (Several locks of his hair were saved and have occasionally come up for auction.)

Another, less diabolical theory concerns Scheele's Green, a coloring pigment used in fabrics and wallpapers since the 1770s. If it gets damp and moldy, the copper arsenite in the pigment transforms into a vapor form of arsenic that can cause Gosio's disease, a malady that did kill a number of people exposed to this pigment in the 1800s. A piece of his wallpaper has survived, and analysis shows it did have arsenic in it. However, it's believed that the amount of arsenic was too small to kill him. Rather, it may have just exacerbated the stomach cancer that doctors originally said killed Napoleon.

107. PRUSSIAN REFORMS IN THE NAPOLEONIC ERA AND THEIR IMPACT

Prussia provides possibly the best example of how Napoleon's success inspired other countries to copy many of his reforms in order to break free of French rule. Napoleon was especially severe with Prussia joining his enemies in 1806, taking nearly half of its lands while exacting an indemnity equal to 140% of its annual government revenue **before** it had lost those lands. In addition its army was limited to 42,000 men. This humiliating settlement brought home to Prussia's rulers the need to copy the reforms that had obviously given France so much dynamic power and vitality during the revolutionary period. These reforms came in two ways: those imposed by the government from above in order to prevent the need for revolution from below, and those suggested by intellectuals, notably Johannes Fichte, in regard to education.

There were three main parts to the reforms imposed by the government. The most sweeping of these was the Edict of Emancipation in 1807, which ended serfdom, feudal privileges, and all class distinctions. Even Jews were given full civil rights by this document, a rarity in Europe at that time. Along with this came a land reform in 1811 that gave the peasants two-thirds of the land they had worked for the nobles while leaving those nobles the other third of land in compensation for their loss. Finally, there were major military reforms, such as promotion by merit and banning foreign recruits, which hopefully would instill some of the same high morale and efficiency into the Prussian army that had made the French army so effective in recent years.

Later in the century, Otto von Bismarck would unify Germany under Prussian rule and institute similar social reforms in order to remove any need for revolution. In each case, there were few political reforms giving the German people any real power in their government. However, these two waves of reforms in the 1800's would make Germans more willing to accept without question the policies of a government they saw as benevolent and ruling in their interests. This would influence many ideas on the modern welfare state, but also, along with the educational reforms discussed below, make the German people prone to fall victim of political groups posing as their benefactors while

just using this facade to get power for their own purposes.

The major figure in Prussia's educational reforms was Johannes Fichte. In his "Addresses to the German Nation", he tackled two issues: creating a German national spirit and instilling it into the German people. First of all, Fichte blamed Prussia's and the German people's recent humiliations on a lack of national spirit, which gave rise to moral failure and complacency. From the English philosopher, Edmund Burke, he borrowed the idea that the nation is the only enduring thing on earth, and thus the living expression of divine immortality. However, while France and England had strong national traditions and institutions to bind them together, the German people had virtually none and thus must find or create them. For Fichte, the best candidates for such German traditions were the Germanic tribes that had conquered the Roman Empire. It was here that one would find the simple and noble virtues that had made those people great and would make Germans great once again. He also saw the Holy Roman Empire, the so-called First Reich, as a unifying institution that Germans could look back to for inspiration.

As far as instilling these traditions in the German people, Fichte saw the public schools as the place where this could be done. While Prussian schools had been and remained places for technical education, this new agenda of instilling nationalist spirit into its children also became an essential element in public education for many modern nations in addition to Prussia and later Germany.

Just as the government's social reforms made the German people somewhat complacent about their rulers, these nationalist ideas had a similar effect on Germany's intellectuals. Fichte's educational proposals would translate intellectual ideas into action on a national scale and give the intellectual community a major role in implementing these reforms. However, it also made the intellectuals a part of and subordinate to a system that valued action over contemplation. This put pressure on them to affirm government policies with absolute conviction rather than questioning them in the spirit of skepticism needed to keep an intellectual climate fresh and vibrant. Therefore, the intellectuals, along with the German people in general, were prone to falling under the sway of people who would use

their power for less than benevolent purposes. The most notable example of this was the rise of Hitler and the Nazis, which led to World War II. Ironically, Fichte, who proposed many of the reforms that would eventually lead to this disaster, was himself an idealistic liberal, the sort of person that Hitler would work so hard to eradicate.

108. REVOLUTION AND REACTION IN EUROPE (1815-1848)

"After me, the Revolution- or, rather, the ideas which formed it- will resume their course. It will be like a book from which the marker is removed, and one starts to read again at the page where one left off."--Napoleon

The Congress of Vienna. Despite his defeat, Napoleon had several important effects on Europe. For one thing, he had spread the idea of liberalism, especially in Western and Central Europe. By the same token, he had also spread the idea of nationalism in East and Central Europe. Finally, his defeat prompted the victors to meet at the Congress of Vienna with the goal of turning back the clock to restore the Europe that had existed before the French Revolution. This was especially the goal of the brilliant Austrian minister, Metternich who led much of the deliberations at Vienna.

The most pressing issue was what to do about France: punish it for causing all this trouble, or restore it to its former position as one of the great powers. Realizing that breaking up France would upset the balance of power, destabilize Europe, and lead to more revolutions, the allies restored it to its old position, punishing it with only a mild indemnity and short military occupation. However, the new king, Louis XVIII, was a constitutional, not an absolute monarch. Even in defeat, the French Revolution had made progress.

There were other changes in the political map of Europe and the world. Britain took South Africa from the Dutch to secure its sea route to India. In compensation, the Dutch got the Austrian Netherlands from Austria, which in turn received control of Northern Italy. The Grand Duchy of Warsaw formed by Napoleon, continued to exist as the Kingdom of Poland, although its king also happened to be the Czar of Russia. And Germany, thanks largely to Napoleon's administrative work, was consolidated into 38 states. These last three changes would all contribute to nationalist revolts in succeeding years.

For the time being, the Congress of Vienna did restore the old order and a period of relative international peace known as the Concert of Europe, since it saw the major powers working largely

together for several years to guard the common peace and old order. However, the ideas born in the French Revolution and spread by Napoleon had not been eliminated. The seeds of revolution had taken root and were spreading rapidly across the face of Europe. Like it or not, the age of kings was in its twilight and a new age of democratic and nationalistic reforms and upheavals was dawning.

The pattern of revolts. The period 1815-48 saw periods of apparent tranquility broken by recurring waves of revolution. In two of three cases (1830 and 1848), these revolutionary movements started in France and inspired similar outbreaks all over Europe. Generally, revolutions in Western Europe focused on liberal reforms, since, with the exception of Belgium, nation states with a strong middle class were already established there. Eastern Europe, with its multi-national empires, saw more nationalist uprisings as various ethnic groups wanted independence from the Hapsburg, Ottoman, and Russian empires. Germany and Italy, in the middle of Europe, were especially turbulent since they were striving for both national unification and liberal civil rights.

A basic pattern of events emerged during this period. Authorities would think they had crushed the ideas of liberalism and nationalism. However, they had merely driven these ideas underground where they would continue to spread and revolutions would flare up again. While most of them would be suppressed, one or two would succeed and might prompt more liberal reforms in countries where the uprisings had been put down. Rulers would again think they had suppressed the revolutionary ideas, and the cycle would repeat. There were three major waves of revolutions: in the 1820's, 1830's, and 1848.

In 1820 the revolutions started in Spain and spread to Greece, South America, and Germany. Most of these were put down, but Greece and the South American colonies did win their independence, with a constitutional monarchy established in Greece and republics in South America. The next wave of revolutions would start in France in 1830 and spread to Poland, Belgium, Italy, and Germany. While the uprisings in Germany, Italy, and Poland were crushed, France won a slightly more liberal constitutional monarchy, Belgium won its freedom,

and more liberal reforms were peacefully passed in Britain.

The final, and biggest, wave of revolutions occurred in 1848, with some fifty uprisings taking place across Europe. The French this time established a republic, only to have it taken over by a dictator, Napoleon III, and turned into the Second Empire. Elsewhere, other revolutions collapsed, but they did lead to some reforms. Serfdom was abolished in the Hapsburg Empire while a weak constitutional monarchy was established in Prussia. Despite apparent failure, nationalist reformers would learn from their mistakes and set more realistic goals and strategies toward attaining national unity in Germany and Italy by 1871.

Revolutions in the 1820's. It took only five years before a new wave of revolutions threatened the old order recently reestablished by Metternich and the Congress of Vienna. Ironically, it was one of the more backward countries of Western Europe, Spain, that led the way. A number of liberal army officers, apparently influenced by the ideas of the French Revolution, rebelled against the corrupt and repressive rule of the Bourbon king, Ferdinand VII. As if on cue, riots and revolts broke out all over: in Italy, Germany, Russia (1825), the Spanish American colonies, and Romania and Greece in the Ottoman Empire. In most cases these revolts were put down. Austria suppressed the revolts in Italy and unrest in Germany. France, despite some protests from Britain, put down the revolution in Spain. The new czar, Nicholas I, had no trouble crushing the Decembrist Revolution led by liberal army officers (many of whom thought that their battle cry, "Constantine and Constitution", referred to their liberal candidate for the throne, Constantine, and his wife. Likewise, the Ottoman Turks put down the Romanian uprising.

However, in two cases on the fringes of European power, Greece and the Spanish American colonies, revolutions succeeded for reasons peculiar to each situation. In the case of the Greek revolt, it was largely a romantic sentiment for ancient Greece, home of democracy and Western Civilization that sparked popular support for the Greeks. The fact that the Greek rebels were descendants of Slavic invaders of the early middle ages, not the Greeks from the time of Pericles and Socrates, made little impact on the European public. In fact, many of

them, including the Romantic poet, Byron, went there as freedom fighters. In the end, the European powers, having little regard for the non-Christian Turks and fearing Russian aggression that might threaten the balance of power in southeastern Europe, pressured the Ottomans to grant Greece its freedom. In the style of the day, the Greeks established a constitutional, not absolute, monarchy in 1832. It was the first major break in the old order since the Congress of Vienna.

The Spanish American colonies had taken advantage of the revolution in Spain to throw off the yoke of Spanish rule. Much of their inspiration came from the newly formed republic to the north, the United States. It was the United States that also stood up to protect the Americas from foreign intervention in the famous Monroe Doctrine in 1823. More important than the fledgling American republic's stand was Britain, which supported the revolutions so it could break Spain's mercantilist monopoly on trade and open new markets for British merchants to exploit. Spain could ignore the Monroe Doctrine, but it could not ignore the power of the British navy, so its American colonies went free.

However, independence brought two sources of instability to Latin America (**covered in FC.108A**). For one thing, most Spanish bureaucrats fled back to Spain, leaving few trained bureaucrats to handle government business. As a result, the armies that won the revolutions were often the only means of keeping matters under control. Second, with Latin American markets now open for free trade, Britain and other European countries encouraged the production of one type of commodity in each nation, such as beef in Argentina or copper in Chile. This made each new nation too dependent on international markets for its one product. Therefore, if the market for their product fell, their economy would have nothing else to fall back upon. This happened to El Salvador in the late 1800's when cheaper industrially produced dyes destroyed the need for its indigo dye, thus wrecking its economy. Together, these factors led to unstable economic and political structures in Latin America encouraging rule by military dictatorships. Misrule and poor economic conditions would lead to more military coups and revolutions, that would further destabilize the economy and the new government, leading to more revolutions and so on.

Revolutionary fever spreads: the 1830's. By the mid 1820's, most of Europe was pacified once again. However, the ideas of nationalism and liberalism, still simmering under the surface, broke loose again in 1830. Once again, the trouble started in France. The government of the restored king, Louis XVIII (1815-24), was a conservative constitutional monarchy with a legislature elected by a narrow electorate of 100,000 property owners. Louis realized that, after a quarter century of revolution, he had to treat the French people with care. His brother and successor, Charles X (1824-30) was not so wise. He censored the press, restored the clergy's position in the schools and politics, tried to bring back feudalism, gave pensions to nobles who had lost lands and rights from the Revolution, and dissolved the legislature.

In 1830, the Parisians revolted and barricaded Paris' narrow streets. The army refused to fire on the crowd, and Charles fled to England (a common habit for deposed kings back then). Now the question was: what type of government to set up. Students, intellectuals, and the Parisians wanted a republic. However, the middle class, probably with the backing of the more conservative peasantry, prevailed in its desire for a constitutional monarchy. The new king, Louis Philippe, known as the "Citizen King", was a man with little to commend him except that he was both a Bourbon and a former revolutionary, thus a compromise candidate who satisfied no one. Admittedly, his constitution was a bit more liberal than the previous one, with 200,000 property owners given the right to elect the legislature. Things did settle down in France for a few years, but not before revolutionary turmoil flared up all over Europe.

Word of events in France triggered revolts in Belgium, Italy, Germany, and Poland, plus giving further impetus to a reform movement in Britain. Austria put down the uprisings in Germany and Italy, while Czar Nicholas I easily crushed the Polish rebellion against Russia. The one successful revolution was in Belgium where religious and linguistic differences with the ruling Dutch caused deep resentment that erupted into open rebellion in 1830. Austria and Prussia wanted to put this revolt down, but France and Britain supported the Belgian cause, largely to keep the other two powers from meddling so close to their shores. Since Austria and

Prussia were also preoccupied with the Polish revolt, France and Britain could pressure Holland to recognize Belgian freedom in 1831. As was becoming the norm, a constitutional monarchy was established.

Although Britain did not experience revolution, it did see a strong reform movement that liberalized the criminal code and culminated in the Reform Bill of 1832. Electoral representation was redistributed to reflect the shift in population to the rapidly industrializing northern counties. The vote was extended to about 20% of British men (twice of what it was before). The Reform Bill of 1832 also opened the door for more liberal reforms as the century progressed: extending the vote to urban workers (1867) and miners (1884) and also instituting the secret ballot. Finally, after a long struggle, even women would get the vote in 1917. Although Britain remained technically a constitutional monarchy, by the early part of this century it was essentially a modern democracy.

The Revolutions of 1848. The success of revolutionary and reform movements in Western Europe and frustration at the failure of other similar movements in Central and Eastern Europe led to the spread of liberal and nationalist ideas in the 1830's and 1840's. Economic forces also played a role in spreading discontent. A series of bad harvests in the 1840's caused starvation (with one million people dying in Ireland from a severe potato famine), which led in turn to higher food prices, bankruptcies, unemployment and urban unrest. Once again, events in France sparked a new wave of revolutions.

The government of the "Citizen King", Louis Philippe, had proven to be conservative, corrupt and unpopular, and in 1848 revolution broke out in Paris. Just like in 1830, the barricades went up in Paris' narrow streets, many soldiers refused to fire on the crowd, and the king fled to Britain. And just like before, revolutionary fever spread all over Europe, with close to 50 revolutions erupting in the German states, Italian states, and Hapsburg Empire.

The suddenness and scale of the uprisings caught rulers completely by surprise. In Germany, they agreed to more liberal constitutions, while a convention was held at Frankfurt to establish a national parliament for all of Germany. In Italy, the

Austrians were driven out of Milan and Venice, while rulers in Naples, Tuscany, and Piedmont agreed to liberal reforms. In the Hapsburg Empire, a Hungarian revolt triggered similar revolts by Czechs, Croats, Galicians, and Transylvanians living under Hapsburg rule. Metternich, the conservative prime minister and architect of the Congress of Vienna, was forced to resign, and the emperor fled to Innsbruck. It seemed like the old regime was about to collapse all over Europe. But just as events in France had set off these revolutions, events there led the way in suppressing them.

This time, the French established a republic where all Frenchmen could vote for delegates to a convention to draw up a new constitution. However, it reflected the more conservative views of French peasants and middle class, which touched off riots by the urban masses suffering from lack of food and shelter in the recent economic troubles. The army met the crowd's cry of "Bread or Lead" with a hail of lead from artillery fire, killing 10,000 demonstrators. This was a turning point in suppressing radicals both in France and across Europe.

In France, the establishment of the Second Republic led to the election of Napoleon Bonaparte's nephew, Napoleon III, who, like his uncle, used a military coup to extend his presidency and then make himself emperor of the Second Empire (1852-70). Victor Hugo, in his *The History of a Crime*, described this coup in grim terms that probably would apply to such events at any time:

"Suddenly, at a given signal, a...shower of bullets poured upon the crowd....Eleven pieces of cannon wrecked the Sallandrouze carpet warehouse. The shot tore completely through twenty-eight houses. The baths of Jouvence were riddled. There was a massacre at Tortoni's [cafe]. A whole quarter of Paris was filled with an immense flying mass, and with a terrible cry...."

"Adde, a bookseller of 17, Boulevard Possonniere, is standing before his door; they kill him. At the same moment, for the field of murder is vast, at a considerable distance from there, at 5, Rue de Lancry, M. Thirion de Montauban, owner of the house, is at his door; they kill him. In the Rue Tiquetonne, a child of seven years, named Boursier,

is passing by; they kill him. Mlle. Soulac, 196, Rue du Temple, opens her window; they kill her...

"New Year's Day was not far off, some shops were full of New Years' gifts. In the Passage du Saumon, a child of thirteen, flying before the platoon firing, hid himself in one of these shops, beneath a heap of toys. He was captured and killed. Those who killed him laughingly widened his wounds with their swords. A woman told me, 'The cries of the poor little fellow could be heard all through the passage.' Four men were shot before the same shop...."

"At the corner of the Rue du Sentier an officer of Spahis, with his sword raised, cried out, '...Fire on the women.' A woman was fleeing, she was with child, she falls, they deliver her by the means of the butt-ends of their muskets. Another, perfectly distracted, was turning the corner of a street. She was carrying a child. Two soldiers aimed at her. One said, 'At the woman!' And he brought down the woman. The child rolled on the pavement. The other soldier said, 'At the child!' And he killed the child...."

"In the Rue Mandar, there was, stated an eyewitness, 'a rosary of corpses,' reaching as far as the Rue Neuve Sainte-Eustache. Before the house of Odier twenty-six corpses, thirty before the Hotel Montmorency. Fifty-two before the Varietes, of whom eleven were women. In the Rue Grange-Bateliere there were three naked corpses. No. 19, Fauborg Montmartre, was full of dead and wounded. A woman, flying and maddened with dishevelled hair and her arms raised aloft, ran along the Rue Poissonniere, crying, 'They kill! they kill! they kill! they kill! they kill! they kill! they kill! they kill!'"

Despite its violent beginning, Napoleon III's rule was much more peaceful than that of his uncle. France's prosperity rapidly grew as he promoted the building of industries and a centralized railroad network. He also put Paris through an extensive urban renewal project, providing the city with wide boulevards that critics were quick to point out could not be barricaded so easily in the event of revolution. Napoleon's reign would come to an end in 1870 after a disastrous war against Prussia in its final stage of unifying Germany. In his wake came the Third Republic of France. With the exception of Nazi rule in the 1940's, democracy has prevailed in France ever since.

Meanwhile, in the rest of Europe, the defeat of the more radical elements in France gave heart to other kings and princes reeling from the current wave of revolutions. Uprisings in Italy, Germany, and the Hapsburg Empire, were crushed as quickly as they had erupted and nearly overthrown established governments. By the end of 1848, the old regimes were back on top, and nothing seemed to have been gained.

Even in failure, the revolutions of 1848 did have positive results. For one thing, several reforms, such as the abolition of serfdom in the Hapsburg Empire and the granting of at least nominal constitutions in the German states signaled some progress. The spirit of reform extended even further east to Russia where serfdom was abolished in 1861. Second, despite their failure, the revolutions spread the popularity of liberal and nationalist causes. Failure also taught reformers to be more realistic in trying to attain more liberal reforms or national unification. Two such men in particular, Camillo Cavour in Italy and Otto von Bismarck in Germany, clearly recognized these lessons and skillfully put them to work in building nations forged, as Bismarck would put it, from "blood and iron".

Nineteenth Century Art to c.1850

Artistic standards in France (and to a large extent, the rest of Europe) had been ruled since the 1600s by the Academies of Painting and Sculpture, Music, and Architecture all founded during Louis XIV's reign. In 1795 these were combined into the Académie des Beaux-Arts, which continued to exercise strong conservative influence on the arts. Painting, in particular was supposed to cover appropriate topics (e.g., history, classical culture, religion, and portraits of important people) and exhibit a polished style.

In the nineteenth century, the Academic style came under increasing criticism as being artificial and limited in subject matter, leading to a split between Neo-Classicism, which continued to follow the Academy's standards, and Romanticism, which forged new paths in technique and subject matter that would influence the Realists and Impressionists later in the century.

Neo-classicism stressed creating precisely painted images from Greek and Roman myth and history to portray the selfless sacrifices of past heroes in order to inspire present day patriots. Jacques Louis David (1748-1835) was especially prominent, doing paintings of such events as the Oath of the Horatii from Roman legend and Death of Socrates from Greek history.

However, as an apologist for the French Revolution and then for Napoleon, he adapted his style to contemporary events such as the Tennis Court Oath and the death of Marat during the Revolution. David's *Leonidas at Thermopylae* (below) was done to encourage the French to fight to the death for their emperor against the ring of enemies closing in from all around. It didn't work, being more than offset by the sight of entire wagon trains full of the wounded straggling through France.

Jean Auguste Dominique Ingres (1780-1867), who studied under David, was another leader of the Neo-Classical movement, as seen in his portrayal of classical subjects such as Oedipus, Romulus, Vergil and Augustus, Thetis and Jupiter. Like David, Ingres was an apologist for Napoleon, even portraying his apotheosis as a god.

Romanticism, which was also seen in the literature and music of the time, stressed our emotional side and idealized nature and everyday themes through the use of broad brushstrokes of color. Critics called the Romantics' work sloppy since the figures were often kind of blurry instead of precisely drawn (e.g., Turner's "Rain, Steam, and Speed"). The Romantics' more down to earth themes also reflected the more democratic spirit sweeping across Europe at the time.

Theodore Gericault (1791-1824) was a founder and leader of the Romantic school of art. Dying at a young age, he is remembered mainly for *The Raft of the Medusa* (1819), which was a reaction to a scandal whereby sailors set some 150 shipwrecked passengers adrift on a raft without food or water. The painting shows the handful of survivors seven days later trying to flag down a rescue ship.

Francisco Goya (1746 –1828) is hard to categorize, since he is considered both as the last of the Old Masters, being the court artist for the Spanish royal family, and the first modern artist in terms of his techniques and oftentimes radical subject matter. But even his portrait *Charles IV of Spain and His Family* suggests a bit of subversive attitude, being described by Théophile Gautier as resembling "the corner baker and his wife after they won the lottery".

On the other hand, Goya's *Executions of the 3rd of May* (1808), not only protests Napoleon's takeover of Spain, but also the Church's insensitivity to the people's suffering. Notice how the Spaniard (in the white shirt) is bathed in light as he assumes a Christ-like pose of crucifixion before the firing squad. In contrast the Church in the background is shrouded in darkness, signifying it offers no hope for the Spanish people.

Goya did a series of some 80 sketches of the Spanish revolt against Napoleon, appropriately named *The Disasters of War*. The graphic portrayal of violence shows a very modern attitude against war to go with the emergence of total war during the French Revolutionary and Napoleonic era, showing even women involved in the violence of war.

Eugene Delacroix, (1798-1863) is probably the best known of the Romantic painters and is best remembered for *Liberty Leading the People* (1830). In the Romantic period, it was popular to portray Liberty or the nation as a woman whom men would be willing to fight and die for.

Another of Delacroix's paintings, *The Massacre at Chios* (1824) especially roused public support in Western Europe for the Greek revolution against the Ottoman Turks

English painters such as John Constable (1776-1837) often idealized the quiet country life in paintings such as *The Hay-Wain* (1821).

J.M.W. Turner (1775-1851) is best known for *Rain, Steam, and Speed, The Great Western Railway*, (1844). Turner supposedly stuck his head out a train car window in a rainstorm to get a better visceral impression for his painting. His

style seems to anticipate that of the impressionists some 20 years later.

Napoleon's campaigns in the East, France's conquest of Algeria in 1830, and the Greek Revolution against the Turks helped spark more interest in the Muslim world, leading to Orientalism, which often focused on Muslim culture's more sensual aspects (e.g., harems) and themes considered inappropriate if portrayed in a European context. Similarly, artists could get away with these paintings since they contrasted supposed Eastern "decadence" with Western "morality".

Orientalism influenced both Romantic and Neo-classical and artists. In addition to Delacroix's paintings publicizing the Greek Revolution in the 1820s, he did several works on even more oriental themes, such as *The Lion Hunt* (1861), which also seems to anticipate the looser flowing brush strokes of the Impressionists. A Neo-classical artist also involved with the Orientalist movement was Jean-Leon Gérôme (1824-1904), as seen in *Unfolding the Holy Flag*.

After the Revolutions of 1848, a new school of art, Realism, emerged which combined Neo-classicism's realistic techniques with Romanticism's contemporary themes. Founded by artists such as Jean Francois Millet, Honore Daumier, and Gustave Courbet, Realism flouted both the dramatic exoticism and emotionalism of

the Romantics and the stiff moralizing and overly polished style of the academics by doing starkly realistic portrayals of such mundane things as a peasant funeral, stone breakers, and even a dead trout, topics that critics considered beneath the dignity of portraying on canvas. Realism helped set up the next big movement in painting: Impressionism. Gustave Courbet's huge painting of a peasant funeral, *The Burial at Ornans* (1849-50), aroused great indignation for its portrayal of such a humble theme on an epic scale. *The Trout* (1872) may symbolizing his own stifling experience in prison for six months.

A prominent and exceedingly independent woman artist of the day was Rosa Bonheur, whose father was a socialist who advocated equal rights for women and let her pursue an artistic career. She especially concentrated on painting animals, even going into slaughterhouses and dissecting animal parts obtained from butcher shops.

She was also notorious for wearing pants (for which she had to get a permit renewed every six months), closely cropping her hair, smoking cigarettes, and riding horses in the straddling, rather than the "safer" and more feminine sidesaddle position. Buffalo Bill Cody even gave her a prize horse during his Wild West Show's tour of Europe. Below: *Plowing in the Nivernais* (1848).

The Congress of Vienna (1814-15)

The Dancing Congress is how people referred to the Congress of Vienna. Indeed it was a lavish affair with the Hapsburg hosts having to provide forty banquet tables and the stabling of 1200 horses for a guest list that included two emperors and empresses, four kings, two heirs to thrones and three princesses. Besides an endless round of balls, banquets, concerts, and hunting parties, there were masquerades and even a medieval tournament.

However, all the socializing at such events has a real purpose: to help the rival diplomats get to know one another as human beings in a relaxed and low-pressure environment. There is no telling how much this helped negotiations the following day—after everyone had recovered from his hangover.

The guiding spirit of the Congress was the reactionary Austrian minister, Prince Clemens Wenzel Lothar Metternich-Winneburg (1773-1859), who stood for restoring the old order that had existed before the French Revolution. During the Congress, he shamelessly gathered information from and about other delegates by plying them with bribes, liquor and prostitutes and going through their garbage. His efforts to thwart any liberal or nationalist causes during the eight-month congress worked, as not a mention was made of unifying the German nation.

Charles Maurice De Talleyrand-Perigord (1754-1838) was foreign minister for France under the Directory and Napoleon until he resigned in 1807. As Napoleon's envoy to Russia he convinced the Tsar that his boss was a threat to Europe and must be stopped. From 1807 to 1812, he worked as a secret agent for Russia while taking bribes from other hostile countries.

As Napoleon's regime was collapsing, he secretly negotiated with the allies to keep his position and restore Louis XVIII. Napoleon described him as a "sh*t in stockings" for the way he would shift loyalty from one regime to the next. When Talleyrand once described Brie as the "king of cheeses", a French writer remarked it was the only king he ever stayed loyal to. However, his restless intellect was always in overdrive, analyzing and over-analyzing every little move or nuance. When the Turkish ambassador dropped dead after a night of partying, Talleyrand supposedly asked: "What did he mean by that?"

Getting France back in the game. France's fate largely hinged on a stalemate pitting British and Austrian opposition against Russian claims on Poland and Prussian claims on Saxony. Talleyrand agreed to back Britain and Austria if they would support France getting a voice at the Congress. Even though Russia and Prussia got their ways in this dispute, France did get more of a voice in the settlement.

France's penalty was relatively light, all things considered: pay an indemnity of 700,000,000 francs and agree to a five-year occupation by 150,000 foreign troops, who left after only three years.

Liberalism and Nationalism Move East: Greece and Russia

The Greek revolt against the Ottoman Turks sparked both a neo-classical and romantic sentiment in Europe for ancient Greece, home of democracy and Western Civilization. The fact that the Greek rebels were descendants of Slavic invaders of the early middle ages, not the Greeks from the time of Pericles and Socrates, made little impact on the European public. In

fact, many of them went there as freedom fighters. The Romantic poet, Lord Byron volunteered for the Greek cause and died there, although of sickness, not in battle.

By the same token, paintings such as Eugene Delacroix's *The Massacre at Chios* (above) helped stir up much anti-Turkish and Pro-Greek sentiment in Europe during the Greek Revolution.

In the end, it was fear of Russian expansion into the Balkans, more than any romanticized sympathy for the imagined descendants of Pericles, which aroused the French and British governments to declare war on Turkey. The destruction of the Turkish fleet by the French and Russian fleets at Navarino in 1827 helped convince Turkey to give Greece its freedom and deprive Russia of any excuses for further expansion into the Balkans.

In the style of the day, the Greeks established a constitutional, not absolute, monarchy in 1832. It was the first major break in the old order since the Congress of Vienna. Since various Greek factions couldn't agree on a Greek candidate and the French and British wouldn't accept a Russian candidate, a compromise candidate, Otto of Bavaria, was chosen. Unfortunately, the Greeks didn't like Otto either and eventually killed him.

The Decembrist Revolution in Russia (1825). Even in Russia the revolutionary fever was alive, especially among young educated military officers who had been exposed to and inspired by the liberal ideas of the French Revolution. When the supposedly liberal Tsar, Alexander I died in 1825, his brother Constantine who was next in line for the crown, refused it. This left the throne to the conservative and reactionary Nicholas I,

Rumors that Constantine had met with foul play triggered an uprising led by some officers in December 1825. The crowd picked up the battle cry "Constantine and Constitution", many thinking Constitution was Constantine's wife. The new czar, Nicholas I, acted quickly and decisively, having no trouble crushing the

Decembrist Revolution in St. Petersburg before it could gain any momentum.

The Forged Testament of Peter the Great
A major idea driving Western attitudes toward Russia has been a perception of it having a long-term agenda for world domination. While Russia's foreign policy has been no more angelic than anyone else's, much of the West's fear has been based on a forged document, *The Testament of Peter the Great*, which Napoleon fabricated as propaganda to support his war against Russia in 1812. In it Peter plots out Russian expansion, first to take over Sweden and Poland, then dominate the Baltic and Black Seas, then the Middle East, and then ally with either France or Austria to destroy the other.

Finally, "*Russia must then watch for and seize the favourable moment and pour her already-assembled hosts into Germany, while two immense fleets, laden with Asiatic hordes and conveyed by the armed squadrons of the Euxine and the Baltic, set sail simultaneously from the Sea of Azov and the harbour of Archangel. Sweeping along the Mediterranean and the Atlantic, they will over-run France on the one side while Germany is overpowered on the other. When these countries are fully conquered, the rest of Europe must fall easily and without struggle under our yoke. Thus Europe can and must be subjugated.*"

It is hard to estimate how much this fake document has affected the West's policies since Napoleon, although references to it abound in 19th century writings and are even found in the correspondence of President Truman at the start of the Cold War. The allusion to using "Asiatic hordes" to overrun Europe has proven especially frightening to the West and helped drive its actions and attitudes toward Russia ever since.

Post Revolutionary and Napoleonic Fashions

Women's fashions changed radically during the French Revolution, reflecting the whirlwind of political fashions then. The "male style" of cut, prominent in the early 1790s reflected the conservative style associated with constitutional monarchy in Britain.

Napoleonic and post-Napoleonic fashions for women were especially feminine, reflecting the Neoclassical and Romantic cultural movements of the time, as well as a reaction against the assertive role women had played during the revolution. The corset made a big comeback at this time, being joined by the bustle to restrict women's freedom of movement even more.

Another hallmark of ladies' fashions in the 1800s was the bonnet, which, in truly neo-classical spirit, was originally modeled after ancient Greek helmets. However, as the century progressed, bonnets evolved into much more terrifying creatures that, by the early 1900s, intimidated men in fashionable countries into giving women the vote.

Growing differences in men's and women's status also showed in men's fashions which used duller colors & fewer frills, such as lace and ruffles, the main exception being the necktie. The less aristocratic and lethal sword was also replaced by the more practical and less deadly umbrella or cane, making impromptu duels just as easy to start, but much harder to finish.

In the early 1800s, the top hat replaced beaver pelt hats, causing a drastic drop in the price of American beaver pelts on which trappers in the Rockies had made their livings. As Kit Carson said, "The road to hell is paved with top hats."

For beavers, top hats seemed to have paved the road to paradise.

The top hat's initial appearance on the streets of London by its inventor was anything but auspicious. Women fainted, children ran away screaming in terror thinking they'd seen a monster, and the inventor was promptly arrested for disturbing the peace.

Keeping your Louis's straight

Louis XVIII was Louis XVI's younger brother, which, besides raising serious questions about their parents' lack of creativity in naming their children, also begs the question of who was Louis XVII and where was he.

He was the son of Louis XVI who remained in prison after his father's execution in January 1793. He was put in the charge of one Simon the Cobbler who apparently beat the poor boy to death. Although he never was crowned or ruled France, royalists chose to give him a number (XVII) to maintain the fiction of the dynasty's continuity.

The Barbary Pirates and Algeria

One thing that Charles X did accomplish was the conquest of Algeria in 1830. Piracy along the coast of North Africa had been a problem for centuries. From the 1500s to 1800s, the Barbary Pirates may have enslaved as many as 1 million people. When the United States rebelled against Britain, it lost the protection of the British Fleet. After paying ransoms of up to 40% of the federal budget to release American prisoners, the U.S. founded its navy and went after the pirates in two wars (1801-5, and 1816) to clear the way for its shipping in the Mediterranean.

One of the most famous events in those wars was the burning of the U.S.S. Philadelphia, which the pirates had captured in 1803 and used as a gunboat guarding the harbor of Tripoli. One night a party of Americans led by Stephen Decatur stormed aboard the ship and burned it to deny its use to the pirates. Lord Nelson called it the boldest act he had ever seen.

In 1830, Charles X decided to conquer Algeria. While piracy was the main issue driving France to conquer Algeria, the triggering event was supposedly when the Algerian ruler hit a French diplomat in the head with a fly swatter. Algeria would remain a French colony until 1962 when it finally won its independence after a long and bitter rebellion and civil war.

Thanks to slower population growth caused by the abolition of primogeniture, relatively few French emigrated from France during the 19th century, and many of those went to Algeria instead of the Americas.

Punch and Judy

Punch and Judy was a popular puppet show that involved a lot of violence, typically starting with Mr. Punch being abusive to his wife, Judy, and then escalating from there as other characters like the Constable, the Crocodile, and the Ghost. Much of the violence popular then (such as hitting the baby with a stick, dropping it, or letting it go through a sausage machine) today is considered too politically incorrect to portray.

Freedom of the Press

“Freedom of the Press” was a growing factor in liberal politics in the 1800s. This was especially true thanks to the invention of the steam powered printing press which could print 1400 pages per hour, allowing for much broader distribution of newspapers (usually one page broadsheets)

This picture of a cobbler reading his newspaper is indicative of the rising political consciousness newspapers brought and the growing influence of newspaper editors.

The multiplication of newspapers led to a rising political consciousness and the growing influence

of newspaper editors in the absence of actual political parties. When faced with censorship, one way of protesting was to publish blank spots where a censored article would have gone.

To the Barricades: Revolution in the 1800s

As typically happened with revolutions, the triggering event in 1830 was a crop shortage resulting in widespread hunger and unemployment (1827-9). In lieu of public relief for the poor, rich people would give out free doles of wine, not always with the best results, as seen in this picture of such a handout in 1822. While providing people with much-needed calories, getting large crowds of hungry and angry people drunk doesn't always have the best results.

Usually the first response to the cry of revolution was to barricade the narrow city streets with overturned carriages, cobblestones and anything else at hand. In addition to barricades, people on upper stories along the street might throw washtubs, furniture, roof tiles, and anything else that could presumably harm the king's troops.

Also leveling the playing field was the fact that many insurgents had their own muskets with which to meet the king's troops, as in *The Insurgent Grocer* by Honore Daumier (below). Revolutions could also be family affairs, with women and even children taking part.

Favoring the king's troops was their better training and expertise with weapons, tighter discipline, and artillery with which to blast away the barricades.

Oftentimes, the decisive factor in an uprising is the level of loyalty displayed by the government's troops. In 2011, the refusal of the Egyptian army to back the government allowed the insurgency to triumph. Similarly, the defection of 1500 royalist troops with their weapons helped decide the day in the July Revolution of 1830. However, this still proved to be anything but bloodless, as 1800 Parisians were killed and 4500 more were wounded.

The Peterloo Massacre

The so-called "Peterloo massacre" in St. Peter's Field in Manchester (1819) was where the Duke of Wellington crushed a demonstration of textile workers protesting postwar unemployment & high food prices caused by the Corn Laws (tariffs on cheap foreign grain).

British cavalry charging into a crowd of 60,000-80,000 people killed fifteen and injured 400-700 more. It was called Peterloo as a reference to Wellington's victory at Waterloo in 1815. The demonstration was an early indication of the disruptive effects of modern wars on nations' economies as they make the transition from a wartime back to a peacetime economy.

The End of Slavery in the British Empire

Above right: a medallion created as part of Wilberforce's anti-slavery campaign.

Another sign of the times was the abolition of slavery throughout the British Empire thanks to the tireless efforts of William Wilberforce (above) from 1787 to 1833. After getting the slave trade abolished with the Slave Trade Act of 1807, Wilberforce turned his efforts to ending slavery itself throughout the empire. He died only three days after achieving his lifelong goal.

The Irish Potato Famine (1845–1849)

When the Potato was imported from the New World, it seemed ideally suited to the needs of the Irish confined to the poorer 1/3 of Ireland's fields, the other 2/3 being owned and operated by rich English landlords. It was fairly nutritious, grew well in Ireland's cool and wet climate, and stored fairly well. Unfortunately, it was also highly susceptible to the fungus *phytophthora infestans*, which started wiping out potato crops in Ireland and Northern Europe in 1845.

In the German states, where the potato blight also hit, governments provided relief to keep their peasants from starving.

The Irish weren't so lucky.

Although there was enough food grown in the English landlords' fields to feed Ireland's people, it was exported for profit to the markets of British industrial cities. Sometimes it was literally hauled past starving Irish peasants along the roadside, their mouths stained green from eating grass.

The British also refused to send any aid to the Irish, claiming such aid would make them lazy and dependent on British welfare.

Some Irish were so desperate for food that they deliberately let themselves be caught, committing crimes knowing that prisoners in the jails were fed at least something.

In 1847, British Prime Minister, Robert Peel, finally got Parliament to send some relief. Irish laborers were employed building roads. However, owners of toll roads objected to the construction of competing roads, so the Irish built roads that basically went from nowhere to

nowhere. In addition, the backbreaking labor proved deadly to many workers, already weakened by hunger and disease.

Around one million Irish died from starvation, disease, and forced emigration caused by callous landlords evicting them when they couldn't pay their rent. Another two million left Ireland looking for new homes, in most cases America. Because of overcrowding, unsafe conditions, and disease, especially typhus, many more perished from the Atlantic crossing, their vessels being dubbed the "coffin ships".

Lamponing the Citizen King

Almost from the start, Louis Philippe's reign was faced with protest and rebellion. One of the earliest uprisings against him was by the silk workers of Lyon (1832). Being one of the oldest trades in France, the silk workers were also among the best organized, politically aware, and radical of the various labor groups.

Political cartoonists had a field day with Louis Philippe. One cartoon showed the evolution of his heavily jowled face into a *poire*, the French word meaning both pear and dolt or idiot. Another showed him as being two-faced, wearing a mask with a benign expression while his truly evil face lay hidden behind.

More serious artwork criticizing the king also circulated, such as Honore Daumier's *Massacre in the Rue Transnonain* (1834), showing a father and child lying dead in their home after being gunned down by the king's troops. Such works helped galvanize public opinion against the king early in his reign and pave the way for the February Revolution in 1848.

The February Revolution and "Springtime of the Peoples"

As usual, the revolutions started in Paris. When Louis Philippe outlawed banquets where participants would protest his policies, the Parisians skipped dinner and went straight to raising barricades. In the resulting riots, fifty people were killed and revolution erupted. And, as was the custom, the king fled to Britain.

News of the revolution in Paris spread like wildfire, triggering some fifty similar uprisings across Europe such as Berlin, Vienna, Rome, Naples, Venice, and Genoa. The suddenness and scale of these revolts caught rulers completely by surprise. Metternich and the Hapsburg emperor fled, German princes agreed to more liberal constitutions, and a convention was held at Frankfurt to establish a national parliament for all of Germany. However, these uprisings were far from bloodless. For example, in Berlin 230 people were killed defending the barricades in March 1848.

Because of the revolutions' sudden success people referred to this as the "Springtime of the Peoples" to describe the initial euphoric feeling that typically accompanies the opening stages of a revolution before things get serious and nasty. Catholics hugged Protestants and Christians embraced Jews, at least for the time being.

Different people also had different ideas about what the revolutions stood for. Peasants used revolutionary slogans to occupy forests owned by local nobles. Others used revolution to attack landlords, Jews, Protestants, Catholics, soldiers, taxmen, or anyone else they had a grudge against. In fact, it was the fragmented nature of the revolutions that would prove their undoing.

“Bread or Lead”: the Collapse of the 1848 Revolutions

The answer to “Bread or lead”

After overthrowing Louis Philippe, the French established a new government, the Second Republic, where all men could vote. However, this is where things started going wrong, since the new constitution reflected the more conservative views of middle class and peasants, who had no interest in paying extra taxes to help the urban masses suffering from lack of food and shelter in the recent economic troubles.

This touched off riots in French cities where the army, led by General Cavaignac, met the crowds' cry of "Bread or Lead" with a hail of lead from artillery fire, killing 10,000 demonstrators.

This was the turning point in suppressing radicals both in France and across Europe, as the defeat of the more radical elements in France gave heart to other kings and princes reeling from the current wave of revolutions. Uprisings in Italy, Germany, and the Hapsburg Empire, were crushed as quickly as they had erupted.

In Germany, liberals met at Frankfurt in hopes of unifying Germany under a liberal constitutional monarchy. In their excessive optimism they offered the crown to Frederick William IV of Prussia. Unfortunately, he refused to accept a “crown from a gutter” offered to him by a bunch of starry-eyed liberals, thus dashing their hopes for an easy and peaceful unification. In the Hapsburg Empire, 190,000 Russian troops helped crush the Hungarian revolt near Pest (7/20/1849) to keep the revolutions from spreading into the Tsar's territories. This also freed Austrian forces to quell disturbances in Venice and other parts of Northern Italy.

Despite the self-serving nature of Russia's aid, it felt Austria should repay the favor by joining it against Britain and France in the Crimean War four years later. Austria's neutrality in that war would be a source of future trouble between it and Russia that would last all the way to World War I.

In Italy, Pope Pius IX, who had a reputation of being very liberal, even granting amnesty to political prisoners, was seen as the natural leader for a unified Italy. However, Pius backed away from leading (Italian) Catholic subjects to kill (Austrian) Catholics.

He was also disillusioned with liberal causes when many of the political prisoners to whom he had given amnesty joined the revolutions. The assassination of his Minister of the Interior, Pellegrino Rossi, didn't help either. Of course, when he dropped out, Italian nationalists felt betrayed, as reflected in cartoons portraying him as a two-faced traitor.

After Pius IX abandoned the Italian revolutionaries, nationalists led by Mazzini & Garibaldi drove the pope from the Vatican and declared the Republic of Rome. They were eventually driven out by French troops sent by Louis Napoleon.

The Strange Ascent of Napoleon III

The elections in France brought to the fore, Bonaparte's nephew, Louis Napoleon (aka Napoleon III) who was once described as a “man of mystery without a secret.”

He had already tried on two occasions to use the magic of his name to overthrow the French government. The first time he announced to soldiers in Strasbourg that they should follow

him in his attempt to seize power, but they arrested him instead. In 1840 he tried a second time, landing with 40 men and an eagle (actually it was a vulture) to seize power. He was arrested that time too.

Luckily for him, French jails must not have been too secure, because he escaped again to Britain, only to reappear in France for the 1848 elections. Thanks to some timely help, the charisma of his name, and the rumor that if elected he would pay everyone's taxes from his own pocket, he was elected president of the Second Republic.

The constitution of the Second Republic allowed a president only one term of four years. After campaigning for its repeal, Louis Napoleon pulled off a military coup on December 2, 1851, the 46th anniversary of his uncle's great victory at Austerlitz and the 47th anniversary of his being crowned emperor.

Victor Hugo, a source hostile to Louis Napoleon, described the scene in the streets during this coup: "*Suddenly, at a given signal, a...shower of bullets poured upon the crowd....Eleven pieces of cannon wrecked the Sallandrouze carpet warehouse. The shot tore completely through twenty-eight houses. The baths of Jouvence were riddled. There was a massacre at Tortoni's [cafe]. A whole quarter of Paris was filled with an immense flying mass, and with a terrible cry....*

"Adde, a bookseller of 17, Boulevard Possonniere, is standing before his door; they kill him. At the same moment, for the field of murder is vast, at a considerable distance from there, at 5, Rue de Lancry, M. Thirion de Montauban, owner of the house, is at his door; they kill him. In the Rue Tiquetonne, a child of seven years, named Boursier, is passing by; they kill him. Mlle. Soulac, 196, Rue du Temple, opens her window; they kill her...

"New Year's Day was not far off, some shops were full of New Years' gifts. In the Passage du Saumon, a child of thirteen, flying before the platoon-firing, hid himself in one of these shops, beneath a heap of toys. He was captured and killed. Those who killed him laughingly

widened his wounds with their swords. A woman told me, 'The cries of the poor little fellow could be heard all through the passage.' Four men were shot before the same shop....

"At the corner of the Rue du Sentier an officer of Spahis, with his sword raised, cried out, '...Fire on the women.' A woman was fleeing, she was with child, she falls, they deliver her by the means of the butt-ends of their muskets. Another, perfectly distracted, was turning the corner of a street. She was carrying a child. Two soldiers aimed at her. One said, 'At the woman!' And he brought down the woman. The child rolled on the pavement. The other soldier said, 'At the child!' and he killed the child...."

Exactly one year later, Louis Napoleon declared the Second Empire with himself as emperor Napoleon III. (This was in deference to Bonaparte's son, Napoleon II, who died in prison and never ruled, although he had briefly been declared Napoleon II as child.) Louis Napoleon had the odd distinction of being both the first president and last monarch of France.

109. THE AGRICULTURAL BACKGROUND TO THE INDUSTRIAL REVOLUTION

The View From Space

I joke with my students that whatever unit we're studying is the most important unit in history. When we get to the industrial revolution, I tell them I'm not joking so much. After all, nothing has transformed our lives so profoundly in so many ways as the industrial revolution.

One way to look at it is to imagine we are aliens from outer space who have been taking snapshots of earth every hundred years for the last million years or so. We wouldn't see things change that dramatically from one century to the next: a tiny bit of continental drift, the creeping expansion and contraction of some forests and glaciers, but not much else... until the nineteenth century.

For example, consider the first map showing railroads in Europe up to 1820. As the map clearly shows, there weren't any.

The second map shows the growth of railroads by 1940. In that short period of 120 years, railroads have virtually exploded across the map, transforming not only the map, but the lives of the people represented on it and their perceptions of the world. Maps or charts showing the changes in other things, such as urban growth, would tell a similar story on the transformative effects of the industrial revolution.

Introduction. No other event or series of events in history has had nearly the impact of the Industrial Revolution. Most likely, people living in the 1700's could more easily relate to the lifestyle of ancestors 2000 years earlier than to our lifestyle a mere 200 years later. Our life expectancies are more than double that of our ancestors. We travel thousands of miles much more easily, quickly, and comfortably than they could travel 20 or 30 miles. We are in much closer touch with events on the other side of the globe than they were with events in the next village. And the price we pay for our medical care, balanced diet, rapid transportation, and mass communication involves much less effort than what they spent for their more primitive comforts and necessities.

Although industrialization happened rapidly, one can see a long steady build-up toward it in Western Europe over many centuries. The extensive use of water wheels, windmills, and other labor saving devices all put the European mentality in touch with exploiting natural forces and laws to increase productivity. The invention of the clock changed Europeans' attitudes toward time, disciplining and regulating their lives to a degree of precision necessary for industrialization. And the Enlightenment's scientific discoveries laid the foundations for the dramatic industrial and scientific advances of the 1800's. All of these developments took place in Western Europe because of a complex variety of forces that fed back on one another to intensify their effects.

A new agricultural revolution. Just as various forces combined to make Western Europe the birthplace of the Industrial Revolution, several factors combined to focus on Great Britain as the specific area of Europe where industrialization would first take root. One of these was a rapid growth in agricultural production and the labor force that started with the agricultural revolution in the Middle Ages. This led to three lines of development that would later converge to create a new agricultural revolution in the 1700's.

First of all, the three-field system developed in the Middle Ages required nearly all the farmland for growing grain crops. This left little land for grazing cattle, which, in turn, produced little manure for fertilizer. As a result, crop yields were down, forcing peasants to use most of the land for grain

crops, and so on. This made the agriculture fairly stagnant and created the need for a better way of feeding Britain's population.

Another medieval innovation, the heavy plow, also generated a vicious cycle. Since peasants were typically too poor to own enough oxen to pull a plow, they had to share plow teams. As a result, they broke their fields into strips in order to ensure that everyone got at least some of his land plowed. This left everyone's lands interlocked in scattered strips of farmland. Because of that, there was little incentive or opportunity to try new agricultural techniques, since all the peasants had to agree on any changes and switch all of the village's lands to the new system. Getting everyone to agree to any such changes was extremely difficult. As with the three field system, this also made agriculture fairly stagnant, keeping individual peasants too poor to farm independently, forcing them to continue sharing plow teams, and so on. This also created the need for better agricultural techniques.

However, another result of the medieval agricultural revolution, the rise of towns in the High Middle Ages, unleashed forces that pushed for change in two ways. First of all, by the early modern era, the rising middle class had bought up much of the farmland in their ambitions for secure investments and noble titles. These landowners were more open to new farming techniques that could earn them more profits. Second, the Enlightenment was discovering new ways to grow better crops. These two factors led to the four-field system that used all four fields rather than leaving one fallow. This had three advantages. First, it made previously useless and marginal land useful, thus expanding the amount of land under cultivation. Second, it used clover and turnips in the fourth field to maintain the soil's fertility. Finally, with the fourth field now in use, it was using all of the land every year rather than having to keep part of it fallow. These factors led to better crop production so that peasants could afford feed for livestock, leading to more meat and protein in the common people's diet. Unfortunately, this new and more efficient agriculture required large open tracts of land.

In the 1700's, the need for better agriculture and the need for large tracts of land for this new type of agriculture led to the Enclosure Movement, whereby wealthy landowners enclosed the common

lands so they could practice the four-field system. This created two effects that helped lead to the Industrial Revolution. First of all, the Enclosure Movement drove many people off their lands, forcing them to flock to the cities in search of homes and jobs. Also, this new kind of agriculture doubled food production, thus leading to dramatic population growth in England in the 1700's. The combination of population growth in the cities created the labor supply for Britain's textile mills when the Industrial Revolution began.

[Back to flowchart](#)

THE TECHNOLOGICAL BACKGROUND TO THE INDUSTRIAL REVOLUTION

[Back to flowchart](#)

Surviving Our Technological Adolescence

In the movie *Contact*, the government is conducting interviews to find just the right person to represent humans in our initial meeting with an advanced alien civilization. In the interview, they ask Jodie Foster's character, if she could only ask the aliens one question, what would it be.

Her answer: How did you survive your technological adolescence?

That in essence is the central question for our species and civilization.

The industrial revolution was the period where we entered our "technological adolescence", a period when we rapidly grew in power and a sense of independence without seeing the long-range consequences of our actions. In a sense, like teenagers, our prefrontal cortex had not developed (something which happens around age 25, magically making our car insurance rates go down).

Taking the adolescent analogy even further, we reached our sixteenth birthday in 1914, got our drivers license, and promptly ran the car into a tree (i.e., World War I in case you didn't get the reference). We thought we had learned our lesson, and then drove a faster car into a bigger tree in 1939 (i.e., World War II). So far, we've avoided totaling our newer and even faster car (and taking the entire tree out as well).

But we're more than a one-car family and there are various ways we can destroy the tree (e.g., environmental damage). Without going too far with this analogy, suffice it to say that, like the leap from walking to driving a car, we have gotten hold of a lot of power in a very short period of time and have a lot to learn about how to handle it.

The medieval roots of the Industrial Revolution. If new agricultural developments provided the backbone for supporting the Industrial Revolution, various technological innovations were its heart and soul. And the roots of those innovations and the cultural attitudes so vital for their formation go all the way back to the Middle Ages and the Cistercian monks. What triggered all this was the Cistercians' desire to get away from the evils of the world. This led them to found their monasteries in the wilderness away from civilization, but also away from any outside labor supply upon which they might rely. Being thrown back on their own resources, they rediscovered, probably in an old Latin or Greek text they were copying, the principles of applying water power with a waterwheel. The ancient Greeks had come up with this invention, along with the principles of steam power. However, the abundance of cheap human labor meant there was no real need for water or steam power in the ancient world. As a result, these principles lay largely unused until this time.

However, the Cistercians did need such principles and started experimenting with labor saving waterwheels, first applying them to the milling of grain into flour. Two later inventions dramatically expanded its uses. First, there was the cam, which was a piece of wood set on the drive shaft that struck anything in its way, such as a bellows or trip hammer, with each revolution of the waterwheel. Second, there was the crank that could convert the circular motion of the waterwheel into oscillating motion. These two developments led to applying waterpower to a multitude of tasks: They could drive rip-saws, bellows, and water pumps. They were connected to grinding stones for sharpening and polishing tools, weapons and armor. And they could power trip hammers for fulling cloth, crushing sugarcane, and pounding hemp and rags for rope and paper.

The number of mills that sprang up was astounding. William the Conqueror's census in 1089, the Domesday Book, listed no fewer than 5624 watermills in England alone. That was one mill for every 50 families and is estimated to have saved the average peasant wife two to three hours of work per day once the tedious task of milling grain was

mechanized. The main branch of the Seine River going through Paris had 68 mills. Another sixteen-kilometer stretch of stream had 30 such mills. Wherever rivers were slow, people built dams to increase the waterpower and floating mills to use that power. And where there were no rivers at all, they applied these mechanical principles to harnessing other types of energy, building tidal mills along the ocean and windmills (originally a Persian invention) on flat open land. By 1600, some 40 different types of industries were wholly or partially dependent on water or wind power, mechanizing such tasks as spinning silk, boring the barrels from cannons and muskets, and making gunpowder. In 1694, Louis XIV's main military engineer, the Marquis de Vauban, estimated that France had 80,000 flourmills, 15,000 industrial mills, and 500 iron mills.

As waterwheel technology spread across Western Europe, so did a growing awareness of how to exploit mechanical principles in general. In addition to harnessing the power of the tides and winds, Europeans were also developing better clocks (originally a Chinese invention). In fact, the clock would become the symbol of Europe's increasingly mechanistic view of the universe. However, while Europeans were harnessing time and parceling it out in discrete units of hours, minutes, and seconds, the clock was also more tightly structuring how Europeans lived their lives. This would be another important aspect of the Industrial Revolution as far as conditioning factory workers to the time clock and creating a more precise society.

It was Europeans' rising ability of how to exploit mechanical principles that led to three lines of technological development that together would culminate in possibly the most critical invention of the Industrial Revolution: the steam engine. Those lines of development had to do with mechanical ripsaws, larger bellows, and innovations in the textile industry.

The textile industry in Britain. Britain in the 1700's was the perfect example of the idea that necessity is the mother of invention. The triumph of the mercantile middle class in the English Revolution of the 1600's and the growth of European colonial empires, especially that of Britain, had created global trade links such as had never been seen

before. However, opening up such new vistas often creates problems, and that was the case with European textile production. Europe's higher standard of living made its goods and labor more expensive, which led to an influx of cheaper textiles from India that could undersell European, and particularly British, goods. In order to compete more successfully, British textile producers needed a cheaper and faster way to produce cloth.

The answer came with the invention of the more mechanized handloom (1733) which had a "flying shuttle" that quickly wove the weft thread in between the warp threads. This could double the speed of production, except for one other problem. The spinning wheel used to spin the thread for the loom was too slow. The solution came with two more inventions in the 1760's: the spinning jenny, which could spin seven threads at a time, and the water frame which could use water power to increase the speed of spinning and weaving even more. This series of inventions gave the British textile industry a tremendous boost, and soon textile mills were springing up on just about every available bit of river front property. Unfortunately, the amount of such property was limited, and soon profit hungry businessmen were looking for a new power source to drive their looms and spinning jenny's. Luckily, all this while a new power source had been emerging. That was the steam engine

Ripsaws and bellows, coal and iron. As mentioned above, one important application of the waterwheel was to drive larger bellows. What this made possible was hotter fires with which metal smiths could finally smelt iron. And that provided purer iron for building stronger boilers and steam engines.

Another important development was the water-powered ripsaw. This was a much more efficient way to cut timber, so efficient in fact that, by 1600, most of Britain was effectively deforested. Therefore, the English, largely without their primary heat source, wood (and charcoal processed from wood), had to find something else to burn. They found it in Britain's plentiful coal deposits.

One problem with coal is that it burns much less cleanly than charcoal, making it harder to come up with good iron. This was until 1709 when someone discovered a way to process coal into a cleaner and hotter burning substance known as coke. However,

it was not until 1783 that a smelting technique, known as rolling and puddling, was invented which worked the impurities out of iron and made it strong and cheap enough for widespread industrial use. With stronger and cleaner iron, people could make boilers able to withstand the higher steam pressures needed for more powerful steam engines. This of course was only relevant once the steam engine had been invented, which brings us to another problem with coal.

Unfortunately, most of Britain's coal was buried in deposits that required the construction of deep shaft mines. Eventually coal miners ran into that curse of all deep mines: water seepage. It was here that a crude steam pump was devised to give steam its first practical job. Unfortunately, this early pump was inefficient and burned nearly as much coal as was being mined. More efficient models were designed, notably that of Thomas Newcomen. But a truly efficient design did not come along until 1769 when James Watt introduced a practical two-chamber steam engine that made steam power economical to use in the mines.

Not only was steam power practical for the mines. It also found applications in the textile mills for those businessmen not lucky enough to have waterfront property and the free power that went with it. As a result, British textile production jumped by a factor of 30 times. With each passing year, the hissing, churning, and pumping of the steam engines rang louder in Britain's cities while the black smoke from burning coal steadily darkened its skies. The Industrial Revolution had been born.

The Waterwheel

Greek waterwheels went through various evolutionary phases. At first, they were laid out on a horizontal plane, which was only about 10% efficient. When they stood it up vertically and ran water under it as an undershot, efficiency improved to 20-30%. An overshot model with

the water coming down from above and adding the force of gravity further improved it to 50-70% efficiency.

In one workday (10 hours), a Roman water mill at Monte Cassino could grind 1500 Kilograms of grain, doing the work of 40 men. Similarly, a milling complex at Arles in Roman Gaul had 16 waterwheels that could mill enough grain to feed 80,000 people. Since the local population was probably only about 10,000, we figure the milling complex at Arles was the center of a vast redistribution network, indicating the large scale of trade in the Roman Empire.

Generally, however, ancient societies were not in favor of such labor saving technologies. For example, when someone approached the Roman emperor, Tiberius with an idea for a device that could do the work of forty men, Tiberius told him to keep it under wraps, since every such device would put forty men out of work and generate social turmoil. Therefore, little evidence survives of waterwheel technology from the ancient world. Luckily, monks, such as the Cistercians, preserved and revived the concept.

The original function of the waterwheel was to mill grain into flour, a tedious job typically done by women, (which may explain why mechanizing that one task wasn't seen as threatening to the social order). However, compared to the Roman Empire during the Pax Romana, medieval Europe was a sparsely populated demographic backwash in greater need of labor saving devices, especially for isolated monks up in the hills.

According to the Domesday census of 1085, there were already 5624 water mills in Saxon England, one for every 50 families. Such a device could save a woman 2-3 hours of hand-milling grain every day. No wonder that in Old English the Anglo Saxon word "Lord" meant loaf giver, probably referring to the fact that the peasants had to use the lord's mill and oven for milling and baking bread.

Unfortunately, the rotary motion of the waterwheel had limited applications, so the next

step was to transform that into an oscillating back-and-forth motion to operate devices like trip hammers and bellows. One innovation was the cam, a protrusion coming off the water wheel's drive shaft that upon each rotation would trigger a device. For instance, it could hit the lighter end of a trip hammer on a fulcrum lowering that end and in the process raising the hammer until the cam cleared the light end, thus releasing the hammer.

The other innovation was the crank, a bend in the main drive shaft attached to a vertical shaft that was also attached to something like a bellows. In the course of its rotation, the crank would drive the vertical shaft up and then down, thus operating the bellows in a continuous oscillating motion.

The beauty of all this was that it was harnessing an indefinite source of free energy that vastly multiplied people's productivity, and the medieval imagination ran wild applying these principles. Some of the jobs the Cam and crank helped mechanize were operating rip saws, bellows, and pumps, slitting and polishing metal, grinding glass, spinning silk, and pounding sugar, malt, hemp, flax (for linen), and rags (for paper).

In 1327, there were 130 fulling mills in England, a process that had been almost completely mechanized by 1400.

By the late 1200's, rag pounding to make paper was done by water-powered hammers. Between 1600 and 1763 the number of water powered paper mills grew from 38 to 350.

By 1600 some 40 different industries depended on water power: several steps in the manufacture of linen (e.g., separating the fibers, washing the cloth), threshing grain, operating lathes, drawing wire, slitting metal, boring holes into cylinders and cannon barrels etc and making gunpowder. By 1692, there were twenty-two powder mills in France.

Naturally, the waterwheel made riverfront property prime real estate. For example, there

were 30 water mills along a 16-kilometer stretch of the Seine River. Particularly valuable would be narrow areas, in a river, such as between bridge abutments where waterpower was especially channeled and concentrated.

Mill fever. By the thirteenth century, everyone and his uncle wanted a watermill. The numerous depictions of waterwheels in European art are evidence of their ubiquity. To increase the flow of slow rivers, they would build dams. Near Toulouse, there were 60 floating mills built around such dams in three groups. Unfortunately, such dams and floating mills interfered with navigation and often broke loose during floods, crashing into other boats on river front property and triggering lawsuits. As a result, the floating mills were replaced with 43 mills on the right bank.

Windmills were a perfect alternative to waterwheels in the Low Countries (modern Holland and Belgium) by the sea where the rivers were slow and sluggish, but the coastal breezes were brisk and continuous. The windmill was apparently a Persian invention from around the ninth century. Like the waterwheel, the first versions were horizontal. However, the vertical position was found to be superior, especially when they found a way to put the whole structure of the windmill on a hinge-post that could be turned in the most favorable direction. There were 120 windmills alone around the Flemish city of Ypres. In addition to milling grain and other duties, they were critical for pumping water out of the area, since it was so prone to flooding.

Tidal mills were typical of the growing medieval urge to exploit new energy sources. They were generally built along slow rivers close to the coast, some having dams that enclosed up to 13 acres of water. A tidal mill used different water pressures to function.

Another mechanical innovation was a horse-powered treadmill for threshing wheat.

Keeping Time and Time Keeping Us

While some of the earliest European clocks, such as the town clock in Prague, continued to chart the heavens for astrological purposes, Europeans scaled them down just to keep daily time.

Keeping time. If water, wind and tidal mills powered the age, clocks symbolized it. The first mechanical clock was built during the Sung Dynasty in China around 900 C.E. It was both an astrological and astronomical clock with seven faces to mechanically track the motion of the sun, moon, and five known planets at that time (Mercury, Venus, Mars, Jupiter, and Saturn). It was also a water clock with sophisticated machinery to regulate the flow of water in order to keep time. The clock was a royal monopoly to help emperors decide propitious times for acts of state, such as making war or peace. The emperors relied on it so much that, when an ambassador to the north reported that the heavenly bodies were not in line with the clock, the emperor replied that the clock was right and the sky was wrong.

Somehow, the idea and design of the Chinese clock made its way west, where an Italian, Giovanni di Dondi, built the most sophisticated clock of the Middle Ages between 1348 and 1364 (below). Like the Chinese clock, it had 7 faces showing the movements of the sun, moon and five known planets. It had no hourly dials, which he said were too simple, and was so sophisticated that it wasn't duplicated until the 1800's. One difference from the Chinese model was that his clock was weight driven with a mechanical escapement system since water froze in the wintertime. There is a working model of di Dondi's clock in the Smithsonian Institute.

Clock fever. While some of the earliest European clocks, such as the town clock in Prague,

continued to chart the heavens for astrological purposes, Europeans scaled them down just to keep daily time. The first clock recorded as just striking equal hours was in Milan in the early 1300's. From then on, it was a matter of pride for every medieval town to have its own clock tower, and they appeared in rapid succession in Genoa (1353), Florence (1354), Bologna (1356), Ferrara (1362), and Paris (1370).

Time keeping us. However, it was the clock in Paris that triggered a real turning point in Western Civilization when Charles V of France ordered the churches to ring their bells on the hour in coordination with the clocks, thus subordinating the Church's schedule to that of secular business. While Charles may have thought that he was capturing time, to a large extent time was capturing us, tying us to ever more precise schedules over the coming centuries so we know exactly when we have to get up, be at work, eat lunch, get off work, pick up the kids at soccer practice, and get to watch our favorite TV show. I could continue this list, but I don't have time.

Clocks and clock-like devices even started showing up in medieval art, indicating a more mechanistic view of the universe centuries before Newton. Along those lines, there was an emerging cultural mindset that was tuned into mechanical principles and how to exploit them.

Even more striking was an expectation, replacing the static unchanging view of the universe that such innovations would keep coming indefinitely. In short, people were starting to think in terms of something called progress.

"Never will we find truth if we content ourselves with what is already known... Those things that have been written before us are not laws but guides. The truth is open to all, for it is not yet totally possessed."--Gilbert de Tournai (c.1200-1284)

"Not all the arts have been found; we shall never see an end of finding them. Everyday one could discover a new art...It is not 20 years since there

was discovered the art of making eyeglasses which help one to see well, an art which is one of the best and most necessary in the world. And that is such a short time ago that a new art which had never before existed was invented..."--Fra Giordano (1306)

"We are as dwarfs mounted on the shoulders of giants, so that although we perceived many more things than they, it is not because our vision is more piercing or our stature higher, but because we are carried and elevated higher thanks to their gigantic size."--Bernard of Chartres (c.1115)

Steam

Hiero of Alexandria's aeropile (c.50 C.E.) was the first known steam engine. However, because of the abundance of cheap free and slave labor, the Greeks and Romans never exploited this invention's potential usefulness. It may also be that the metallurgy of the times couldn't create a boiler strong enough to do serious tasks.

The Newcomen Engine was used for pumping water out of mines. Unfortunately, it was so inefficient, it used up nearly as much coal as was being mined. The main problem with the Newcomen engine was that it had only one cylinder for heating and cooling, making it very inefficient, since so much energy was wasted in repeatedly heating and cooling that one chamber.

The major innovation of James Watts' engine was having two cylinders, one for heating and one for cooling. Which saved considerable amounts of fuel by not having to heat and cool the same cylinder.

The Evolution of the Textile Mill

The first new technology to revolutionize the textile industry was John Kay's flying shuttle

(1733). On wider looms, a second person was needed to take the shuttle with the weft thread across the warp threads. The wheeled shuttle (as Kay called it) could be thrown across the loom by one weaver at "a speed which cannot be imagined, so great that the shuttle can only be seen like a tiny cloud which disappears the same instant." (Roland de la Platière, Encyclopédie Méthodique)

Not only did the flying shuttle vastly increase the speed of weaving and cut in half the number of weavers needed per loom, it effectively doubled the number of looms that could be worked by a number of weavers, thus more than doubling production.

Now the weak link in production was the spinning wheel, which only spun one thread at a time, although we should keep in mind that it had revolutionized textile production in its own way when it was introduced in the Middle Ages.

In 1764 James Hargreave invented the spinning jenny, which could spin seven threads at once, although with the right amount of power, it could spin a hundred, or even a thousand, threads at a time. Four years later, Richard Arkwright solved that problem with a much larger spinning machine, the spinning frame. However, it was so big it had to be powered by a water wheel, and thus came to be known as the spinning frame or water frame.

Until now, both spinning and weaving had been handled in homes through a decentralized system known as the cottage industry. Women traditionally would do the spinning, while men did the weaving. However, the water frame was too big for individual cottages, so spinning was moved into factories that could make full use of adjacent waterpower. For the first time, families involved in making textiles were split up, the women working in factories and the men working on looms at home. Since these spinning factories looked like regular water mills for milling grain, they came to be called textile mills. For this reason, and his use of clocks to regulate workers, Arkwright is often credited with inventing the factory system.

From Looms to Computers

In 1728, a new weaving device, the Falcon's loom used the Frenchman Basile Bouchon's invention of perforated paper rolls, the holes operating as binary on/off switches to determine if a particular color thread was used in that row of fabric. A century later Joseph-Marie Jacquard invented an automatic loom (above) using punched cards to control the patterns in the fabrics in a similar way. Despite worker riots against the loss of jobs to these machines, virtually all industrial looms were using this system by 1900. Not only that, it was being applied to other industrial uses, such as riveting patterns on the large steel ships bringing millions of immigrants to America. Just in time, someone found another use for this concept.

The 1890 US census provided the impetus for another step toward inventing the computer. Because of the huge influx of immigrants, people figured the 1890 census wouldn't be finished before the 1900 census came around. To the rescue came the Hollerith machine. Using punch cards like those designed for Jacquard Looms, census takers would punch out chads on the appropriate places for numbers of family members, males, females, etc. Back at the census bureau, secretaries placed the card in an electronic machine with contact points for each space on the card. When the lever was lowered, only tabs for places with missing chads would complete the electronic circuit by touching the electrified plate underneath the card. This would automatically register the appropriate number on a counter. Like the Jacquard loom, this was using a basic binary, on-off, concept that is still central to computer design and still seen on standardized tests.

The history of mechanical calculators, forefathers of the computer, goes back to 1642 when Blaise Pascal created an adding machine, the Pascaline (bottom) that automatically carried digits from one position to the next. It had several dials that could be turned with a stylus. Underlying gears turned as each digit was dialed in, the cumulative total displayed in a window above the "keyboard". However, Pascalines remained little more than curiosity pieces in private parlors until the debut of Thomas De Colmar's Arithmometer in 1820. Able to add, subtract, multiply, and divide, it was the first commercially successful calculator, being the model for calculators into the 1900s.

The Englishman Charles Babbage (26 December 1791 – 18 October 1871) was obsessed with using the steam engine to power a device that would calculate navigational, celestial, and mathematical tables. From 1822 to 1849 he worked on the design for his Difference Machine, which could do four functions (add, subtract, multiply, and divide). He even got a grant from the British government, probably the first government grant for researching computers. Although he never built one, he is often considered the father of the computer. In 1991, to mark the bicentennial of Babbage's birth, a working Difference Machine (below) was built. To prove that it was feasible to build such a machine in the 19th century, the project used only the technology available then.

111. THE START OF THE INDUSTRIAL REVOLUTION IN BRITAIN (c.1750-1800)

Although the four-field system and steam engine provided the basic foundations for the Industrial Revolution, it took other factors combined with these to create this phenomenon. As it happened, Britain in the 1700's was the place where all these factors converged to make it the birthplace of the Industrial Revolution.

Much of Britain's favored position came from the English Revolution of the 1600's and the triumph of a wealthy middle class with both the money and willingness to invest in new ventures. This created five basic lines of development that together would trigger the Industrial Revolution. The first of was the new steam and textile technology. Second, there was the new agriculture and population growth creating both the labor force for the new industrial factories and the markets to buy their manufactured goods. The third factor was Britain's colonial empire, which provided raw materials for the factories as well as more markets for their goods.

Fourth was the development of a superior transportation system for getting raw materials to the factories and finished products to markets. Britain was especially favored in this respect, being an island with navigable inland rivers further enhanced by a well-developed system of canals. This, along with its colonial empire, prompted the British to build an excellent merchant marine for transporting its goods. Also, as the nineteenth century progressed, a new form of technology, the steam locomotive traveling on steel rails, would make overland transport increasingly economical and efficient for the first time in history.

The fifth and final factor was a large surplus of capital along with the willingness to spend it on new machines and technology. Central to this was the Bank of England, which encouraged investment, stability, and economic growth in both the public and private sectors. Consequently, when the machines and opportunities to exploit them came along, British businessmen were in by far the best position to take advantage of the situation, making Britain the banker of the world for the next century.

Two other factors also helped Britain. One was its excellent position as an island, which not only helped its trade, but also insulated it from continental wars. Also, Britain was blessed with extensive coal and iron deposits. By 1850, one-half

of the world's iron and a full two-thirds of its coal production would come from British mines. Along with providing the resources for producing steam power and heavy industrial machinery, it also triggered a dramatic migration from the more agricultural south to the industrial north where the coal and iron fields lay. In addition to coal and iron, Britain also had access to plentiful supplies of Scottish wool for its textile mills.

Later, Britain would rely on cotton from America. Once Eli Whitney's invention of the cotton gin (1793) solved the problem of cleaning the seeds out of the fiber, the southern United States became a primary cotton producer for British factories. However, the cotton gin had unforeseen and far-reaching consequences since it prolonged the life of slavery in the United States, making it a red-hot issue in American politics and a major factor leading to the American Civil War.

All these various factors (the new steam and textile technology, a large labor force, extensive markets at home and in its colonies, a superior transportation system, plenty of capital, extensive raw materials, and an excellent position for trade) combined to create a textile industry that could produce, transport, and sell vast quantities of cheap cloth by the late 1700's.

The result of all this was an industrial revolution of vast importance in a number of ways. For one thing, it would spawn the steam powered locomotive and railroads which would revolutionize land transportation and tie the interiors of continents together to a degree never before imagined. It would trigger massive changes in people's living and working conditions as well as the structures of family and society. And its momentum would generate a rapid-fire chain reaction of new technologies, a process that is still accelerating today and shows no signs of slowing down. Nor would these dramatic changes be confined to Europe. Rather, their power would spread across the globe to change the way the entire human species lives, for better or worse.

Canal Mania

Until railroads got their start in the 1830s, water was still the most efficient means of travel and transport. Therefore, to complement its excellent navigable rivers, Britain engaged in extensive canal building in the late 1700s and early 1800s. Particularly impressive were

aqueducts, such as the Barton, Chirk, and Pontcysyllte canals that carried cargo on boats over other rivers.

Canal mania spread to America in the early 1800s. While the best known was the Erie Canal, which connected New York City to Lake Erie via the Hudson River, making New York the primary port for the Great Lakes.

In addition, there was a system of canals stretching 280 miles across Pennsylvania using locks, dams, tow paths, and railroads (for towing boats). Charles Dickens wrote an account of traveling on this canal in 1842. He described the crossing of the Allegheny Portage Railroad: "*Occasionally the rails are laid upon the extreme verge of the giddy precipice and looking down from the carriage window, the traveler gazes sheer down without a stone or scrap of fence between into the mountain depths below,*" Overall, he described his trip across Pennsylvania as "*sufficiently disconcerting.*" Such a cumbersome journey was still better than carrying goods on foot until Railroads made it obsolete.

The Road to Hell is Paved with Gravel

Between the fall of the Roman Empire and the 1700s road conditions in Europe were abysmal. When it rained they could turn into a morass of mud. Otherwise they were full of potholes and ruts that were especially hazardous for passengers of stagecoaches with their high centers of gravity, killing many of them in stagecoach flips, although one man reportedly survived nine such flips. Ironically, another survivor of such a flip, William Huskisson, would be the very first railroad fatality.

Then John McAdam (1756-1836), invented a new kind of roadbed with large stones on the bottom with layers of progressively smaller stones on top. The smallest stones could only be 1" in diameter, the idea being the wear and tear of traffic would pack them together, as opposed to larger stones that would crack. Typically they had no binding, but sometimes tar would be used, thus giving rise to the term "tarmack". Macadamized roads, as they would be called, drained well with drainage channels to the side.

They were safe, and durable, vastly improving overland travel in Britain before the railroads.

Typically, the tedious work of stone breaking for Macadamized roads was done by convicts. Thus, the good intentions of his roads proved to be hell for convicts.

The Road to Hell is Paved with Cotton

Ironically, Eli Whitney invented the cotton gin in 1793 as a labor-saving device to expedite the removal of cotton seeds. Unfortunately, it proved a curse to African-Americans. Just as slavery was fading as an institution in the South, the massive new demands for cotton injected new life into that unfortunate institution and triggered a chain reaction of events that has plagued American history ever since.

In the 1800s cotton would replace linen as a primary fabric, since it can be washed more easily and frequently than linen, which has a tendency to crack and wear at the seams and creases. More frequent washing thus provided cleaner clothes, in particular eliminating lice, and probably improving overall public health.

112. RAILROADS AND THEIR IMPACT (c.1825-1900)

No invention of the 1800's played a more vital role in the Industrial Revolution than the steam locomotive and railroad, triggering the biggest leap in transportation technology in history. The technology central to railroads, the steam engine, needed two major improvements. First of all, a way had to be found to convert the oscillating motion of the steam engine to rotary motion so it could drive the locomotive's wheels. The solution came with James Watt's Sun and Planet gear, which connected the piston to the wheels somewhat off center to drive it forward. Secondly there was a need for stronger iron so boilers could create and withstand the pressure needed to drive steam locomotives. In 1783, the rolling and puddling process was invented, eliminating impurities in the iron and making it much stronger. In addition to creating much stronger boilers, it also led to stronger and cheaper iron rails on which the locomotives could ride.

Another catalyst for the invention of the locomotive was the loss of so many horses during the French Revolutionary and Napoleonic wars. This, along with the rolling and puddling method and Watt's Sun and Planet gear, sparked experiments leading to the first steam locomotive in 1804. However, it was not until the 1820's, when a properly running locomotive had been designed and the rolling and puddling technique had advanced and become widespread enough to make good cheap rails possible, that the first railroads were born.

In 1825, the Stockton and Darlington Railroad carried the first commercial freight of any railroad in history. Five years later, the Liverpool and Manchester Railroad opened operations carrying passengers as well as freight. This quickly sparked a virtual mania for building railroads in Europe and the United States after 1830. The 1800s saw incredible growth in the miles of track being laid. In 1830, Britain had only 95 miles of track. That figure had grown to 1500 miles by 1840 and 6600 miles by 1850. By contrast, Europe in 1850 had only 8000 miles of track. However, after 1850 Europe and the United States rapidly gained on Britain. By 1890, Britain had 20,000 miles of track, while Germany had 26,000 miles and the United

States had 167,000 miles. Even Russia had 48,000 miles of track by 1900, although that was spread out over a vast area.

Such rapid expansion had both political and economic effects. Politically, the power of the state grew considerably. For one thing railroads were expensive to build, leading governments to finance them directly or through massive land grants. Also, everyone wanted railroads to pass through and benefit their regions. At first, this was impractical, and governments often had to step in and decide where the main trunk lines should be laid before less profitable branch lines could be developed. Finally, standard gauges (track sizes) and safety standards had to be set so that different railroads could easily link up and run their trains on other companies' tracks without crashing into one another. Naturally, each railroad wanted to avoid the expense of adapting its own gauge to another company's standard, making it necessary for the government to step in and impose a standard gauge and safety practices. Therefore, as railroads unified their nations economically, the governments directing their development unified their nations politically and increased their own power.

Railroads cut travel time by 90% and dramatically reduced freight costs with three important economic results. First, they made possible the settlement and development of continental interiors. For example, in 1869 the first transcontinental railroad across North America was completed, transforming an arduous and dangerous journey of months into an easy trip of a few days. This linked the countryside more tightly to the cities, production areas to markets and raw materials, and continental interiors to coastlines and waterways. Second, farmers switched from raising subsistence crops to cash crops better suited for their local soils, thus increasing crop yields dramatically. They could then sell the crops, buy the food needed to feed themselves, and still have money for buying consumer goods. Finally, areas previously isolated during famines could now be supplied, leading to fewer deaths from hunger and starvation and corresponding increases in population.

With factories more closely connected to markets and the larger population of potential consumers, many more people could afford consumer goods. This stimulated sales, providing more jobs,

increased production, and lower prices. With business booming, companies developed new products, triggering a virtual explosion of new technological advances, inventions, and consumer products in the latter 1800's. All these advances led to a higher standard of living, which further increased the consumer market, starting the process all over again.

By 1900, railroads had virtually revolutionized overland transportation and travel, pulling whole continents tightly together (both economically and politically), helping create a higher standard of living, the modern consumer society, and a proliferation of new technologies. Although airplanes and automobiles would continue this revolution, it was the railroad that paved the way.

Getting on Track: Solving Various Technical Problems

Stationary steam engines were an early method for hauling loads up steep inclines until locomotives became more powerful. One such engine was used on the last leg of the Charleston-Hamburg line in South Carolina.

Another issue was wheel design. There were two competing designs: flanged wheels that overlapped the top of a flat rail and flat wheels kept on the rail by an L-shaped rail. Flanged wheels with the treads coned down to the outside managed curves better because the momentum of the turn would shift the outer wheel, which has a greater distance to travel, to its larger diameter compared to the inner wheel that has shifted correspondingly to its smaller diameter. Therefore, one rotation of the “larger” outer wheel will take that wheel farther than one rotation of the “smaller” inner wheel, thus compensating for the greater distance to travel on that curve.

Couplers. Early train cars were joined with chains that jerked passenger's necks until the more stable link-and-pin coupler was adopted from the U.S. However, railroad workers had to manually put in or lift out the pins to couple or uncouple the cars, running the risk of getting a hand crushed if the train moved as they guided the link into the socket of the second train car.

One side effect of the injuries caused by the link-and-pin system of coupling was the increased development and availability of prosthetic limbs. Companies that manufactured prosthetic limbs especially advertised in railroad journals and would list of all the railroads that had purchased their products.

In 1873, the more efficient and automatic Janney coupler was patented, which automatically coupled and uncoupled the cars. This saved a lot of railroad workers' limbs, but didn't help business for prosthetic limb companies.

The Birth of British Railroads

The Frenchman, Nicholas Cugnot (below), probably deserves credit for the first steam locomotive. He successfully tested his 3-wheeled steam car in Paris 1769, getting it up to six miles per hour. Unfortunately, with the crowd urging him to go faster, he pushed it up to nine miles per hour, whereupon it either exploded or he ran it into a wall (or maybe it ran into a wall and exploded). Either way, Cugnot was arrested and jailed as a madman.

In Britain, there were concerted efforts by a number of men to come up with a steam locomotive. William Murdock who built a working locomotive in 1784 that ran away from him one night and scared the local vicar who thought it was work of the Devil. Murdock also pioneered gas lighting. No telling what people thought of that.

George Stephenson's first successful locomotive, built in 1804, could travel 4 miles per hour.

The Rainhill Trials were held in 1825 to determine which method (stationary engines pulling trains by ropes, locomotives, horses, etc.) was best to use on the new railroads. The winner

had to haul 20 tons of freight at 10 miles per hour for a prize of £550. Four locomotives and one *cyclopede* (a horse running on a treadmill) competed. The winner was George Stephenson's *Rocket* after two engines broke down, and a third didn't make the required speed.

The first train fatality occurred on the maiden run of the Liverpool and Manchester Railroad in 1830 (above), a gala event that involved eight trains, each carrying 100 passengers, including the Duke of Wellington. William Huskisson, a Member of Parliament, upon stepping off one train when it stopped for water was immediately hit by the *Rocket* on an adjacent track. George Stephenson personally drove Huskisson on a train to get medical help, traveling at the unheard of speed of thirty-six miles per hour. But it was too late for Huskisson, who died an hour later. The Duke of Wellington was so upset that he didn't ride another train until 1843 when he accompanied Queen Victoria on a trip.

Hazards and Humbug About Railroads

Opposition to railroads did exist for a number of reasons:

- A famous race between the Tom Thumb and a horse drawn train showed skeptics the superiority of the horse.
- Religious people, considered the locomotive, with its fire and brimstone, the devil's work.
- Doctors said speeds over 15 miles per hour would suck the air out of your lungs.
- Farmers claimed cows and chickens wouldn't give milk or lay eggs.
- Others claimed flames from the locomotive would ignite cottage and hay stacks.
- Some feared the locomotive's pollution would end all natural life.
- When some mountain people first heard a train whistle, they went out to trap or kill the mysterious beast.

The steam locomotive did have its hazards. An Engineer on the Charleston-Hamburg line, annoyed by the hissing of the steam engine's safety valve, closed it, causing the steam pressure to build up and the engine to explode.

The hazards of train travel (especially in dark tunnels) included mischievous conductors, drunks, thieves, and "mashers" who would steal kisses from unsuspecting women. Ladies were encouraged to carry hatpins, so any man who got fresh would get his eye poked out.

Another hazard of train travel included card sharks whose trickster ways bilked many an innocent passenger of his carrying cash. One railroad even paid a particularly notorious gambler \$25,000 not to ride their trains.

There were also economic casualties, such as local craftsmen and small-scale industries competing with cheaper mass produced industrial goods and local fairs and peddlers whose businesses were hurt by mail order catalogues. Waterway companies also lost business to the much faster and increasingly cheaper railroads.

Train wrecks were another real hazard, especially as locomotives got faster and more powerful. By the late 1800s, the average speed cruising speed of a locomotive was 40 miles per hour, with top speeds of 60-70 miles per hour. In 1893 a locomotive set a new speed record of 112.5 miles per hour.

An even greater hazard was steamboat wrecks along rivers. Riverboats were made of wood, which made them flimsy and vulnerable to fires, especially in an age when smoking was ubiquitous and unrestricted. Along with the usual wrecks caused by fires and hitting rocks and sandbars, riverboats faced the ongoing danger of boiler explosions that could blow them to smithereens. The worst such disaster occurred just weeks after the Civil War on the night of April 27, 1865, when the boilers of the steamer, *Sultana*, exploded, (above) killing 1,547 passengers, most of them returning prisoners of war. By comparison, 1,517 people perished with the *Titanic*.

Setting Standards

One day two railroads met at Gloucester, one with a gauge (track width) of 4'8.5" and the other with 7'4". Obviously, neither company wanted to modify its tracks, so a third party, the national government, had to step in to ensure that railroads across Britain could easily connect and use each others' tracks. Therefore the British government set the standard gauge at 4'8.5" in 1846.

Some countries, like Australia still don't have standard gauges. Neither did the Confederacy during the American Civil War, a factor that contributed to its ultimate defeat.

The Scotsman, Samuel B. Morse invented the telegraph to coordinate trains, hopefully to prevent train wrecks like the one above. Similarly, block signaling to ensure there was only one train on a stretch of track between two signal boxes was established in 1875.

The creation of time zones

Before high speed railway travel and telegraph communication, there was no real need or way to coordinate clocks over large distances. Instead, each town set its clocks based on when the sun was at its highest point over that town. Different towns' clocks and watches would vary by a few minutes each when traveling east or west, but at such slow speeds, it didn't matter.

However, in the 1800s, railroads wanted to create precise timetables for their passengers, which required coordinating clocks over long distances. Luckily, the telegraph could provide instantaneous communication for simultaneously setting clocks at different locations. On December 1, 1847, British railways established the first standard time zone for Britain, based on Greenwich Mean time, which had been set as a standard nautical reference point in 1675.

By 1855, 98% of Britain's public clocks were based on Greenwich Mean Time, although the government didn't officially establish this as the standard time until 1880. Some clocks from the time continued to have two minute hands, one for standard time and one for local time.

In the US, things were a bit more complicated, since each railroad went by its own time, usually based on that railroad's headquarters. Some stations had a different clock with a different time for each railroad serving that station. For instance, Pittsburgh's main railroad station had six clocks with six different times. On November 18, 1883 the railroads inaugurated what constitute the current time zones in the U.S. for the railroad stations. Within a year 85% of the nation's major cities were on standard time. In 1918 Congress passed the Standard Time Act, putting the whole nation on standard time zones.

A single global time zone was proposed at the October 1884 at the International Meridian Conference held in Washington, D.C., but its delegates didn't feel they had the authority to impose it. Another idea, which was eventually adopted, was starting the day at midnight instead of noon.

In 1976, Maharishi Mahesh Yogi proposed a global system of 12 time zones (below) so that the "golden hue of Heaven on Earth will dawn with the sunrise in every time zone, and every nation will enjoy a greater good fortune day by day, around the year, around the globe."

113. THE SOCIAL IMPACT OF INDUSTRIALIZATION

Right and left a multitude of covered passages lead from the main street into numerous courts, and he who turns in thither gets into a filth and “Right & left a multitude of covered passages lead from the main street into numerous courts, & he who turns in thither gets into a filth & disgusting grime, the equal of which is not to be found - especially in the courts which lead down to the Irk, and which contain unqualifiedly the most horrible dwellings which I have yet beheld. In one of these courts there stands directly at the entrance, at the end of the covered passage, a privy without a door, so dirty that the inhabitants can pass into & out of the court only by passing through foul pools of stagnant urine & excrement. This is the first court on the Irk above Ducie Bridge - in case any one should care to look into it. Below it on the river there are several tanneries, which fill the whole neighbourhood with the stench of animal putrefaction. Below Ducie Bridge the only entrance to most of the houses is by means of narrow, dirty stairs & over heaps of refuse and filth. The first court below Ducie Bridge, known as Allen's Court, was in such a state at the time of the cholera that the sanitary police ordered it evacuated, swept, & disinfected with chloride of lime... At the bottom flows, or rather stagnates, the Irk, a narrow, coal-black, foul-smelling stream, full of debris & refuse, which it deposits on the shallower right bank.

“In dry weather, a long string of the most disgusting, blackish-green, slime pools are left standing on this bank, from the depths of which bubbles of miasmatic gas constantly arise and give forth a stench unendurable even on the bridge forty or fifty feet above the surface of the stream. But besides this, the stream itself is checked every few paces by high weirs, behind which slime and refuse accumulate and rot in thick masses. Above the bridge are tanneries, bone mills, and gasworks, from which all drains and refuse find their way into the Irk, which receives further the contents of all the neighbouring sewers and privies. It may be easily imagined, therefore, what sort of residue the stream deposits. Below the bridge you look upon the piles of debris, the refuse, filth, and offal from the courts on the steep left bank; here each house is packed close behind its neighbour and a piece of

each is visible, all black, smoky, crumbling, ancient, with broken panes and window frames...

“Above Ducie Bridge, the left bank grows more flat and the right bank steeper, but the condition of the dwellings on both banks grows worse rather than better. He who turns to the left here from the main street, Long Millgate, is lost; he wanders from one court to another, turns countless corners, passes nothing but narrow, filthy nooks and alleys, until after a few minutes he has lost all clue, and knows not whither to turn. Everywhere half or wholly ruined buildings, some of them actually uninhabited, which means a great deal here; rarely a wooden or stone floor to be seen in the houses, almost uniformly broken, ill-fitting windows and doors, and a state of filth! Everywhere heaps of debris, refuse, and offal; standing pools for gutters, and a stench which alone would make it impossible for a human being in any degree civilised to live in such a district... Immediately under the railway bridge there stands a court, the filth and horrors of which surpass all the others by far, just because it was hitherto so shut off, so secluded that the way to it could not be found without a good deal of trouble... Passing along a rough bank, among stakes and washing-lines, one penetrates into this chaos of small one-storied, one-roomed huts, in most of which there is no artificial floor; kitchen, living and sleeping-room all in one. In such a hole, scarcely five feet long by six broad, I found two beds - and such bedsteads and beds! - which, with a staircase and chimney-place, exactly filled the room. In several others I found absolutely nothing, while the door stood open, and the inhabitants leaned against it. Everywhere before the doors refuse and offal; that any sort of pavement lay underneath could not be seen but only felt, here and there, with the feet. This whole collection of cattle-sheds for human beings was surrounded on two sides by houses and a factory, and on the third by the river, and besides the narrow stair up the bank, a narrow doorway alone led out into another almost equally ill-built, ill-kept labyrinth of dwellings....

“. . . Here, as in most of the working-men's quarters of Manchester, the pork-raisers rent the courts and build pig-pens in them. In almost every court one or even several such pens may be found, into which the inhabitants of the court throw all refuse and offal, whence the swine grow fat; and

the atmosphere, confined on all four sides, is utterly corrupted by putrefying animal and vegetable substances....

“Such is the Old Town of Manchester, and on re-reading my description, I am forced to admit that instead of being exaggerated, it is far from black enough to convey a true impression of the filth, ruin, and uninhabitableness, the defiance of all considerations of cleanliness, ventilation, and health which characterise the construction of this single district, containing at least twenty to thirty thousand inhabitants. And such a district exists in the heart of the second city of England, the first manufacturing city of the world. If any one wishes to see in how little space a human being can move, how little air - and such air! - he can breathe, how little of civilisation he may share and yet live, it is only necessary to travel hither. True, this is the Old Town, and the people of Manchester emphasise the fact whenever any one mentions to them the frightful condition of this Hell upon Earth; but what does that prove? Everything which here arouses horror and indignation is of recent origin, belongs to the industrial epoch.”

From Friedrich Engels, *The Condition of the Working-Class in England in 1844* (London: Swan Sonnenschein & Co., 1892), pp. 45, 48-53

Today we see the Industrial Revolution as being responsible for the higher standard of living we enjoy. This, of course, is true, but there was a great and, at times, appalling, price paid in human suffering to attain this standard of living. From the start, industrialization meant the transformation of countries' populations from being predominantly rural to being predominantly urban. In England, this involved the migration of millions from the agricultural south to the cities springing up near the coal and iron fields in the north. The population of Manchester, England grew from 25,000 in 1772 to 303,000 by 1850. Liverpool's population rose from 80,000 to 397,000 in the first half of the nineteenth century. Other cities told similar stories of incredible growth. Overall in Britain, the number of cities with populations of 50,000 or more rose from 3 in 1785 to 31 in 1860. By 1850, Britain had become the first nation in history to have a larger urban than rural population. Other countries would soon follow suit.

These early industrial cities created problems in three areas: living conditions, working conditions, and the social structure. First of all, cities built so rapidly were also built shoddily. Tenement houses were crammed together along narrow streets, poorly built, and incredibly crowded. Whole families were packed into attics, cellars, or single rooms, with one house holding 63 people in 7 rooms. Sanitation was virtually non-existent, making clean water a luxury reserved for the rich. Open sewers ran down streets carrying water fouled with industrial and human waste. Diseases such as cholera, typhoid, typhus, and tuberculosis often reached epidemic proportions. Add to these problems air pollution and malnutrition, and one gets a picture of incomparable human misery. Alcoholism, drug abuse, crime, and prostitution were natural outcomes of having to endure these conditions.

Away from home, working conditions were even worse. Depending on the hours of sunlight, the workday could extend up to 19 hours a day, six days a week. The work itself was hard, boring, and tedious. Conditions around the steam engines and in the mines were hot and at times extremely dangerous. In the absence of safety devices, machines often tore off fingers, hands, and even arms. Mine shafts would occasionally explode or cave in, trapping and killing hundreds of workers deep within the earth.

Despite all this, there were often long lines of the unemployed waiting for any available jobs. This surplus of labor kept wages excessively low. As a result, families had to send their women and even their children to work in the factories just to make ends meet. In fact, women and children were preferred as workers because they could be paid less while being worked harder. Occasional depressions in the economy could lead to whole industries shutting down. This left thousands of families with no jobs and no public welfare to see them through such hard times. Even medieval serfs had been assured some rights to a living off their lands, which was more than these people could often enjoy.

The Industrial Revolution also upset old social patterns of life and family. Under the old domestic system of cottage industries, peasants worked in their own homes, produced at their own rates, and were paid accordingly. Under the new factory system, laborers worked in the factories owned by

bosses whom they rarely, if ever, saw. They had to be at work precisely on time and work at the much faster pace of the machines. Nevertheless, they were paid by the hour, not according to their productivity, since that was cheaper for the owner.

Previously, the farm, home and the workplace were one and the same, with men and women sharing in many of the same tasks. In the industrial city, there was a separation of home and workplace and a correspondingly greater separation of the roles men and women played. In middle class families, men went to work while women stayed home with the children. In working class families, men, women, and children all went to work, but usually to separate places. For both middle and working class families, these were added strains that pulled the family apart.

Although the nuclear family had generally replaced the extended family in European society since the Black Death (largely in order to keep from splitting up family lands), there was still a network of close friends and relatives in the village providing each other mutual support. It is true that, when individual families moved to the city, they left behind the support network of the villages, often living in isolation and having little or no support from their neighbors. However, softening the effects to an extent was the tendency for people to follow friends and family to the same cities and neighborhoods and settle in the same crowded tenements, thus maintaining some sense of community.

It would be after World War II that the truly isolated nuclear family emerged when a housing shortage triggered a new phenomenon, the suburbs, that provided millions of small affordable single-family homes to young couples. Instead of the community of the village or even the crowded tenements, each nuclear family lived in its own private home in isolation from its neighbors (who were usually complete strangers), separated by property lines, hedges, and fences.

It is no wonder the growing numbers of people left helpless and destitute by the rapid changes of industrialization often turned to crime, alcoholism, and drugs. All this did not go unnoticed, and reform movements arose from three directions. Some reformers were genuinely concerned industrialists

such as Robert Owen and W. H. Lever, who built model communities in which their workers could live and work. Other reformers were liberal politicians trying to alleviate the sufferings of the masses or conservative politicians trying to avert social revolution caused by such misery. Together such politicians enacted legislation that gradually eased the plight of the working class, such as the Factory Act of 1833, which limited the use of child labor, and the Factory Act of 1850, which limited women and children to workdays of ten and a half hours.

However, many workers felt that for real progress to be made, they would have to work for it themselves. That involved organizing into trade unions, the very existence of which was illegal until 1824. Even then, they could only exist as mutual aid societies to provide their members with insurance against sickness and injury. Not until 1871 could British unions represent their members' grievances and actively work for reforms. The struggle for those reforms was a long, hard, and often violent one. However, by the end of the nineteenth century, trade unions had made substantial progress toward improving the living and working conditions that industrial workers had to endure.

The standard of living for workers in the early Industrial Revolution was certainly horrible, but it did improve in the course of the nineteenth century. Two types of statistics tell us this. First of all, the overall population of Europe rose dramatically from some 187,000,000 in 1800 to 466,000,000 by 1914. Add to that another 60,000,000 who emigrated to other continents, and one gets the distinct impression that the overall standard of living in Europe was getting better.

Another figure telling a similar story of progress is the average life expectancy of Europeans during this time. In 1800, most people could expect to live around 30 years or less, depending on their social class. By 1900, the average life expectancy had risen about fifty per cent to 45 years. Better living conditions and nutrition, public sanitation, and great advances in medical science were all responsible for this jump. However, the price those early generations of factory workers paid for this progress and our own comfortable life styles was a terrible one indeed.

Children's Changing Status in the 1800s

Child labor was among the most blatant abuses of the early industrial revolution, since children were so easy to exploit. Fourteen-hour workdays were common. Orphans and children on the street were rented out to factories, which also made for fewer mouths for orphanages or poor families to feed. In 1767, a law was passed giving money to company nurses for every child laborer who had survived another year of factory or mine work.

Following is a rather grim account of the Death of a girl in a factory:

“A girl named Mary Richards, who was thought remarkably handsome when she left the workhouse, and, who was not quite ten years of age, attended a drawing frame, below which, and about a foot from the floor, was a horizontal shaft, by which the frames above were turned. It happened one evening, when her apron was caught by the shaft. In an instant the poor girl was drawn by an irresistible force and dashed on the floor. She uttered the most heart-rending shrieks! Blincoe ran towards her, an agonized and helpless beholder of a scene of horror. He saw her whirled round and round with the shaft - he heard the bones of her arms, legs, thighs, etc. successively snap asunder, crushed, seemingly, to atoms, as the machinery whirled her round, and drew tighter and tighter her body within the works, her blood was scattered over the frame and streamed upon the floor, her head appeared dashed to pieces - at last, her mangled body was jammed in so fast, between the shafts and the floor, that the water being low and the wheels off the gear, it stopped the main shaft. When she was extricated, every bone was found broken - her head dreadfully crushed. She was carried off quite lifeless.”

In the coal mines, younger children, known as “thrusters”, would push and pull carts of coal through a mine shaft only 20 inches high, while even younger trappers about six years old, would open blast doors, meant to contain coal dust explosions, for them. Girls as young as six would coal out of mines in Scotland, having to climb 370 feet of ladders, the coal being in baskets on their backs and with straps around their foreheads. Each trip was called a rake, and girls

had to make between ten and fourteen rakes a day.

A commission in Nottingham in 1850 reported that children were “dragged from their squalid beds at 2, 3, or 4 o’clock in the morning and compelled to work for bare subsistence until 10, 11, or 12 at night, their limbs wearing away, their frames dwindling, their faces whitening and their humanity absolutely sinking into a stone-like torpor, utterly horrible to contemplate.”

However, conditions did improve for children. Public outrage led to a series of laws limiting the age and hours that children could work in mines and factories. Meanwhile, the nation state was claiming more of the children’s time in public schools to make them better citizens. Another factor was a changing, and often idealized, view of childhood as a separate and more innocent stage of human development, especially among the emerging middle class that didn’t need to send their children to work in the factories. This increased emphasis on children’s welfare led to a children’s industry producing a profusion of reading primers, children’s magazines, and toys.

Charles Dickens’ Description of Coketown, a fictional industrial city

"It was a town of red brick, or of brick that would have been red if the smoke and ashes had allowed it; but as matters stood it was a town of unnatural red and black like the painted face over which interminable serpents of smoke trailed themselves for ever and ever, and never got uncoiled. It had a black canal in it, and a river that ran purple with ill-smelling dye, and vast piles of buildings full of windows where there was rattling and a trembling all day long, and where the piston of the steam-engine worked monotonously up and down like the head of an elephant in a state of melancholy madness. It contained several large streets all very like one another, and many small streets still more like one another, inhabited by people equally like one another, who all went in and out at the same hours, with the same sound upon the same pavements, to do the same work, and to whom every day was the same as yesterday and

tomorrow, and every year the counterpart of the last and the next...

"You saw nothing in Coketown but what was severely workful. If the members of a religious persuasion built a chapel there-- as the members of eighteen religious persuasions had done-- they made it a pious warehouse of red brick, with sometimes (but this is only in highly ornamental examples) a bell in a birdcage on the top of it.... All the public inscriptions in the town were painted alike, in severe characters of black and white. The jail might have been the infirmary, the infirmary might have been the jail, the town-hall might have been either, or both, or anything else, for anything that appeared to the contrary in the graces of their construction. Fact, fact, fact, everywhere in the immaterial. The M'Choakumchild school was all fact, and the school of design was all fact, and the relations between master and man were all fact, and everything was fact between the lying-in hospital and the cemetery, and what you couldn't state in figures, or show to be purchaseable in the cheapest market and saleable in the dearest, was not, and never should be, world without end. Amen." --From *Hard Times* by Charles Dickens

Working Women

Since the first major industry was making textiles, it was natural that women made up a large part of the workforce, since they were so involved with that activity at home, both for domestic consumption and the cottage industry system that had dominated textile production since the later Middle Ages. Besides having nimble fingers for spinning and weaving, they were also easy to exploit. Therefore they found work in other industries, including coal mining. Following is a description of working conditions in a coalmine given by a woman named Betty Harris. She was 37 years old at the time:

"I was married at 23, and went into a colliery (coal mine) when I was married. I used to weave when about 12 years old; can neither read nor write...I am a drawer, and work from 6 in the morning to 6 at night. Stop about an hour at noon to eat my dinner; have bread and butter for dinner; I get no drink. I have two children, but they are too young to work. I worked at

drawing when I was in the family way. I know a woman who has gone home and washed herself, taken to her bed, delivered of a child, and gone to work again under the week.

"I have a belt round my waist, and a chain passing between my legs, and I go on my hands and feet. The road is very steep, and we have to hold by a rope; and when there is no rope, by anything we can catch hold of. There are six women and about six boys and girls in the pit I work in; it is very hard work for a woman...

"My cousin looks after my children in the day time. I am very tired when I get home at night; I fall asleep sometimes before I get washed. I am not so strong as I was, and cannot stand my work so well as I used to. I have drawn till I have bathed skin off me; the belt and chain is worse when we are in the family way. My feller (husband) has beaten me many a times for not being ready. I were not used to it at first, and he had little patience.

"I have known many a man beat his drawer. I have known men take liberties with the drawers, and some of the women have bastards."
From *Great Britain, Parliamentary Papers, 1842, Vol. XV, p. 84, and ibid., Vol. XVII, p. 108*

Sexual harassment is nothing new to our times. Neither is getting caught, although women were much more vulnerable to this kind of treatment and susceptible to being blamed for it as well. If a woman refused to go along with her boss's demands, she would probably be fired. If she did give in to his advances and got pregnant, she would also probably be fired.

The Triangle Shirtwaist Factory Fire (3/25/1911) in New York City was one of the most notorious examples of disregard for the safety and lives of the workers. In order to keep the workers, mostly women and girls, from leaving early, the factory's owners locked them inside. When a fire broke out, ladders could only reach the sixth floor, dooming those above. A total of 146 workers died and another 71 were injured. This fire did spur the U.S. government to implement stricter safety standards for industries.

Life and Death in the Early Industrial Revolution

Living conditions in industrial cities were, if anything, worse than working conditions. Poisonous dyes and plaster of Paris were added to food to make it seem more substantial and nutritious than it really was. Sewers were open ditches running down the middle of streets, while drinking water had brown particles floating in it.

There were no parks or trees. Because of window taxes, there were few windows and virtually no fresh air in houses, a mixed blessing, given the air pollution. Tenements would have up to seven people crammed into a room.

Epidemics of cholera, tuberculosis, typhoid, and diphtheria would rage through cities, while death rates from diseases such as smallpox, measles, scarlet fever and whooping cough were four times higher in industrial cities than in the countryside. Deaths from convulsions were ten times higher. An estimated 94% of urban populations died from infectious diseases. Child mortality before age five was 47%.

Not surprisingly, drugs, alcoholism and crime were major problems. Street gangs, such as New York City's Bowery Boys, often ruled the streets. Manchester, England had 1600 bars where workers, even children, could kill or dull the pain. There were also 26,000 opium apothecaries in Britain. Since opium from India was cheaper than food (and legal), some mothers would dose their children to keep them from crying all night from hunger pangs. When Marx said religion was the opiate of the masses, he knew his audience well.

The Company Store. Many factories and mines sprang up in relatively isolated places, although towns and cities would often grow up around them. Therefore the only source for supplies the workers had was the company store, which typically overcharged customers even for basic necessities. Since workers often came up short on the bill, the company would give them credit towards the next paycheck, which, of course, would not be enough to cover that week's

groceries and supplies, let alone pay the outstanding debt the employees owed. Thus the bill would climb higher and higher with each passing week, with the employees falling deeper and deeper into debt. One other thing: employees couldn't quit and leave until they had paid the debt, thus trapping them into a sort of industrial serfdom. If they did run away, the company had the right to form a posse and drag them back.

*You load sixteen tons, what do you get
Another day older and deeper in debt
Saint Peter don't you call me 'cause I can't
go
I owe my soul to the company store
--'Sixteen Tons' by Tennessee Ernie Ford*

"*Canary in a coal mine*" refers to a practice of bringing a canary into a mine shaft to determine if it was safe for the miners, the primary hazard being toxic gases (such as methane and carbon monoxide). Since canaries are more sensitive to such gases, if they got sick, that was a signal for the miners to get out. Later on, better ventilation systems, besides saving coal miners' lives, also saved the lives of thousands of canaries, much to the chagrin of canary breeders.

The Humphrey Lamp. Another hazard in coalmines was the build-up of coal dust in the air to such a concentrations that a flame or spark could ignite a deadly explosion. (Build-up of flour dust in watermills and windmills presented a similar hazard.) Then Humphrey Davy (1778?-1829) invented the Humphrey Lamp, which used gauze to filter out combustible gases while letting in oxygen to feed a flame, thus reducing the incidence of mine explosions at certain levels of concentration. As a result mine owners could send miners into greater concentrations of coal dust where the explosions would be even more deadly.

One sees similar disregard for the miners' lives in present-day China, where an estimated 40,000 miners are killed each year, it being cheaper to pay minimal death benefits to families than to institute stricter, but more expensive, safety regulations.

Labor's Long Hard Road to Dignity

Robert Owen. Among factory owners who worked for reforms and a more just society was Robert Owen, who established a cotton mill and community of 2500 people in New Lanark, Scotland in 1786. Owen wanted to create a utopian socialist society based on the principles of equal work, equal pay, and no ownership of private property. In that spirit, he reduced work hours, and created safer working conditions in his factories. He also provided his workers decent housing, with plenty of windows for fresh air and even flower boxes.

Owen also worked to combat the worst abuses of child labor, establishing a minimum age of ten years for his workers, young by our standards, but quite progressive back then. Along those lines, he worked to improve the lot and education of New Lanark's 500 children at his New Institution for the Formation of Character (below), which replaced books with more physical activities such as singing, dancing, marching, basic geography, and three hours a day of free play in an open playground. Owen's institution was the inspiration for Great Britain's inaugural pre-school program that opened in New Lanark in 1816.

Owen's experiment was both successful and profitable, generating worldwide interest. However, he was disappointed that his model didn't spread more quickly throughout Britain, so he moved to New Harmony, Indiana in 1824 to establish a utopian commune. Among his more radical ideas was promoting equal rights for women. Although initially successful, inspiring fifteen other Owenite communities to spring up, the experiment at New Harmony ultimately collapsed along with all its imitators, largely because of infighting over various policies. In Owen's case, it was also the result of a business partner absconding with the community's profits.

Relief provided by the Salvation Army included beds that eerily represented coffins. They were designed to help the poor but discourage prolonged stays.

Leading the way in legislative reforms was a series of laws gradually restricting exploitation of children. In 1833, a new law dictated that no one under age nine could work in the mines or factories, while those between nine and fourteen could only work 68 hours per week. This was further regulated in 1848 when no one under ten could work in the mines or factories and those between ten and fourteen could only work on alternate days, and even then for only twelve-hour shifts with two hours off for lunch. Two years later, a maximum shift of ten and a half hours was mandated for children and women. Soon, men were agitating for similar hours, so that by 1900 the ten-hour shift was standard in Britain.

Of course, passing a law and enforcing it are two separate things, so that widespread labor abuses continued for years after they were made illegal.

Unions were illegal in Britain until 1824, and could only function as mutual aid societies until 1870, when they could finally do collective bargaining. Owners saw unions as violation of free contract, and claimed workers couldn't handle leisure time, so were better off working all the time. The Combination Act of 1799 declared anyone joining an organization to improve working conditions was liable to a jail sentence of three months. One of the three magistrates passing sentence could be the defendant's boss. At one demonstration, seven women were jailed just for saying "bah!"

In general, the British labor movement and strikes were less violent than those in the United States, such as the Haymarket Riot, which took place May 4, 1886 in Chicago. Leading to this was growing pressure to make the 8-hour day standard for all workers by May 1, 1886. When that didn't happen, marches and demonstrations continued the following days. Anger in Chicago focused especially on a strike at the McCormick Harvesting Machine Company, which had brought in strikebreakers under police protection. On May 3 two strikers were killed by police, which sparked anarchists to call for a bigger rally at Haymarket Square the next day.

Despite some agitation for violence, the demonstration remained peaceful until about 10:30PM when police arrived in force and moved to disperse the crowd. At that point, someone threw a dynamite bomb that mortally wounded seven policemen. The police then opened fire, killing four and wounding many more, including some of their fellow police by accident. The number of civilians wounded remains unclear, since many were afraid to go to hospitals where they might be arrested.

The whole incident was over in five minutes, but the repercussions were long lasting. For one thing, five of the eight men charged with murder were born in Germany (as was Karl Marx), which fueled paranoia about foreign socialist agitators. It didn't help that the fliers advertising the demonstration were printed in both English and German. Therefore the Haymarket Riot and the Mayday holiday it was associated with, became popularly linked with the idea of the labor movement being a front for anarchists and communists. Conversely, this incident solidified Mayday as an international holiday for workers and was especially celebrated in communist countries such as the Soviet Union.

Another strike famous for its violence was the Pullman Strike (1894), also in Chicago, where thirteen strikers were killed and another fifty-seven were injured when federal troops were brought in to settle things down.

114. THE RISING STATUS OF WOMEN IN THE LATE 1800'S

One of the most dramatic and unexpected consequences of the Industrial Revolution was the rising status of women by the end of the nineteenth century. At this time there were competing crosscurrents affecting women's goals and aspirations. On the one hand, since the Later Middle Ages women in the West had experienced relatively high status compared to most other cultures. During the Enlightenment more positive attitudes about women had emerged and they had even taken active roles in during the French Revolution that followed. On the other hand, there were the still the traditional gender roles and ideas about a woman's places being in the home. These re-emerged during the Napoleonic era largely in reaction to the more active roles women had been playing. As a result, the 1800s saw women's status knocked back to their traditional domestic roles.

However, the industrial revolution changed the game in several ways. For one thing it created less need for men's greater physical strength, since machines were progressively taking over that role. Therefore, more women were entering the workplace and in some cases competing with men for jobs. Men disliked this, especially since factory owners who could more easily overwork and underpay them often preferred women. Therefore, working class men did what they could to push women out of what they saw as "male" occupations in order to keep their jobs. As a result, a further differentiation between men and women emerged in the 1800s between "male" occupations, which were counted in work statistics, and "female" occupations (especially domestic work outside of the home) that were not counted.

The industrial revolution had two other effects, especially concerning middle class women. For one thing, these more affluent women tended to stay home in what became associated with the "housewife" role. This gave many women more leisure time to read and become aware of society and its problems. Consequently, many of them got involved in political and social issues, typically through participation in church activities concerned with such causes and were considered safe for women to join.

At the same time, since many middle class women were also doing the shopping, they were seen as important aspects of the emerging consumer society. Therefore, the advertising industry targeted many of its campaigns specifically toward women. Ads showing women doing such things as dancing, ice skating, riding bicycles and playing golf created the perception that these were normal activities for women. In this case, life largely imitated art as women actually did go out and do those things. As a result, women's status in society as reflected in such ads started rising in the last half of the nineteenth century.

By the same token this rising status opened up new avenues of activity and expression for women. More women pursued secondary and university educations. Many of them also found their way into the workplace in what would eventually come to be seen as "female" occupations as nurses, teachers, and secretaries. In their leisure time, women took part in casual social dancing and sports. At first these were "feminine" sports such as croquet, bicycling, and horseback riding using the more "feminine" (and dangerous) sidesaddle. Even women's fashions in the early twentieth century reflected their social mobility by becoming increasingly less confining. More adventurous women were also taking part in mixed swimming and tennis. Only six years after the inauguration of men's singles at Wimbledon, women had their own singles tournament. Not only did women's rising status allow them to take part in these activities, but these activities gave women more visibility in society and increased their status, thus opening them more doors, and so on.

All this encouraged many women to work for suffrage (the right to vote). Serious discussion of this topic largely started with the French Revolution. Mary Wollstonecraft's book, *A Vindication of the Rights of Women* (1792), had, argued that women were neither mentally or physically inferior to men and that different standards for women were stifling to both sexes. This gained further support, including from such men as the political philosopher, John Stuart Mill. In Britain, demonstrations to gain the vote occasionally met with harsh reactions from men. When several women were jailed after a demonstration in 1905, newspapers finally broke their silence on the suffrage issue. This gave more

publicity and support for women's suffrage, which sparked more demonstrations, reactions, publicity and sympathy, and so on. Although some women, frustrated at their treatment, turned to more destructive and even violent actions (vandalism, bombs in mailboxes, and one woman even throwing herself in front of a racehorse), most kept to more moderate tactics and continued to gain support.

World War I accelerated this process when so many men were gone and women were needed to fill their jobs. In 1918, women over 30 who were householders, married to householders, or had a college degree won the vote (thus keeping male voters in the majority until 1928 when women over 21 could also vote). Women in other industrial countries soon gained suffrage: Finland (1906), Norway (1913), Russia (1917), and the United States (1919), along with Germany, Sweden, Austria, and the Netherlands. France, Italy, Switzerland and eventually most other countries around the globe would grant the vote later in the century. However, many barriers to equality remained and the struggle to attain equal status continues today.

A Short Guide to Victorian Etiquette

Above: the proper (left) and extremely vulgar way to dance in Victorian society

The informality of modern society would shock people from just about any previous age, but especially people in 19th century Britain during the reign of Queen Victoria (1837-1901). Following are just a few short rules on how to behave if you ever get caught in a time warp and end up in London c.1850.

- A lady never wears pearls or diamonds in the morning.
- A lady should never dance more than three dances in one night with the same gentleman.
- Guests should arrive precisely 15 min. after dictated, thus making them "fashionably late".
- Unmarried ladies under 30 may not be with an unrelated man or go anywhere without a chaperone.
- When meeting in public, a gentleman must wait for the lady to acknowledge him first.
- In a carriage, never sit next to a lady you're not related to and don't step on her dress.
- Weddings should be in AM or at least by 3PM with a wedding breakfast afterward.
- Upon departure for the honeymoon, guests throw shoes at the couple. (Failure to survive this ordeal bodes ill for the marriage.)
- Especially proper couples bring a lady friend of the bride's on the honeymoon.
- Victorian euphemisms: dark & white meat for legs & breast of fowl. Otherwise use "limb" instead of "leg", even if discussing a table limb, which should be covered with a tablecloth to protect the virtue of the table and any other innocent furniture in the room.
- Say "unmentionables" or "white sewing" instead of "underwear"
- Separate visitors to museums by gender in case a nude statue appears.
- People calling shouldn't bring dogs or kids, or call on wet days and drip on the rug.
- A lady being called on can send down a message that she isn't home.
- People with the same eye or hair color or body-type shouldn't marry each other.
- All men in a room should stand if there is one woman standing.
- A man shouldn't take something from a lady who is standing.
- Widows in mourning should wear black

for two years; one year for a child or parents; 6 months for a sibling; 2 months for an aunt or uncle. (15 seconds for a hamster)

- Victorian ladies were expected to make six wardrobe changes a day, depending on the activity: walking, visiting (“calling”), receiving (visitors), morning, mourning, traveling, shooting, golfing, swimming, concerting, dining, dancing, etc.

“Crazy” Women at Work and School

One argument given against women being educated was that insane asylums held more educated women than uneducated ones; therefore, education makes women insane. Of course, the same families that could afford to give their women educations also could afford to put them in such asylums, thus skewing the curve.

Speaking of treatment for the mentally ill, a major pioneer in that field was the American, Dorothea Dix who took up the cause after being told their living conditions were so horrid because "the insane do not feel heat or cold" She was also a major factor in making nursing an acceptable profession for women. As the Union's Superintendent of Female Nurses during the Civil War, she wanted to destroy the stereotype of women being too frail to handle the ghastly conditions of battlefield hospitals. Therefore, she would hire only plain looking women over the age of thirty.

While Florence Nightingale is best remembered for her efforts to make nursing a respectable career for women, Clara Barton did the same for American women during the Civil War. Her independent efforts to relieve the suffering of wounded soldiers (Confederate as well as Union) earned her the nickname “Angel of the Battlefield”. She would work so close to the combat, that one time a bullet passed through her sleeve and killed the wounded soldier she was tending. After the war, she traveled to Europe where she was influenced by the International Red Cross and inspired to start the

American Red Cross, which still thrives as an agency for disaster relief.

Between 1880 and 1900 the number of girls' schools in France went from zero to 138. In fact there were more girls than boys in school after age sixteen, probably because the boys had to go to work. Girls' schools also opened up teaching jobs to women, since it was considered inappropriate for men to teach girls.

The advantage of smaller hands. In the late 1800s, a new technology was taking over the office, the typewriter, which had the advantages of both speed and clarity over handwritten documents. It also was somewhat compact, thus favoring secretaries with smaller hands, which typically were women. As a result, typewriter ads from the time typically showed women working them.

Women's lack of rights. Many women in the 1800s were denied the right to own property or even dispose of their own paychecks. One Northeastern state allowed a husband to beat his wife as long as it was with a reasonable instrument. Men were almost always given custody of children in cases of divorce, mainly because women typically didn't have the independent means of supporting and raising children.

Margaret Sanger and the fight for birth control rights. Women then could also have their children taken from them if they publicly advocated birth control. The leading crusader for women's birth control rights was Margaret Sanger. After seeing so many women burdened with children and trapped in poverty, she became an early and persistent advocate for birth control in the 20th century, efforts which often landed her in jail. Her efforts eventually paid off when she and a researcher named Goody Pinkus developed the birth control pill in the 1950s and had it approved by the FDA in 1960.

Beating Corsets into Battleships

Note that corsets were also marketed for boys and children.

When the U.S. joined World War I in 1917, the U.S. War Industries Board asked women to stop buying corsets to free up metal for war production. This effort actually freed up enough steel to build two battleships, some 28,000 tons of metal. Largely replacing the corset was the brassiere, a much less confining garment, developed in the early 1900s, although it was not mass-produced until the 1930s. Another development in 1911, that of rubberized elastic materials gave rise to another garment to replace the corset, the girdle, which was worn for the purpose of reducing hip size.

In the 1950s, Maidenform started a long-running ad campaign where women would be doing various things in public, such as scaring small children at birthday parties, while wearing nothing over their Maidenform bras.

While the brassiere was much more liberating than the corset, many feminists in the 1970s

would see it as a symbol of the repression of women's bodies.

In a similar vein, while only women of ill repute wore makeup in the 1800s, women in the early 1900s fought to make the use of cosmetics acceptable. Actresses, such as Collene Moore and Clara Bow, especially popularized the use of makeup, which became a standard feature of the Flapper look in the 1920s. Today, a century later, many women again view cosmetics as demeaning.

Life Imitates Art (or the Other Way Around): Advertising and 19th Century Women

Did art, in particular, poster advertisements, imitate contemporary life in the late 1800s or vice versa? The best answer was probably yes, as the two fed back onto one another. Thus posters showing women dancing and engaging in outdoor sports and leisure activities both inspired women to step out into society and reflected the more active roles in which they were engaged, whether it be ice skating, terrorizing geese with a motorcycle, or crushing automobiles in their bare hands.

The Long Hard Road to Suffrage

Susan B. Anthony and Elizabeth Caty Stanton were two of the most important leaders of the Suffrage movement in the United States, starting with the Seneca Falls conference in July, 1848. Of the five women there, three were Quakers, the one Protestant sect that had allowed women to preach.

Suffrage terrorists. Some women went to more extreme lengths to publicize their cause. One suffragette, Emily Davison threw herself in front of the king's horse at the Epsom Derby (below) to publicize her cause (6/4/1913). The attempt cost the woman her life. Other suffragettes went to the extreme of putting bombs in opponents' mailboxes. Generally their protests were non-violent marches and hunger strikes. In the latter case, men would force feed the protestors.

Queen Victoria called the Suffrage Movement a "mad wicked folly".

Anti-suffrage propaganda also proliferated during the campaign to win the vote for women in the U.S. One poster entitled "America When Feminized" warns: "The More a Politician allows Himself to be Henpecked The More Henpecking We will Have in Politics." Then came the following by Dr. William J. Hickson, Chicago University:

"American pep which was the result of a masculine dominated county will soon be a thing of the past. With the collapse of the male ascendancy in this country we can look forward to a nation of degeneration. The suppression of sex will ultimately have its harvest in decadence, a phenomenon already beginning. The effect of the social revolution on American character will be to make sissies of American men—a process already well under way."

Wyoming was the first state in the United States to give women the vote, but not out of sympathy for women's rights. The U.S. constitution stipulated that for a territory to become a state, it needed 250,000 voters. Wyoming didn't have that many eligible *men*, but it did have that many eligible *voters* if it gave women the vote. So it did.

Passing the nineteenth amendment giving women the vote was a very close run affair. Two-thirds of the states had to ratify a proposed amendment for it to become part of the constitution. By 1920, thirty-five states had voted to ratify the amendment, one shy of the required thirty-six out of forty-eight. It all came down to the Tennessee legislature. After the first two roll calls were deadlocked, the youngest member of the legislature, Harry Burns, changed his vote in favor of the amendment and gave American women the vote.

Burns's change of vote enraged anti-suffragists, and there is an apocryphal story that he had to flee an angry mob by exiting through a third floor window and escaping by way of a window ledge to the attic where he hid until tempers cooled. When asked later why he changed his vote, he replied that his mother had sent him a telegram saying, "Don't forget to be a good boy and help Mrs. Catt [suffrage leader] put the "rat" in ratification." The next day he asked to speak to the legislature and explain his vote, saying his mother had always taught him that "a good boy always does what his mother asks him to do." So he did.

Margaret Sanger and the fight for birth control rights. Women then could also have their children taken from them if they publicly advocated birth control. The leading crusader for women's birth control rights was Margaret Sanger. After seeing so many women burdened with children and trapped in poverty, she became an early and persistent advocate for birth control in the 20th century, efforts which often landed her in jail. Her efforts eventually paid off when she and a researcher named Goody Pinkus developed the birth control pill in the 1950s and had it approved by the FDA in 1960.

115. SOCIALISM AND THE MARXIST VIEW OF HISTORY

"Religion is the opiate of the masses."--Karl Marx

One of the most powerful and influential philosophies of the nineteenth and twentieth centuries has been socialism, a doctrine believing the means of production should belong to the workers. This contrasts sharply with capitalism which has a small but very rich class of capitalists owning the means of production and an underclass of workers with little or no say in company policies. Socialism was a response to the horrible working and living conditions of the early industrial revolution. It was highly idealistic, even drawing inspiration from a tradition of early Christian communal societies. In fact, it was often too idealistic and democratic, which doomed many early socialist communal experiments, such as one in New Harmony, Indiana, to failure.

Much more radical was Marxism, named after its founder, Karl Marx, who published *The Communist Manifesto* in 1848. While early socialists tried to build a new order within the existing one, Marx believed the present order must first be destroyed by revolution before a truly socialist society could evolve. However, Marxism is more than just a revolutionary call to arms for the working class. It is an entire system of thought with its own all encompassing view of society, economics, and history.

To start with, Marx believed in *economic determinism*, the idea that how a society produces and distributes its wealth will determine its social and political structure, laws, and even religion. Thus he saw history as a series of class struggles as humanity evolved through five stages of society:

- 1) *Primitive hunting and gathering societies* which had no extra wealth and therefore no private property, social classes, class struggles, or even the need for government;
- 2) *Slave societies* with a rich ruling class opposed by an oppressed underclass of slaves;
- 3) *Feudal society* with a noble class of landowning lords opposed by an oppressed class of serfs;
- 4) *Capitalist society* with a rich class of factory owners (*bourgeoisie*) opposed by an oppressed class of factory workers (the proletariat); and finally

- 5) *Socialist society* run by the workers with no private property, and thus no social classes, or class conflicts.

Marx saw each type of society as a necessary stage in the evolution toward the socialist society. Likewise, he saw the capitalist society of his own time as self destructive and moving inevitably toward socialist revolution. This largely hinged on his *labor theory of value*, which stated that any product was only worth as much the workers were paid to make it. Anything a capitalist charged beyond this amount was called *surplus value*. And it was here that Marx saw the beginning of the fatal cycle that would destroy capitalism.

If capitalists charged more for a product than their workers were paid to make it, not everyone could sell their goods because, among other things, the workers would not be paid enough to buy them. This would drive some owners out of business and create a smaller business class, although individually they each would be richer. However, to stay competitive, they would have to invest in more efficient, and expensive, machinery, thus laying off workers in the process. Since they would still overcharge for their products and there were now even fewer workers to buy them, more owners would be driven from business and the cycle would repeat.

However, this cycle could not continue indefinitely, since each time around there would be a growing gap between the fabulously rich and desperately poor. Eventually, this would trigger a revolution that would destroy the capitalist order. The triumphant workers would then build a society where people as a whole owned everything in common. Private property would disappear, and with it social classes, conflict over property, and any need for government, family, and religion, which were all seen as instruments of bourgeois oppression. There would be no rich or poor, thus allowing each individual to find true fulfillment. However, for all of this to happen, an intermediate stage of government would be necessary to guide the revolution to this workers' utopia.

Marxism had both its good points and its problems. First of all, it was valuable for pointing out the importance of economics and class struggle in

history. On the other hand, it failed to account for the role of individual genius, stupidity, and especially greed in human affairs, assuming that everyone would voluntarily give up all individual possessions for the common good. Also, Marx assumed his socialist revolution would take place in industrialized countries, when in fact it actually occurred in pre-industrial societies such as Russia, China, and Cuba. This was largely because, by Marx's death in 1883, conditions for industrial workers were starting to improve, thus undercutting any appeal socialist revolution might have for them. However, many subsequent social reforms, both in countries that hated and feared Marxism as well as ones that followed it, could trace their existence back to Karl Marx.

116. THE SPREAD OF INDUSTRIALIZATION BEYOND BRITAIN (c.1850-1900)

By 1850, Britain had become the first industrialized country in the world, with over half of its people living in cities. It controlled ninety per cent of Europe's steam shipping along with half of the world's iron and two-thirds of its coal production. However, outside of Britain, industrial factories were few and far between. There were several reasons for this. For one thing, the competition of cheaper British goods drained the capital needed for investment in industry from other countries and toward Britain. Internal tolls and political disunity prevented the integration of national economies needed to industrialize. Coal and iron deposits were usually far from each other, making it hard to concentrate the resources needed for industrialization. Britain itself actively worked to keep its technical knowledge from leaking beyond its shores. Finally, there was widespread resistance to industrialization in other countries, as people were reluctant to give up their traditional ways, feared the loss of jobs to machines, and saw the pollution and squalor of Britain's cities at that time.

Being so far ahead of the rest of the world, Britain decided to hold a magnificent trade fair, The Great Exhibition, in 1851 to show off its technological achievements. Other countries also contributed exhibits, but Britain's were the centerpiece of the show. Among these was the exhibit hall itself, the Crystal Palace, a magnificent structure of iron and glass covering 19 acres and even enclosing the trees of Hyde P

ark. The Great Exhibition and Crystal Palace symbolized the completion of Britain's industrialization and the beginning of the spread of industry to other parts of Europe and the world. After 1850, the most spectacular industrial advances would take place in Western Europe, the United States, and Japan.

Despite the edge Britain was showing off in the Great Exhibition, there were five main factors pushing even harder for Western Europe and the United States to industrialize. First, British competition forced these countries to industrialize in order to survive. Secondly, British businesses found ready and cheaper opportunities for building railroads and industries in foreign countries, thus helping them industrialize. Along these lines,

Europe and America shared a common cultural heritage with Britain, including an aptitude for machines extending all the way back to the clocks and waterwheels of the Middle Ages. Along these lines, Britain was geographically close to the rest of Europe (and even the United States thanks to much faster steamships). Finally, constant contact with Britain meant that its knowledge could not be kept secret. Designs for steam engines and locomotives were bound to leak out, and they did with incredible impact. The first step most countries took to industrialize was to build railroads to link coal to iron deposits and factories to markets. Once a transportation system was in place, factory building and production could proceed.

Belgium was the first country after Britain to industrialize, largely because, being small and compact, its coal and iron deposits were near each other. Its government also established a national railroad in 1834 to tie the nation closer together. In France, as well, railroad construction, directed by Napoleon III and largely backed by British capital, led the way. By 1870, an extensive railway network radiated from Paris linking the agricultural south with the industrial centers in the north. Some said France did not experience an industrial *revolution* since it happened gradually and did not affect most Frenchmen who remained farmers. However, by 1900 France was a major industrial power following much the same pattern as other countries. Germany did not seriously start industrializing until after unification in 1871 when it could marshal all its resources in a concerted industrial effort. However, once unified, Germany saw a meteoric rise in its industrial might. Steel production doubled every decade from 1870 to 1900, passing even Great Britain in the 1890's. Its railroad mileage increased from 3500 in 1850 to 26,000 by 1900.

The United States saw even more dramatic industrial growth during this period because of its sheer size and plentiful resources. Railroads (also largely financed by British banks) had developed the interior east of the Mississippi by 1860. The completion of the first transcontinental railroad in 1869 symbolized the opening up of the vast interior west of the Mississippi, with its vast agricultural and mineral resources. Northern factories intensified production during the American Civil War of the 1860's and never let up. In 1870, Europe produced 60% of the world's manufactured goods.

By 1914, it had fallen to 40%, that drop being mainly caused by growing American industries.

One non-Western country, Japan, had also industrialized by 1900. Ironically, Japan had shut itself off from Western influences since the 1600's. But, in 1854 the United States forced Japan to trade with the West, and it decided to beat the West at its own game by industrializing. Few paid serious attention to this until 1903 when tiny Japan shocked the world by defeating Russia with its own largely mechanized forces. Japan had arrived as an industrial power, showing that the West's days as the undisputed masters of the globe were numbered.

Fun Facts and figures about Industrialization by 1850

The nineteenth century was the first century where large-scale statistical studies were carried out. Here are just a few of those statistics.

- From 1750 to 1830, textile production rose by a factor of 300-400 *times* in Britain.
- In 1850, London's coal consumption was greater than Prussia's coal production
- Similarly Britain's energy consumption was 155 times that of Russia

By comparison, the rest of Europe lagged far behind.

- France had 3 million textile workers in 1.5 million establishments.
- There were 6 tolls in the 37 mile stretch between Padua and Mantua, Italy
- A textile mill in Alsace sold its old machinery for scrap to another French company, which then installed it for continued use.

One way of viewing the overwhelming jump Britain had in industrializing is to think of a world map (above) where the size of countries is scaled to their coal production in 1850. On such a map, Britain, which produced two-thirds of the world's coal, would be twice as big as the rest of the world's countries combined:

The Crystal Palace & Great Exhibition of 1851

When the Great Exhibition was first announced, a contest was held to come up with an appropriately modern design of building to house it. However, none of the 240 entries was deemed suitable until a gardener, John Paxton, came up with the winning design: basically a giant greenhouse like the smaller ones he had built for his work.

Fun facts and figures about the Crystal Palace:

- It had 300,000 panes of glass, over 2000 iron girders, and 400 iron roof trusses.
- It was 1848 feet long, 456 feet wide, and 135 feet tall to clear the tops of the trees it would enclose. When sparrows became a nuisance, the Duke of Wellington suggested bringing in sparrow hawks.
- Its iron columns were set in place within 18 hours of casting in Birmingham.
- With no steam driven machinery to lift the girders, everything was done by horse power and a simple three legged hoist.
- It cost £150,000 (worth £12.6 million in 2010) to build and was finished in 17 weeks.
- The cast iron pillars were designed to handle surplus moisture from the trees' condensation
- The Crystal Palace contained the first public toilets (AKA "water closets" or "retiring rooms") that, for a penny, would get you a clean seat, towel, comb, and a shoeshine. Thus the old expression "spend a penny" was a polite way of saying going to the retiring room. The water closets earned 827,280 pennies.
- There were numerous fountains, with two jets spraying water to a height of 250 feet.
- The first two water towers built to power them collapsed from the weight of the water and were replaced by two even bigger ones.

Railroads offered special excursion rates to passengers from all over Britain, and clubs formed to take advantage of low rates.

There were 100,000 exhibits shown by 14,000 exhibitors, including printing presses, preserved pigs, locomotives, French perfumes, and a Prussian stove shaped like an armored knight. British exhibits included both old Medieval artifacts along with high tech locomotives, steam hammers, hydraulic presses, huge power looms, and engines to pull threshers.

There were glittery ornaments from the empire, such as furs, a fire engine, and a 20-man canoe from Canada. From India one could see a stuffed elephant, the Koh-i-noor diamond in a burglarproof contraption, and an official from the British East Indies Company explaining opium production to Queen Victoria, but probably not telling her it had addicted millions of Chinese.

From Europe there were largely luxury goods such as Belgian ruffles; French plates, perfume, carpets, Austrian beds and bookcases, and Spanish firearms. The U.S. showed a sewing machine and a McCormick reaper. The German industrial family, the Krupps, displayed a two-ton block of iron that crashed through the floor of the Crystal Palace, nearly killing several people.

Among the more interesting exhibits were a telegraph that let the Queen send a message to Edinburgh and an alarm bedstead that would hurl a sleeper into a cold bath. The inventor must have had teenage children.

Alarmists warned of anarchists who would assassinate Queen Victoria and Prince Albert and proclaim a Red Republic. Luckily there was no violence in the 23 weeks of the Exhibition, with only 12 pickpockets and 11 petty thieves removing small exhibits being caught. On a more optimistic note, the Crystal Palace inspired predictions that in the future, children would live as cucumbers under glass.

The British humor magazine, *Punch*, came up with the name Crystal Palace. It also showed satirical plans for a Crystal Tower to accompany it.

In 1854, the Crystal Palace was dismantled and rebuilt in Sydenham Hill, an affluent area of London. Unfortunately, it burned down in 1936.

Urban Renewal French style

In the 1850s, Napoleon III, emperor of France, put Baron Eugene von Haussman in charge of modern history's first urban renewal project in Paris. Such a project first required destroying 30,000 buildings, which naturally angered thousands of displaced Parisians who referred to Haussman as "Atilla the Expropriator." Haussman dictated a standard architectural style for the facades of new and surviving buildings to give an overall sense of unity to Paris. He also radically improved Paris' drainage and water supply, providing the city overall with much better hygiene.

Haussman laid down some 70 miles of new road and 400 miles of new pavement, replacing many of Paris' narrow streets with broad boulevards that Napoleon's opponents pointed out would be much harder to barricade during future revolutions. He also had half a million trees planted along the streets, making Paris a much more pleasing environment in which to live.

Napoleon III also built a new opera house (built 1862-75) that covered 120,000 square feet and had a stage that could hold 450 performers.

In 1855, Paris held its own International Exposition. Among its 24,000 exhibitors was the German industrial family, the Krupps, who this time displayed a five-ton block of iron that luckily didn't crash through any floors. So at the 1867 International Exposition in Paris, which had nearly 48,000 exhibitors, the Krupps tried their luck again with a forty-ton block of steel, with similarly unremarkable results. In 1914, the Krupps, then Germany's main arms and munitions manufacturer, would change their approach to damaging Paris by using massive artillery pieces to fire shells into the city from seventy miles away.

A Nation of “Blood and Iron”

If Bismarck dreamt of a strong Germany made of “blood and iron, the Krupp family largely made that dream come true. The Krupps owned a huge complex of factories in Essen, Germany (below) that, besides producing steel, was the primary supplier of arms and munitions to Germany through both world wars.

The conurbation of cities in the Ruhr district that grew up around Essen would contain 3.5 million people by 1910 with the Krupps lording over it as virtual princes. But then again, the superrich industrialists of the late nineteenth century were Europe’s (and America’s) new aristocracy. After World War II and the disarmament of Germany, the Krupps would hardly miss a beat, moving into the production of a new, more ominous type of product: kitchenware.

The down side of Germany’s rapid industrial expansion was that it led to many of the same social problems and tensions experienced in Britain and other industrializing nations. Living conditions were so crowded that two workers would often share a single bed, one working during the day and sleeping at night, and the other following a reverse schedule. One German artist who especially dramatized the plight of the working poor was Kathe Kollwitz, whose sketch (above left) translates roughly as “the survivors of the war of wars.” Bismarck’s biggest fear was a socialist revolution bred by these conditions.

The Suez Canal

The idea of a direct waterway between the Mediterranean and India had long been around and tried several times: by ancient pharaohs, the Persian king Darius I, and Ptolemy II. Those canals connected the Nile delta to the Red Sea, but encountered various problems such as silting, the Red Sea receding, and the higher level of the Red Sea than the Nile, which would cause salt water to flow into the river.

The modern route, which involved a longer canal, avoids the above problems by connecting two bodies of salt water that are roughly the

same elevation. Work started in 1859 as a joint project between the Egyptians and French, led by the French engineer, Ferdinand de Lesseps. When he started the project, de Lesseps employed 40,000 Egyptian laborers (largely forced labor) to provide the muscle. By the end of the project, he had replaced 30,000 of them with a 10,000 horsepower steam shovel. Finally in 1869, after a decade of hard work, cost overruns, and protests from Britain about forced labor (which De Lesseps pointed out the British themselves had used when building a railroad in Egypt), the Canal was finished, joining the Mediterranean and Red Seas and cutting the trip from Europe to Asia by 4,400 miles.

The canal, originally 102 miles (164 km) long and 26 feet (8 meters) deep, has been gradually enlarged to accommodate the progressively larger ships being built. As of 2010 it was 120 miles (193 km) long and 79 feet (24 m) deep, roughly three times its original depth.

Chicago: the City of Big Shoulders and Balloon Frame Houses

In 1820 Chicago, the city of “Big Shoulders” didn’t even exist as a village, let alone have shoulders. By the 1850s a new and more efficient style of house framing, called balloon framing (AKA *light wood*), was turning Chicago into the fastest growing city in America.

Balloon framing got its name because skeptics thought its use of thinner 2”x 4” studs made it as fragile as a balloon. Key to this new style was the Industrial Revolution that could mass-produce iron nails and standard sized lumber. Previously, iron nails were handmade and so expensive that there were laws against burning down one’s house in order to retrieve the iron nails for a new home. Thus house construction required the much more labor intensive and excruciatingly slow *post and beam* framing that used hand-sawn wood joined together by means of mortises and

tenons, handmade interlocking dovetail joints, or wooden pegs (below left). Balloon framing cut building costs by 40%, largely because framing a house, which before required 20 men, now supposedly could be done by one man and a boy.

Even the Great Chicago fire (October 8, 1871) barely slowed Chicago's growth. Within a few years, most of the damage had been rebuilt and few traces of the fire remained.

By the 1870s, cast iron construction had created buildings 5-6 stories high, and in 1885, steel and a new invention, the elevator made possible the first skyscraper of 10 stories. By 1891, another skyscraper, 21 stories tall, had been built.

[Back to flowchart](#)

116A ‘THE ONGOING CYCLE OF FOREIGN INVESTMENT AND SPREAD OF INDUSTRIALIZATION

Since Britain’s industrialization by the mid 1800s, there has been an ongoing cycle of foreign investment by industrial powers in the economies of developing nations that has spread industrialization across the globe. Very simply, as a nation would industrialize, it would experience a rise in the cost of labor and living. This would force it to raise the prices of its goods to keep up with the cost of production, making it less competitive in international markets and even at home. As their profit margins decline, businessmen start building industrial enterprises in non-industrial nations with cheap labor. While the industrialists’ profits rise, the new nation where they are investing becomes industrialized, starting the cycle all over again.

We can see three major waves of this cycle happening, although it has been a continuous process with occasional breaks (such as the two world wars) interrupting it. The first wave came after 1850, when industrialization spread to Western Europe, the United States, and Japan. The next wave came after World War II, at first rebuilding the war ravaged industries of Western Europe and Japan. Along with this came the development of the so-called “mini-dragons in East Asia (South Korea, Taiwan, Hong Kong, and Singapore). The early development by smaller states can be seen as analogous to the early development of the North Italian city-states in the High Middle Ages, while it took larger nation states longer to organize their resources.

The most recent, and still ongoing, wave since the early 1990s has seen the emergence of China and India as new industrial giants in the twenty-first century. Likewise, factories and jobs are being outsourced to South and South-East Asian nations such as Vietnam and Bangladesh.

117. THE QUICKENING PACE OF TECHNOLOGICAL CHANGE (c.1850-1900)

Throughout history, the slow pace of progress and the large gaps of time between new advances have generally made technological progress hard to perceive. However, since the mid-nineteenth century, one could hardly miss seeing the rapid evolution of technology at work. The key to this development was the fusion of science and technology in research laboratories resulting from three lines of development.

First of all, as the standard of living of the common people improved, they had money to buy goods. Sales and profits led to more production and jobs for more people, who also now had money to spend. This further improved the standard of living, leading to more sales, production, jobs, and so on, all of which generated the incentive to create new products to sell this growing consumer market.

The second and third lines of development were the parallel, but separate evolutions of science and technology. On the one hand, the Enlightenment spawned new discoveries and ideas in the fields of physics, biology, and chemistry. At the same time, Europeans' growing proficiency in machines produced the power loom, spinning jenny, steam engine, and locomotive in the late 1700s and early 1800s. However, until the 1800's, scientific and technological developments had rarely touched one another. But as technology became more sophisticated, it became increasingly obvious that further progress would depend on fusing it with the more abstract scientific knowledge that had been developing in the universities and labs.

Because of the more complex science and technology and the growing opportunities afforded by a growing consumer market, private companies and governments set up research laboratories where scientists could develop new inventions. No longer would technological progress rely on the random findings of brilliant but isolated inventors with little or no background in scientific knowledge. From this point on, science and technology were fused together into one of the most dynamic partnerships in history, triggering a cycle of new inventions generating more ideas and needs that led to more new inventions and so on. The result has been an incredible outpouring of new inventions and discoveries at an ever-accelerating pace, which continues to the present day. All this progress bred a new optimism and faith in the ability of science and technology to solve our problems. Some historians have even dubbed the period from 1870 to 1914 as the Age of Progress.

One could hardly give an exhaustive list of the new inventions and discoveries of the later 1800's, but just looking at some of the highlights shows the dramatic technological and scientific progress of this period. In transportation, we have already seen the impact of the railroads. Other developments further accelerated the pace at which the planet was being tied together. Steam powered ships reduced travel time at sea much as the steam locomotives did on land since ships were no longer dependent on tail winds for smooth sailing. By 1900, the automobile, powered by the internal combustion engine, was ushering in an age of fast personal travel that took individuals wherever and whenever they wanted independently of train schedules. In 1903, the internal combustion engine also allowed human beings to achieve their dream of powered flight. The sky was now the limit, and even that would not hold up, as the latter twentieth century would see flights to the moon and beyond.

Developments in communications were even more startling, led by the telegraph, which allowed messages to travel at the speed of electricity rather than the speed of a horse. When transoceanic cables were laid, the time it took to get a message from one side of the planet to the other was literally reduced from months to minutes. The invention of the telephone in 1876 made such communication more personal and accessible to the individual. Twenty years later, Marconi's invention of the wireless radio allowed a message to be broadcast to millions of people simultaneously without having to be directly linked by wire to each receiver. The world was effectively becoming a much smaller place.

Fuelling these new developments were new sources of energy. Petroleum powered the automobile, while natural gas was used extensively for lighting street lamps. Possibly most important of all was electricity, which could be transmitted over long distances and whose voltage could be adapted for use by small household appliances. Among these was Thomas Edison's lightbulb, providing homes with cheaper, brighter, and more constant light than the candle ever could provide.

Medical advances may have had the most significant impact of all on people's lives in the 1800's. Possibly the greatest single breakthrough in medical history was the nearly simultaneous discovery by the Frenchman Louis Pasteur and the Prussian Robert Koch of germ theory, the idea that microbes or germs cause disease. This led to advances in three ways. First, it gave doctors a direction in which to focus their searches for the

causes of various diseases. One by one, vaccines and treatments were found for such deadly sicknesses as malaria, tuberculosis, diphtheria, cholera, bubonic plague, and typhoid.

Secondly, it spawned a public health movement that provided covered sewers, clean water, and an overall more sanitary urban environment. Finally, it led to aseptic procedure, where surgeons practiced their art in a sterile environment, dramatically reducing the chances of a patient contracting further infection on the operating table. Add to this the use of ether as an anesthetic since the 1840's and transfusions and blood typing to compensate for blood loss during surgery, and patients had an excellent chance of survival. No wonder the average life expectancy rose by an unprecedented 15 years or more during the nineteenth century.

Agricultural production skyrocketed thanks to mechanical reapers and combines, steam tractors, hybrid crop strains, and chemical fertilizers. Growing knowledge in chemistry led to a thriving chemical industry, which produced soaps, alkalis, bleaches, dyes, vegetable oils, and a vast number of other products. New building materials were used. The formula for concrete, lost since the time of the Roman Empire, was rediscovered, while the Bessemer Process, which worked iron at much higher temperatures, leading to the production of high-grade steel. Together they made possible the architectural monument that best symbolized the modern age, the skyscraper. In addition, there were numerous other inventions to make life easier or more interesting: refrigeration, cameras, movies, and record players, to name a few.

This rapid and wide range of technological advances had profound economic, political, and even philosophical effects on Western Civilization and eventually the entire human race. Economically, we have become globally interdependent, since industries rely heavily on raw materials found only outside of their countries' borders while less industrialized nations rely on the goods those industrialized nations produce. Global interdependence in the 1800's led to a common worldwide gold standard to smooth over the complications of international trade. Although that gold standard has since been abandoned, the various national economies still operate as one integrated global economy. This has certain dangers as well, since the collapse of one nation's economy can trigger the collapse of others across the globe. The best-known example of this is the Great Depression of the 1930's, starting with the collapse of the United States' economy and then spreading worldwide.

The need for an integrated national economy with common railroad gauges and safety procedures and the elimination of internal tolls and other hindrances to trade has helped create the modern industrial state. New technologies, such as sophisticated and expensive modern weaponry that only governments can afford, faster communication to keep closer track of its citizens, and faster transport for moving its forces quickly to quell any civil disturbances have radically increased the modern industrial state's power over its population. Public education has been another outgrowth of the Industrial Revolution, teaching a nation's population a common body of knowledge and values, such as patriotism and living precisely according to the clock.

The Industrial Revolution has spawned new beliefs and weakened old ones. Longer life spans and the enticements of a higher standard of living have reduced the proportion of people deeply involved in religion. Instead, many people have chosen a more materialistic way of life. In fact, the philosophies of Materialism and Positivism emerged in the late 1800's, showing a growing faith in the potentials and values of material prosperity and modern science respectively. At the same time, Darwin's theory of evolution has emerged, seen by many as a threat to religion. Another powerful idea to emerge was Marxism, an economic and political philosophy that became a major force in the twentieth century.

Technology is certainly a double edged sword that has also created new problems such as pollution, overpopulation, the greenhouse effect, depletion of the ozone layer, and the threat of extinction from nuclear war. It has also been used to give us prosperity our ancestors could never have dreamed about. Whether it is ultimately used for our benefit or destruction is up to us and remains in the balance.

Car Bombs and Stanley Steamers

Riding in a "car bomb". To appreciate what a radical advance in technology the internal combustion engine and automobile were, we need to keep in mind that any such car is in essence an ongoing series of highly controlled explosions powered by a highly volatile fuel with the potential of turning the vehicle into a bomb in case of an accident. As a result, many people feared riding in the first automobiles, or the "internal explosion engine," as producers of the Stanley Steamer put it. That's the bad news. The good news is that the explosions very rarely get out of control. Also, that volatile fuel is a lot

lighter to carry around than a big boiler full of water and a load of coal to heat it to boiling point to produce steam.

Stanley Steamers. However, to be fair, very reliable steam powered cars, known as Stanley Steamers, were produced by the Stanley Motor Carriage Company from 1902-24. Its founders, twins Francis and Freelan Stanley, produced their first car (AKA the Locomobile) in 1897. Over the next two years, they produced and sold over 200 cars, more than any other U.S. carmaker. The Stanley Steamer used a vaporizing gasoline (later, kerosene) burner beneath a vertical fire-tube boiler, mounted under the seat. To keep the boiler light, it was reinforced by piano wire. It was actually quite safe and there are no documented boiler explosions. Greater power and the cheaper production costs of the internal combustion engine after 1910 made the Stanley Steamer obsolete.

There was even a steam-powered airplane that flew in 1933. It burned fuel oil, which was cheaper and less volatile than gasoline and was so quiet that you could hear the pilot yelling down to the crowd. Other reputed advantages over the internal combustion engine were it required less maintenance, was less likely to experience engine failure, required lower temperatures to heat the boiler, and was more efficient at low engine speeds and at higher altitudes where colder temperatures aided condensation to recapture water for the boiler.

The Panama Canal

Even more time-consuming than sailing around Africa was the trip around South America between the Atlantic and Pacific Oceans. Luckily, the Isthmus of Panama offered a relatively short route for digging a canal to avoid that long journey.

The Panama Canal was built in two stages. Between 1881 and 1888 it was a French project led by Ferdinand de Lesseps. Unfortunately, over 20,000 workers lost their lives to disease (especially malaria) and disasters (such as landslides) and construction was halted in 1888.

In 1904 the Americans picked up the banner, seeing the canal as vital to their interests. Since Columbia demanded a high price to let us build the canal through Panama (which it controlled at the time), the U.S. staged a revolution, getting a much better deal from a small and weak Panama

that owed its independence to the Yankees. Thanks to improvements in technology and the introduction of quinine against malaria, the canal was finished in 1914 at a cost of \$352 million.

Fun facts about the canal. At 51 miles in length, the Panama Canal cuts 8,000 miles off the trip from the Atlantic to the Pacific. The Pacific has a tidal range of 20' versus only 1' for the Atlantic, thus making it dangerous to navigate. Therefore they decided to build a series of 6 Locks, taking ships 85' above sea level but also saving 10 million cubic meters of excavation.

As you go from the Atlantic side to the Pacific side you're actually going from West to East. If you don't believe me, look at a map.

The water that used to raise and lower the Canal locks is fed by gravity from nearby Gatun Lake.

As ships have gotten larger, this has put a strain on the ability of the canal to accommodate them. Above, the USS Missouri barely fit through in 1945. It wouldn't even be close for aircraft carriers.

A Shrinking World

The telegraph represented a quantum leap in the speed at which news was transmitted. And it didn't stop at shorelines. The first telegraph cables laid under and across the English Channel (1850) and the Atlantic (1866) allowed news to be transmitted almost instantaneously across the globe, drastically shrinking peoples' perception of the size of the planet overnight. Promoters even called the Tran-Atlantic cable the eighth wonder of the world.

But laying the cable was no easy task. Cable ships laid out several thousand miles of steel-clad cable from coils below deck. Cable in shallower waters close to shore had extra armor to protect it from the greater potential damage caused by rocks, ships, and storms. Cable laid in deeper water was lighter, but still had to be able to support three miles of cable while being laid.

The long road to the telephone. While we tend to give one person credit for an invention, such as Alexander Graham Bell with the telephone, more often than not, such inventions are the result of the work of a number of people over time whose contributions are put together and synthesized into a final invention. Such was the case with the telephone.

I could start by telling how the heavy plow in the Middle Ages revolutionized agriculture, making the rise of towns in Western Europe possible, which helped kings build nation states that needed lots of money for their armies, triggering a mining boom in Germany that led to the problem not being able to pump water vertically more than 32 feet and Toricelli's experiment that gave us the invention of the barometer, which, when spun around generated an electrical current, leading to all sorts of experiments and traveling dog-and-pony shows using electricity. And I could tell you about Ben Franklin's near fatal experiments with flying kites in electrical storms) that saved the lives of billions of bell ringers and also about his attempts to electrocute a turkey (as a more humane way of killing it). But I won't.

Let's start in 1820 with the Danish scientist, H. C. Orsted, who was ending a lecture with an experiment to show there was no connection between electricity and magnetism by showing an electrical current passing down a wire wouldn't affect a nearby compass.

He was wrong, leading him to realize that an electric current had a magnetic field around it.

Five years later, the Englishman, William Sturgeon, was winding live wire around an iron bar, which created an electro-magnet. Michael Faraday reversed the process by spinning a magnet inside metal coil, electrified it. In 1857, the German Hermann von Helmholtz used an electro-magnet to attract a tuning fork, which vibrated with sound.

Finally, in 1876, Alexander Graham Bell put all these together with an invention where one talked into a metal membrane, causing a vibration that in turn created a fluctuation in an electro-magnetic coil that was passed by wire to another electro-magnet, which fluctuated in the same way, and was passed onto another metal membrane that reproduced the original sound. In other words, he had invented the telephone.

Nearly a century later in 1973, Dr. Martin Cooper made the first cell phone call to rival inventor, Joel Engel to tell him he had won the race to invent the cell phone.

Guglielmo Marconi and wireless telegraphy. Despite the seemingly miraculous advances in communications of the 1800s, they were all tied down to wires, thus limiting direct communication to two people, one at each end of the wire. In 1897, all that changed when the Italian inventor, Guglielmo Marconi, demonstrated his wireless radio telegraph in Britain over progressively longer distances. In 1901 he made the first transatlantic broadcast.

Marconi's system was first useful for communicating with ships at sea. It was radio distress signals that allowed other ships to come to the rescue of the Titanic's passengers in 1912. An early commercial use of the radio was a news service that would broadcast news to subscribing ships at sea.

Radio's real future lay in the coming century, when more powerful transmitters could broadcast messages, whether commercial, musical, or political, to millions of people simultaneously. Hitler would be among the first political leaders who would exploit this mass media, albeit for sinister purposes.

Among Marconi's other discoveries was that radio broadcasts travel farther at night than during the day.

Power and Light to the People

Edison's light bulb

The dark side of light. Until Edison's invention of the light bulb in 1878 made artificial lighting cheap and affordable, people generally were awake with the sun and slept when it got dark. Dinner parties were held during the full moon so

guests could find their way home. Abe Lincoln even won a court case by pointing out that the star witness' positive identification of the defendant as guilty of a nighttime crime was not possible because it took place when there was no moon.

The light bulb changed all that, causing modern lifestyles to diverge greatly from this pattern, thus contributing to sleep deprivation, various sleep disorders, and deaths from playing video games all night.

But for all that to happen, we needed electricity.

The first public power plant opened in 1881 in Surrey, UK, being powered by a nearby waterwheel. It ran several streetlights and local shops. The next year, Edison opened the first steam-powered power plant in London. However, these first generators were DC (direct current), which runs a higher risk of electrocution if not heavily insulated. Fortunately, Nicholas Tesla, having a better theoretical understanding of electricity, developed a system for alternating current (AC) that was safer to transmit over long distances and could allow the transformation between voltage levels in different parts of an electrical system. In 1891, using Tesla's patents for alternating current, Westinghouse opened a plant providing electricity to a mine in Telluride, Colorado over a 2.5-mile power line.

How a power plant works. It takes several steps to generate and deliver electricity to homes and factories. In terms of generating electricity, we still live very much in the age of steam. Even nuclear reactors heat water to produce steam and drive giant electro-magnetic dynamos. That's the easy part.

Then the electricity has to be stepped up by transformers to increase the voltage. High-tension wires then carry power to customers. However, to keep toasters and light bulbs from being overloaded by the current and exploding, step down transformers cut the voltage to levels safe for home and factory machines. Each country or region, such as the EU, has its own standard voltage and corresponding type of plug to which all appliances must conform before plugging in to the wall.

Safety tip: Don't take your hair drier to Europe if you want it to survive the trip. Even converters that adapt American 110-volt appliances to European 220-volt outlets have a tendency to overheat hair driers.

A Revolution in Medicine

A depiction of London's miasmatic air during the cholera outbreak in 1851
