The Nucleic Acids, DNA and RNA, are Polymers

The Dickerson Dodecamer

In the polymers (the nucleic acids DNA and RNA), the sugars are linked to each other through phosphoric acid groups attached to the 5' position of one sugar and the 3' position of the other.

This defines a direction to the backbone. The backbone bears a negative charge at physiological pH.

5' → 3'
shorthand notation (5' on left!)

The "base" is attached via a β -N-glycosidic bond.

2'-OH
Present in RNA
Absent in DNA

The Nucleosides

The Dickerson Dodecamer

Adenosine (A)

Guanosine (G)

Cytidine (C)

Thymidine (T)
(DNA only)

Uridine (U)
(RNA only)

Phospho mono esters can be hydrolyzed fairly easily under basic conditions, whereas Phospho di esters are resistant to basic hydrolysis.

Consequently, the DNA backbone has remarkable stability toward hydrolysis. (It has been estimated that the half-life for the hydrolysis of a phosphodiester at pH 7 and 37°C is 80×10^6 years!). DNA is stable, even on a prehistoric time scale!

The Phosphodiester Linkage Has Special Stability

Proteins are polymers (i.e., made of many parts).
Protein backbones are poly(amino acids): a linear sequence of α -amino acid building blocks that are joined together by peptide (amide) linkages. All amino acids (except glycine) have a stereogenic carbon (the α -carbon). Proteins are composed of [D or **L**] amino acids.

Amino Acids and Proteins

A Representative Peptide Sequence

Here's a portion of the N-terminal part of a linear polypeptide chain. Notice that the sequence is directional i.e., "N to C". To be more specific, the "N to C" direction of a peptide is found by locating the atom sequence **nitrogen**→**C_α**→**carbonyl carbon**.

The Aliphatic Amino Acids

Proteins are composed of 20 different α -amino acids. All of the structural and functional diversity among proteins can be attributed to the chemical differences found in this set of building blocks. Except for proline, all naturally occurring α -amino acids are [1° 2° 3°] amines. What makes them different is the side chains (-R) they bear.

The aliphatic α -amino acids

Glycine (Gly, G) —H

Alanine (Ala, A) —CH₃

Valine (Val, V)

Leucine (Leu, L)

Isoleucine (Ile, I)

- ✓ Branched
- ✓ Compact
- ✓ Bulky
- ✓ Hydrophobic

Ideal suited for:
packing & filling space

The Aromatic & Heterocyclic Amino Acids

The aromatic α -amino acids

The heterocyclic α -amino acids

Proline (Pro, P)

Histidine (His, H)

Tryptophan (Trp, W)

Sulfur and Hydroxyl-Containing Amino Acids

The sulfur-containing α -amino acids

Cysteine (Cys, C)

Methionine (Met, M)

Reversible crosslinks or **disulfide bridges**

The hydroxyl-containing α -amino acids

Serine (Ser, S)

Threonine (Thr, T)

Amino Acids with Positively Charged Groups

Amino Acids with Negative Charges and Their Derivatives

The acidic α -amino acids

Aspartate (Asp, D)

anionic under physiological conditions

Glutamate (Glu, E)

α -amino acids bearing primary amides

Asparagine (Asn, N)

Glutamine (Gln, Q)

The Protein Recipe of Life

How many amino acids make up a typical protein polymer? The plot at the right shows the size distribution of a sample of 2912 protein sequences.* The mean sequence length for this sample is 319 amino acids.

*see: S. H. White "Global Statistics of Protein Sequences" Annu. Rev. Biophys. Biomol. Struct. (1994) 23, 407-39

Protein Chains Fold into Unique 3D Structures

Factors that drive protein organization:

- The hydrophobic amino acids are buried in the core, excluding water.
- The surface is predominately hydrophilic amino acids that help maintain solubility.
- In the interior, the chain is arranged into secondary structures to "neutralize" the polar atoms through H-bonds.

globular proteins are compact and densely packed
amphiphilic molecules

Two renderings of the protein Lysozyme

Secondary Structures – The alpha-Helix

The α helix is one of the major elements of secondary structure in proteins. Backbone N and O atoms are hydrogen bonded to one another. The helix has a large dipole moment aligned parallel to the helical axis along the N to C direction. The side chains are oriented radially outward.

Secondary Structures – The Beta Sheet

antiparallel β -sheets

parallel β -sheets
